- ▶ Recognize anxiety related to test results, and be supportive of the potential perceived loss of body image. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of breast self-examination, mammography, magnetic resonance imaging (MRI) of the breast, or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society (ACS) recommends breast examinations be performed every 3 yr for women between the ages of 20 and 39 yr and annually for women over 40 yr of age; annual mammograms should be performed on women 40 yr and older as long as they are in good health. The ACS also recommends annual MRI testing for women at high risk of developing breast cancer. Genetic testing for inherited mutations (BRCA1 and BRCA2) associated with increased risk of developing breast cancer may be ordered for women at risk. The test is performed on a blood specimen. The most current guidelines for breast cancer screening of the general population as well as of individuals with increased risk are available from the ACS (www.cancer.org), the American College of Obstetricians and Gynecologists (ACOG) (www.acog.org), and the American College of Radiology (www.acr.org). Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy breast, cancer antigens, ductography, mammography, MRI breast, and US breast.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Synovial Fluid Analysis

SYNONYM/ACRONYM: Arthrocentesis, joint fluid analysis, knee fluid analysis.

COMMON USE: To identify the presence and assist in the management of joint disease related to disorders such as arthritis and gout.

SPECIMEN: Synovial fluid collected in a red-top tube for antinuclear antibodies (ANAs), complement, crystal examination, protein, rheumatoid factor (RF), and uric acid; sterile (red-top) tube for microbiological testing; lavender-top (EDTA) tube for mucin clot/viscosity, complete blood count (CBC) and differential; gray-top (sodium fluoride [NaFl]) tube for glucose; green-top (heparin) tube for lactic acid and pH.

NORMAL FINDINGS: (Method: Macroscopic evaluation of appearance; spectrophotometry for glucose, lactic acid, protein, and uric acid; Gram stain, acid-fast stain, and culture for microbiology; microscopic examination of fluid for cell count and evaluation of crystals; ion-selective electrode for pH; nephelometry for RF and C3 complement; indirect fluorescence for ANAs).

Test	Normal Result
Color	Colorless to pale yellow
Clarity	Clear
Viscosity	High
ANA	Parallels serum level
C3	Parallels serum level
Glucose	Less than 10 mg/dL of blood level
Lactic acid	5–20 mg/dL
pH	7.2–7.4
Protein	Less than 3 g/dL
RF	Parallels serum level
Uric acid	Parallels serum level
Crystals	None present
RBC count	None
WBC count	Less than 200/microL
Neutrophils	Less than 25%
WBC morphology	No abnormal cells or inclusions
Gram stain and culture	No organisms present
AFB smear and culture	No AFB present

AFB = acid-fast bacilli; ANA = antinuclear antibodies; C3 = complement; RBC = red blood cell; RF = rheumatoid factor; WBC = white blood cell.

DESCRIPTION: Synovial fluid analysis is performed via arthrocentesis, an invasive procedure involving

insertion of a needle into the joint space. Synovial effusions are associated with disorders or injuries

involving the joints. The most commonly aspirated joint is the knee, although samples also can be obtained from the shoulder, hip, elbow, wrist, and ankle if clinically indicated. Joint disorders can be classified into five categories: non-inflammatory, inflammatory, septic, crystal-induced, and hemorrhagic. The mucin clot test is used to correlate the qualitative assessment of synovial fluid viscosity with the presence of hyaluronic acid. The test is performed by mixing equal amounts of synovial fluid and 5% acetic acid solution on a glass slide and grading the ropiness of the subsequent clot as good, fair, or poor. Long, ropy strands are seen in normal synovial fluid.

This procedure is contraindicated for: N/A

INDICATIONS

- Administration of anti-inflammatory medications by injection
- Assist in the diagnosis of arthritis
- Assist in the evaluation of joint effusions
- Assist in the diagnosis of joint infection
- Differentiate gout from pseudogout

POTENTIAL DIAGNOSIS

Fluid values increased in

- **Acute bacterial infection:** Elevated WBC count with marked predominance of neutrophils (greater than 90% neutrophils), positive Gram stain, positive cultures, possible presence of rice bodies, increased lactic acid (produced by bacteria), and complement levels paralleling those found in serum (may be elevated or decreased)
- **Gout:** Elevated WBC count with a predominance of neutrophils

(90% neutrophils), presence of monosodium urate crystals, increased uric acid, and complement levels paralleling those of serum (may be elevated or decreased)

- **Osteoarthritis, traumatic arthritis degenerative joint disease:** Elevated WBC count with less than 25% neutrophils and the presence of cartilage cells
- **Pseudogout:** Presence of calcium pyrophosphate crystals
- **Rheumatoid arthritis:** Elevated WBC count with a predominance of neutrophils (greater than 70% neutrophils), presence of ragocyte cells and possibly rice bodies, presence of cholesterol crystals if effusion is chronic, increased protein, increased lactic acid, and presence of rheumatoid factor
- **Systemic lupus erythematosus (SLE):** Elevated WBC count with a predominance of neutrophils, presence of SLE cells, and presence of antinuclear antibodies
- **Trauma, joint tumors, or hemophilic arthritis:** Elevated RBC count, increased protein level, and presence of fat droplets (if trauma involved)
- **Tuberculous arthritis:** Elevated WBC count with a predominance of neutrophils (up to 90% neutrophils), possible presence of rice bodies, presence of cholesterol crystals if effusion is chronic, in some cases a positive culture and smear for acid-fast bacilli (results frequently negative), and lactic acid

Fluid values decreased in (analytes in parentheses are decreased)

- Acute bacterial arthritis (glucose and pH)
- Gout (glucose)
- Rheumatoid arthritis (glucose, pH, and complement)

- SLE (glucose, pH, and complement)
- Tuberculous arthritis (glucose and pH)

CRITICAL FINDINGS

Positive culture findings in any sterile body fluid.

Note and immediately report to the health-care provider (HCP) positive culture results, if ordered, and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Blood in the sample from traumatic arthrocentesis may falsely elevate the RBC count.
- Undetected hypoglycemia or hyperglycemia may produce misleading glucose values.
- Refrigeration of the sample may result in an increase in monosodium urate crystals secondary to decreased solubility of uric acid;

exposure of the sample to room air with a resultant loss of carbon dioxide and rise in pH encourages the formation of calcium pyrophosphate crystals.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing joint health.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and musculoskeletal systems, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the joint space. Explain that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the anesthetic injection may cause an initial stinging

sensation. Explain that, after the skin has been anesthetized, a large needle will be inserted through the joint space, and a “popping” sensation may be experienced as the needle penetrates the joint. Inform the patient that the procedure is performed by a health-care provider (HCP) specializing in this procedure. The procedure usually takes approximately 20 min to complete.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no fluid restrictions unless by medical direction. Fasting for at least 12 hr before the procedure is recommended if fluid glucose measurements are included in the analysis. Instruct the patient to avoid taking anti-coagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations; assure that food has been restricted for at least 12 hr prior to the procedure. Ensure that anticoagulant medications and aspirin have been withheld, as ordered.
- ▶ Assemble the necessary equipment, including an arthrocentesis tray with solution for skin preparation, local anesthetic, a 20-mL syringe, needles of various sizes, sterile drapes, and sterile gloves for the tests to be performed.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location, especially, right or left knee, shoulder, hip, elbow, wrist, or ankle.
- ▶ Assist the patient into a comfortable sitting or supine position, as appropriate.
- ▶ Use clippers to remove hair from the site prior to the administration of general or local anesthesia, cleanse the site with an antiseptic solution, and drape the area with sterile towels.
- ▶ After the local anesthetic is administered, the needle is inserted at the collection site, and fluid is removed by syringe. Manual pressure may be applied to facilitate fluid removal.
- ▶ If medication is injected into the joint, the syringe containing the sample is detached from the needle and replaced with the one containing the drug. The medication is injected with gentle pressure. The needle is withdrawn, and digital pressure is applied to the site for a few minutes. If there is no evidence of bleeding, a sterile dressing is applied to the site. An elastic bandage can be applied to the joint.
- ▶ Monitor the patient for complications related to the procedure (allergic reaction, anaphylaxis).
- ▶ Place samples in properly labeled specimen containers and promptly transport the specimens to the laboratory for processing and analysis. If bacterial culture and sensitivity tests are to be performed, record on the specimen containers any antibiotic therapy the patient is receiving.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet and medications, as directed by the HCP.
- ▶ After local anesthesia, monitor vital signs and compare with baseline values. Notify the HCP if temperature is

elevated. Protocols may vary among facilities.

- ▶ Observe/assess puncture site for bleeding, bruising, inflammation, and excessive drainage of synovial fluid approximately every 4 hr for 24 hr and daily thereafter for several days.
- ▶ Instruct the patient to report excessive pain, bleeding, or swelling to the requesting HCP immediately. Report to HCP if severe pain is present or the patient is unable to move the joint.
- ▶ Observe/assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Instruct the patient to apply an ice pack to the site for 24 to 48 hr.
- ▶ Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to anticipated chronic pain resulting from joint inflammation, impairment in mobility, musculoskeletal deformity, and loss of independence. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the

American College of Rheumatology (www.rheumatology.org) or for the Arthritis Foundation (www.arthritis.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient or caregiver to handle linen and dispose of dressings cautiously, especially if septic arthritis is suspected. Instruct the patient to avoid excessive use of the joint for several days to prevent pain and swelling. Instruct the patient to return for a follow-up visit as scheduled. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antibodies anti-cyclic citrullinated, ANA, arthrogram, arthroscopy, BMD, bone scan, CRP, cholesterol, CBC, CBC WBC count and differential, ESR, MRI musculoskeletal, radiography bone, RF, synovial fluid analysis, and uric acid.
- ▶ Refer to the Immune and Musculoskeletal systems tables at the end of the book for related tests by body system.

Syphilis Serology

SYNONYM/ACRONYM: Automated reagin testing (ART), fluorescent treponemal antibody testing (FTA-ABS), microhemagglutination-*Treponema pallidum* (MHA-TP), rapid plasma reagin (RPR), treponemal studies, Venereal Disease Research Laboratory (VDRL) testing.

COMMON USE: To indicate past or present syphilis infection.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Dark-field microscopy, rapid plasma reagin, enzyme-linked immunosorbent assay [ELISA], microhemagglutination, fluorescence) Nonreactive or absence of treponemal organisms.

DESCRIPTION: Syphilis is a sexually transmitted disease with three stages. On average, symptoms start within 3 weeks of infection but can appear as soon as 10 days or as late as 90 days after infection. The primary stage of syphilis is usually marked by the appearance of a single sore, called a chancre, at the site where the organism entered the body. The chancre is small and round in appearance, is firm, and is usually painless. The chancre lasts 3 to 6 weeks and heals with or without treatment. If untreated, the infection progresses to the secondary stage as the chancre is healing or several weeks after the chancre has healed. The secondary stage is characterized by a skin rash and lesions of the mucous membranes. Other symptoms may include fever, swollen lymph glands, sore throat, patchy hair loss, headaches, weight loss, muscle aches, and fatigue. As with the primary stage, the signs and symptoms of secondary syphilis will resolve either with or without treatment. If untreated, the infection will progress to the latent or hidden stage in which the infection and ability to transmit infection is present even though the infected person is asymptomatic. The latent stage begins when the primary and secondary symptoms disappear, and it can last for years. About 15% of people in the latent stage, who have not been treated, will develop late-stage syphilis, which can appear 10 to 20 years after infection. Untreated disease at this stage can result in significant damage to the brain, nerves, eyes, heart, blood vessels, liver, bones,

and joints—damage serious enough to cause death. Signs and symptoms of the late stage of syphilis include difficulty coordinating muscle movements, numbness, paralysis, blindness, and dementia.

There are numerous methods for detecting *Treponema pallidum*, the gram-negative spirochete bacterium known to cause syphilis. Syphilis serology is routinely ordered as part of a prenatal work-up and is required for evaluating donated blood units before release for transfusion. Selection of the proper testing method is important. Automated reagent testing (ART), rapid plasma reagin (RPR), and Venereal Disease Research Laboratory (VDRL) testing have traditionally been used for screening purposes. These nontreponemal assays detect antibodies directed against lipoidal antigens from damaged host cells. Nontreponemal assays can produce false-positive results, which are associated with older age or conditions unrelated to syphilis, such as autoimmune disorders or injection drug use, and require confirmation by a treponemal test method. Fluorescent treponemal antibody testing (FTA-ABS), microhemagglutination-*Treponema pallidum* (MHA-TP), and *Treponema pallidum* by particle agglutination (TP-PA) are confirmatory methods for samples that screen positive or reactive. Some laboratories have begun using a reverse-screening approach. Highly automated, rapid-testing treponemal enzyme immunoassays (EIA) and chemiluminescent assays (CIA) detect antibodies directed against

T. pallidum proteins. These assays detect early primary infections as well as past treated infections. The problem with the EIAs and CIAs is that they are very sensitive but less specific; therefore, positive test results should be confirmed using a nontreponemal assay. If reverse screening is used, the Centers for Disease Control and Prevention recommends (1) positive EIA/CIA be confirmed using the RPR and reactive RPR test results should be reported as the endpoint titer of reactivity; (2) a positive EIA/CIA followed by a nonreactive RPR should be tested by a direct treponemal assay such as the TP-PA or FTA-ABS to ensure a false-positive result is not reported and acted upon. Cerebrospinal fluid should be tested only by the FTA-ABS method. Cord blood should not be submitted for testing by any of the aforementioned methods; instead, the mother's serum should be tested to establish whether the infant should be treated.

This procedure is contraindicated for: N/A

INDICATIONS

- Monitor effectiveness of treatment for syphilis
- Screen for and confirm the presence of syphilis

POTENTIAL DIAGNOSIS

Positive findings in

- Syphilis

False-positive or false-reactive findings in screening (RPR, VDRL) tests

- Infectious:
 - Bacterial endocarditis
 - Chancroid
 - Chickenpox

- HIV
- Infectious mononucleosis
- Leprosy
- Leptospirosis
- Lymphogranuloma venereum
- Malaria
- Measles
- Mumps
- Mycoplasma pneumoniae
- Pneumococcal pneumonia
- Psittacosis
- Relapsing fever
- Rickettsial disease
- Scarlet fever
- Trypanosomiasis
- Tuberculosis
- Vaccinia (live or attenuated)
- Viral hepatitis
- Noninfectious:
 - Advanced cancer
 - Advancing age
 - Chronic liver disease
 - Connective tissue diseases
 - IV drug use
 - Multiple blood transfusions
 - Multiple myeloma and other immunological disorders
 - Narcotic addiction
 - Pregnancy

False-positive or false-reactive findings in confirmatory (FTA-ABS, MHA-TP) tests

- Infectious:
 - Infectious mononucleosis
 - Leprosy
 - Leptospirosis
 - Lyme disease
 - Malaria
 - Relapsing fever
- Noninfectious:
 - Systemic lupus erythematosus

False-positive findings in confirmatory (TP-PA) tests

- Infectious:
 - Pinta
 - Yaws

Negative findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Knowledge (<i>Related to new condition or diagnosis; lack of familiarity with or understanding of disease and treatment</i>)	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management	Identify sexual orientation; teach the process of disease transmission, heterosexual or homosexual activity; teach the patient that infection risk increases with the number of sexual partners over time; identify the patient's sexual activity; discuss importance of notifying sexual partners of disease exposure; assess for cultural, literacy, or vision and hearing concerns that would interfere with learning; teach the importance of taking the entire course of prescribed medication to treat the disease; administer prescribed medication; explore with the patient the value of monogamous relationship to support positive health
Infection	Rash on body; rash on the palms of the hands; rash on the soles of the feet; small firm nodules on genitalia, anus, or mouth; lack of coordinated movement; paralysis; gradual blindness; numbness; dementia; internal organ damage (brain, nerves, eyes, heart, liver, bones, joints); death at end stage	Assess for signs and symptoms of syphilis; ensure understanding that the disease is transmitted through direct contact with syphilis sores (located in genitalia, vagina, anus, inside the rectum, in the mouth); ensure understanding that it is a sexually transmitted disease; identify sexual partners who are at risk, notify them; assess for mucocutaneous infections; administer prescribed antibiotic

Problem	Signs & Symptoms	Interventions
Body image <i>(Related to the presence of lesions; rash)</i>	Focus on appearance (lesions, rash); states feelings of worthlessness due to physical changes; reports difficulty in coping with syphilis diagnosis; change in social interaction; withdrawal	Assess the patient's perception of physical changes; note the frequency of negative comments about changed physical state; assist in the identification of positive coping strategies to address changed physical appearance
Sexuality <i>(Related to alterations in sexual role secondary to syphilis infection)</i>	Hesitancy to discuss sexual relationship with significant other	Facilitate a discussion of realistic changes to sexual intimacy associated with syphilis disease; provide a relaxed atmosphere in which to discuss sexuality concerns; provide contact information for a support group

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing syphilis.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of exposure.
- ▶ Obtain a history of the patient's immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and offer support. Counsel the patient, as appropriate, regarding the risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen. Inform the patient that positive findings must be reported to local health department officials, who will question him or her regarding sexual partners. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Offer support, as appropriate, to patients who may be the victim of rape or sexual assault. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the patient may experience (e.g., guilt, depression, anger).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

- ▶ Inform the patient that repeat testing may be needed at 3-mo intervals for 1 yr to monitor the effectiveness of treatment.
- ▶ Provide information regarding vaccine-preventable diseases where indicated (e.g., sexually transmitted diseases such as hepatitis B and human papillomavirus). Provide contact information, if desired, for the CDC (www.cdc.gov/vaccines/vpd-vac).
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Educate the patient regarding access to counseling services.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding of the importance of notifying sexual partners of disease exposure
- ▶ States understanding that untreated syphilis can be passed to an unborn child resulting in multiple health problems including the possibility of death if untreated

Skills

- ▶ Describes the importance of a yearly gynecological exam to assess for sexually transmitted disease
- ▶ Demonstrates proficiency in the self-administration of antibiotic to treat syphilis infection

Attitude

- ▶ Complies with the request to notify exposed current sexual partners about diagnoses to decrease community risk
- ▶ Complies with the request to attend a support group to address specific concerns of self and sexual partner

RELATED MONOGRAPHS:

- ▶ Related tests include acid phosphatase, cerebrospinal fluid analysis, *Chlamydia* group antibody, culture bacterial anal, Gram stain, hepatitis B, hepatitis C, HIV, and β_2 -microglobulin.
- ▶ Refer to the Immune and Reproductive systems tables at the end of the book for related tests by body system.

Testosterone, Total

SYNONYM/ACRONYM: N/A

COMMON USE: To evaluate testosterone to assist in identification of disorders related to early puberty, late puberty, and infertility while assessing gonadal and adrenal function.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Immunochemiluminometric assay [ICMA])

Age	Conventional Units	SI Units (Conventional Units × 0.0347)
Cord blood		
Male	17–61 ng/dL	0.59–2.12 nmol/L
Female	16–44 ng/dL	0.56–1.53 nmol/L
1–5 mo		
Male	1–177 ng/dL	0.03–6.14 nmol/L
Female	1–5 ng/dL	0.03–0.17 nmol/L
6–11 mo		
Male	2–7 ng/dL	0.07–0.24 nmol/L
Female	2–5 ng/dL	0.07–0.17 nmol/L
1–5 yr		
Male and female	0–10 ng/dL	0.00–0.35 nmol/L
6–7 yr		
Male	0–20 ng/dL	0.00–0.69 nmol/L
Female	0–10 ng/dL	0.00–0.35 nmol/L
8–10 yr		
Male	0–25 ng/dL	0.00–0.87 nmol/L
Female	0–30 ng/dL	0–1 nmol/L
11–12 yr		
Male	0–350 ng/dL	0.00–12.1 nmol/L
Female	0–50 ng/dL	0.00–1.74 nmol/L
13–15 yr		
Male	15–500 ng/dL	0.52–17.35 nmol/L
Female	0–50 ng/dL	0.00–1.74 nmol/L
Adult–older adult		
Male	241–827 ng/dL	8.36–28.7 nmol/L
Female	15–70 ng/dL	0.52–2.43 nmol/L

	Tanner Stage	
	Male	Female
I	2–23 ng/dL	2–10 ng/dL
II	5–70 ng/dL	5–30 ng/dL
III	15–280 ng/dL	10–30 ng/dL
IV	105–545 ng/dL	15–40 ng/dL
V	265–800 ng/dL	10–40 ng/dL

DESCRIPTION: Testosterone is the major androgen responsible for sexual differentiation. In males, testosterone is made by the Leydig cells in the testicles and is responsible for spermatogenesis and the development of secondary sex characteristics. In females, the ovary and adrenal gland secrete small amounts of this hormone; however, most of the testosterone in females comes from the metabolism of androstenedione. In males, a testicular, adrenal, or pituitary tumor can cause an overabundance of testosterone, triggering precocious puberty. In females, adrenal tumors, hyperplasia, and medications can cause an overabundance of this hormone, resulting in masculinization or hirsutism.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of hypergonadism
- Assist in the diagnosis of male sexual precocity before age 10
- Distinguish between primary and secondary hypogonadism
- Evaluate hirsutism
- Evaluate male infertility

POTENTIAL DIAGNOSIS

Increased in

- Adrenal hyperplasia (*oversecretion of the androgen precursor dehydroepiandrosterone [DHEA]*)
- Adrenocortical tumors (*oversecretion of the androgen precursor DHEA*)
- Hirsutism (*any condition that results in increased production of testosterone or its precursors*)
- Hyperthyroidism (*high thyroxine levels increase the production of*

sex hormone-binding protein, which increases measured levels of total testosterone)

- Idiopathic sexual precocity (*related to stimulation of testosterone production by elevated levels of luteinizing hormone [LH]*)
- Polycystic ovaries (*high estrogen levels increase the production of sex hormone-binding protein, which increases measured levels of total testosterone*)
- Syndrome of androgen resistance
- Testicular or extragonadal tumors (*related to excessive secretion of testosterone*)
- Trophoblastic tumors during pregnancy
- Virilizing ovarian tumors

Decreased in

- Anovulation
- Cryptorchidism (*related to dysfunctional testes*)
- Delayed puberty
- Down syndrome (*related to diminished or dysfunctional testes*)
- Excessive alcohol intake (*alcohol inhibits secretion of testosterone*)
- Hepatic insufficiency (*related to decreased binding protein and reflects decreased measured levels of total testosterone*)
- Impotence (*decreased testosterone levels can result in impotence*)
- Klinefelter's syndrome (*chromosome abnormality XXY associated with testicular failure*)
- Malnutrition
- Myotonic dystrophy (*related to testicular atrophy*)
- Orchiectomy (*testosterone production occurs in the testes*)
- Primary and secondary hypogonadism
- Primary and secondary hypopituitarism
- Uremia

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase testosterone levels include barbiturates, bromocriptine, cimetidine, flutamide, gonadotropin, levonorgestrel, mifepristone, moclobemide, nafarelin (males), nilutamide, oral contraceptives, rifampin, and tamoxifen.
- Drugs that may decrease testosterone levels include cyclophosphamide, cyproterone, danazol, dexamethasone, diethylstilbestrol, digoxin, D-Trp-6-LHRH, fenoldopam, goserelin, ketoconazole, leuprolide, magnesium sulfate, medroxyprogesterone, methylprednisone, nandrolone, oral contraceptives, pravastatin, prednisone, pyridoglutethimide, spironolactone, stanozolol, tetracycline, and thioridazine.

NURSING IMPLICATIONS AND PROCEDURE**Potential Nursing Problems:**

Problem	Signs & Symptoms	Interventions
Sexuality (<i>Related to insufficient testosterone level</i>)	Delayed puberty; poor development of muscle mass; minimal body hair; insufficient penile and testicle growth; gynecomastia (breast development); arms and legs grow faster than the body trunk; erectile dysfunction; infertility; osteoporosis	Explain the importance of testosterone replacement therapy; administer prescribed testosterone replacement medication
Body image (<i>Related to altered male sexual development secondary to lack of testosterone</i>)	Negative verbalization of physical appearance and lack of male attributes; preoccupation with lack of physical body changes; distress and refusal to talk about appearance; negative verbalization about physical appearance	Assess the patient's perception of physical appearance; note the frequency of negative comments about lack of male attributes associated with physical appearance; assist in the identification of positive coping strategies to address inadequate male attribute physical appearance; provide reassurance that physical appearance may change with testosterone therapy; provide a referral to local support groups

(table continues on page 1424)

Problem	Signs & Symptoms	Interventions
Self-esteem (<i>Related to altered body image; functional impairment [erectile dysfunction]</i>)	Negative self comments; comments regarding difficulty dealing with health situation; indecisive behavior	Assess feelings regarding patient's sense of control over health management; provide an environment that will encourage the expression of feelings; assess the patient's feeling of being accepted and loved by others; use active listening; provide guidance as necessary to decrease anxiety

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with evaluating hormone levels.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and offer support, as

appropriate. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that lack of development of male attributes is due to inadequate testosterone

- ▶ States understanding of the importance of testosterone replacement to supporting male characteristic development

Skills

- ▶ Expresses the harmful effects of negative self-talk on self-esteem
- ▶ Reads provided referral information and agrees to attend an introductory meeting

Attitude

- ▶ Refrains from making negative self-comments associated with physical appearance
- ▶ Agrees to counseling in relation to concerns related to erectile dysfunction and intimacy

RELATED MONOGRAPHS:

- ▶ Related tests include angiography adrenal gland scan, ACE, antibodies antisperm, biopsy thyroid, chromosome analysis, CT renal, DHEAS, estradiol, FSH, LH, PTH, RAIU, semen analysis, thyroid scan, TSH, thyroxine, and US scrotal.
- ▶ Refer to the Endocrine and Reproductive systems tables at the end of the book for related test by body system.

Thyroglobulin

SYNONYM/ACRONYM: Tg.

COMMON USE: To evaluate thyroid gland function related to disorders such as tumor, inflammation, structural damage, and cancer.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Chemiluminescent enzyme immunoassay)

Age	Conventional Units	SI Units (Conventional Units x 1)
Premature infant		
1 day	107–395 ng/mL	107–395 mcg/L
3 days	49–163 ng/mL	49–163 mcg/L

(table continues on page 1426)

Age	Conventional Units	SI Units (Conventional Units × 1)
Cord blood	5–65 ng/mL	5–65 mcg/L
1 day	6–93 ng/mL	6–93 mcg/L
10 days	9–148 ng/mL	9–148 mcg/L
1 mo	17–63 ng/mL	17–63 mcg/L
7–12 yr	20–50 ng/mL	20–50 mcg/L
12–18 yr	9–27 ng/mL	9–27 mcg/L
Adult–older adult	0–50 ng/mL	0–50 mcg/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Thyroglobulin is secreted by normal, abnormal, and cancerous thyroid tissue cells.

- Differentiated thyroid cancer
- Graves' disease (untreated) (*auto-immune destruction of thyroid tissue cells*)
- Surgery or irradiation of the thyroid (*elevated levels indicate residual or disseminated carcinoma*)

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

- T₄-binding globulin deficiency
- Thyroiditis (*related to leakage from inflamed, damaged thyroid tissue cells*)
- Thyrotoxicosis

Decreased in

- Administration of thyroid hormone (*feedback loop suppresses production*)
- Congenital athyrosis (neonates) (*related to insufficient synthesis*)
- Thyrotoxicosis factitia

CRITICAL FINDINGS: N/A

Thyroid-Binding Inhibitory Immunoglobulin

SYNONYM/ACRONYM: Thyrotropin receptor antibodies, thyrotropin-binding inhibitory immunoglobulin, TBII, TRAb (TSH receptor antibodies).

COMMON USE: To assist in diagnosing Graves' disease related to thyroid function.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Electrochemiluminescence) 0.0–1.75 units/L.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Evidenced by antibodies that block the action of TSH and result in hyperthyroid conditions.

- Graves' disease
- Hyperthyroidism (various forms)
- Maternal thyroid disease
- Neonatal thyroid disease
- Toxic goiter

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Thyroid Scan

SYNONYM/ACRONYM: Iodine thyroid scan, technetium thyroid scan, thyroid scintiscan.

COMMON USE: To assess thyroid gland size, structure, function, and shape toward diagnosing disorders such as tumor, inflammation, cancer, and bleeding.

AREA OF APPLICATION: Thyroid.

CONTRAST: Oral radioactive iodine or IV technetium-99m pertechnetate.

DESCRIPTION: The thyroid scan is a nuclear medicine study performed to assess thyroid size, shape, position, and function. It is useful for evaluating thyroid nodules, multinodular goiter, and thyroiditis; assisting in the differential diagnosis of masses in the neck, base of the tongue, and mediastinum; and ruling out possible ectopic thyroid tissue in these areas. Thyroid scanning is performed after oral administration of radioactive iodine-123 (I-123) or I-131 or IV injection of technetium-99m (Tc-99m). Increased or decreased uptake by the thyroid gland and surrounding area and tissue is noted: Areas of increased radionuclide

uptake ("hot spots") are caused by hyperfunctioning thyroid nodules, which are usually nonmalignant; areas of decreased uptake ("cold spots") are caused by hypofunctioning nodules, which are more likely to be malignant. Ultrasound imaging may be used to determine if the cold spot is a solid, semicystic lesion or a pure cyst (cysts are rarely cancerous). To determine whether the cold spot depicts a malignant neoplasm, however, a biopsy must be performed.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant,

unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Assess palpable nodules and differentiate between a benign tumor or cyst and a malignant tumor
- Assess the presence of a thyroid nodule or enlarged thyroid gland
- Detect benign or malignant thyroid tumors
- Detect causes of neck or substernal masses
- Detect forms of thyroiditis (e.g., acute, chronic, Hashimoto's)
- Detect thyroid dysfunction
- Differentiate between Graves' disease and Plummer's disease, both of which cause hyperthyroidism
- Evaluate thyroid function in hyperthyroidism and hypothyroidism (analysis combined with interpretation of laboratory tests, thyroid function panel including thyroxine and triiodothyronine, and thyroid uptake tests)

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, contour, position, and function of the thyroid gland with homogeneous uptake of the radionuclide

Abnormal findings in

- Adenoma
- Cysts
- Fibrosis
- Goiter
- Graves' disease (diffusely enlarged, hyperfunctioning gland)
- Hematoma
- Metastasis
- Plummer's disease (nodular hyperfunctioning gland)
- Thyroiditis (Hashimoto's)
- Thyrotoxicosis
- Tumors, benign or malignant

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Other nuclear scans or iodinated contrast medium radiographic studies done within the previous 24 to 48 hr.
- Ingestion of foods containing iodine (iodized salt) or medications containing iodine (cough syrup, potassium iodide, vitamins, Lugol's solution, thyroid replacement medications), which can decrease the uptake of the radionuclide.
- Antithyroid medications (propylthiouracil), corticosteroids, antihistamines, warfarin, sulfonamides, nitrates, corticosteroids, thyroid hormones, and isoniazid, which can decrease the uptake of the radionuclide.
- Increased uptake of iodine in persons with an iodine-deficient diet or who are on phenothiazine therapy.
- Vomiting and severe diarrhea, which can affect absorption of orally administered radionuclide.
- Gastroenteritis, which can interfere with absorption of orally administered radionuclide.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue can produce erroneous hot spots.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or

patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating the thyroid glands structure and function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure thyroid blood tests are completed prior to this procedure.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodinated contrast medium or radioactive nuclides.
- ▶ Ensure that this procedure is performed before all radiographic procedures using iodinated contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test. Inform the patient that the procedure is performed in a nuclear medicine department, usually by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast for 8 to 12 hr prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injecting radionuclides are invasive procedures. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners;** hematoma **related to blood leakage into the tissue following needle insertion;** infection **that might occur if**

bacteria from the skin surface is introduced at the puncture site; or nerve injury ***that might occur if the needle strikes a nerve***.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary restrictions for 8 to 12 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to lie still during the procedure because movement produces unclear images.
- ▶ Administer sedative to a child or to an uncooperative adult, as ordered.
- ▶ Tc-99m pertechnetate is injected IV 20 min before scanning.
- ▶ If oral radioactive nuclide is used instead, administer I-123 24 hr before scanning.
- ▶ Place the patient in a supine position on a flat table to obtain images of the neck area.
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Advise the patient to drink increased amounts of fluids for 24 to 48 hr to

eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.

- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to flush the toilet immediately and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, angiography adrenal, biopsy thyroid, calcium, CT renal, cortisol, glucose, radioactive iodine uptake, sodium, thyroglobulin, thyroid antibodies, TBII, thyroid scan, TSH, TT₃, T₄, FT₄, and US thyroid.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Thyroid-Stimulating Hormone

SYNONYM/ACRONYM: Thyrotropin, TSH.

COMMON USE: To evaluate thyroid gland function related to the primary cause of hypothyroidism and assess for congenital disorders, tumor, cancer, and inflammation.

SPECIMEN: Serum (1 mL) collected in a gold-red- or tiger-top tube; for a neonate, use filter paper.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 1)
Neonates–3 days	Less than 40 micro-international units/mL	Less than 40 milli-international units/L
2 wk–5 mo	1.7–9.1 micro-international units/mL	1.7–9.1 milli-international units/L
6 mo–1 yr	0.7–6.4 micro-international units/mL	0.7–6.4 milli-international units/L
2 yr–19 yr	0.5–4.5 micro-international units/mL	0.5–4.5 milli-international units/L
Greater than 20 yr	0.4–4.2 micro-international units/mL	0.4–4.2 milli-international units/L
Pregnancy		
First Trimester	0.3–2.7 micro-international units/mL	0.3–2.7 milli-international units/L
Second Trimester	0.5–2.7 micro-international units/mL	0.5–2.7 milli-international units/L
Third Trimester	0.4–2.9 micro-international units/mL	0.4–2.9 milli-international units/L

DESCRIPTION: Thyroid-stimulating hormone (TSH) is produced by the pituitary gland in response to stimulation by thyrotropin-releasing hormone (TRH), a hypothalamic-releasing factor. TRH regulates the release and circulating levels of thyroid hormones in response to variables such as cold, stress, and increased meta-

bolic need. Thyroid and pituitary function can be evaluated by TSH measurement. TSH exhibits diurnal variation, peaking between midnight and 4 a.m. and troughing between 5 and 6 p.m. TSH values are high at birth but reach adult levels in the first week of life. Elevated TSH levels combined with decreased thyroxine (T_4)

levels indicate hypothyroidism and thyroid gland dysfunction. In general, decreased TSH and T_4 levels indicate secondary congenital hypothyroidism and pituitary hypothalamic dysfunction. A normal TSH level and a depressed T_4 level may indicate (1) hypothyroidism owing to a congenital defect in T_4 -binding globulin or (2) transient congenital hypothyroidism owing to hypoxia or prematurity. Early diagnosis and treatment in the neonate are crucial for the prevention of cretinism and mental retardation.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of congenital hypothyroidism
- Assist in the diagnosis of hypothyroidism or hyperthyroidism or suspected pituitary or hypothalamic dysfunction
- Differentiate functional euthyroidism from true hypothyroidism in debilitated individuals

POTENTIAL DIAGNOSIS

Increased in

A decrease in thyroid hormone levels activates the feedback loop to increase production of TSH.

- Congenital hypothyroidism in the neonate (filter paper test)
- Ectopic TSH-producing tumors (lung, breast)
- Primary hypothyroidism (*related to a dysfunctional thyroid gland*)

- Secondary hyperthyroidism owing to pituitary hyperactivity
- Thyroid hormone resistance
- Thyroiditis (Hashimoto's autoimmune disease)

Decreased in

An increase in thyroid hormone levels activates the feedback loop to decrease production of TSH.

- Excessive thyroid hormone replacement
- Graves' disease
- Primary hyperthyroidism
- Secondary hypothyroidism (*related to pituitary involvement that decreases production of TSH*)
- Tertiary hypothyroidism (*related to hypothalamic involvement that decreases production of TRH*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and hormones that may increase TSH levels include amiodarone, benserazide, erythrosine, flunarizine (males), iobenzamic acid, iodides, lithium, methimazole, metoclopramide, morphine, propranolol, radiographic agents, TRH, and valproic acid.
- Drugs and hormones that may decrease TSH levels include acetylsalicylic acid, amiodarone, anabolic steroids, carbamazepine, corticosteroids, glucocorticoids, hydrocortisone, interferon- α -2b, iodamide, levodopa (in hypothyroidism), levothyroxine, methergoline, nifedipine, T_4 , and triiodothyronine (T_3).
- Failure to let the filter paper sample dry may affect test results.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Nutrition (<i>Related to slow metabolism</i>)	Decreased appetite with weight gain; selection of high-calorie, high-sodium foods; sedentary lifestyle; caloric intake greater than metabolic needs; constipation; decreased activity	Teach the patient to avoid foods with high sodium, saturated fat, and cholesterol content; teach the patient to eat a diet high in protein and low in calories to promote weight loss; encourage the patient to eat small, frequent meals to prevent overeating and enhance weight control; encourage the consumption of high-fiber foods such as fruits and vegetables with the skins and whole-grain breads to improve gastric motility; monitor daily weight; accurately assess appetite and measure caloric intake over a 24-hr period; arrange dietary consult
Decreased cardiac output (<i>Related to a deficit of thyroid hormone</i>)	Bradycardia; lethargy; hypotension; decreased thyroid hormone levels; fatigue; activity intolerance; poor peripheral perfusion; cool skin; shortness of breath	Assess and trend vital signs and blood pressure; monitor and trend thyroid laboratory studies (TSH, T3, T4, RAIU); assess cardiac status indicators—peripheral pulses, skin color, skin temperature, dry scaly skin); assess for periorbital edema; administer prescribed thyroid hormone replacement medication; facilitate measures to improve patient warmth (blankets, warm clothing and liquids, warmer environment); pace activity and schedule rest periods to manage fatigue; use pulse oximetry to monitor oxygen saturation; assess respiratory status checking for crackles and increased respiratory rate; monitor for fluid overload

(table continues on page 1434)

Problem	Signs & Symptoms	Interventions
Altered thought processes <i>(Related to decreased cardiac output and impaired cerebral perfusion secondary to a deficit of thyroid hormone)</i>	Altered memory; mental impairment; decreased concentration; depression; inaccurate environmental perception; inappropriate thinking; memory deficits	Minimize apprehension and dread; collaborate with the health-care provider (HCP) to manage medical problem associated with decreased cerebral perfusion; promote comprehension and understanding of current events; provide a modified environment that promotes safety; monitor the ability to provide self-care (activities of daily living); monitor injury risk (violence, fall risk, self-harm risk); administer prescribed thyroid hormone replacement medication
Self-esteem <i>(Related to chronic illness; physiologic impairment associated with thyroid hormone deficiency)</i>	Negative self-evaluation; negative evaluation of personal abilities; expressions of shame or guilt; seeks excessive reassurance; exaggerates negative feedback; indecisive; passive; nonassertive; conforming	Facilitate a positive outlook based on real rather than exaggerated factors that influence health; facilitate acknowledgement of personal strengths and values; provide a safe environment for verbalization of concerns; collaborate with patient in designing an appropriate plan of care; collaborate with patient in promoting effective decision making; monitor frequency of negative self-comments; promote the concept of counseling to improve the concept of self-worth; use role-play and modeling to improve positive behavioral skills; provide information about community resources for continued counseling

PRETEST:

▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

▶ **Patient Teaching:** Inform the patient this test can assist in evaluating thyroid function.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix F).

▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.

▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

▶ Promptly transport the specimen to the laboratory for processing and analysis.

Filter Paper Test (Neonate)

▶ Obtain kit and cleanse heel with antiseptic. Observe standard precautions, and follow the general guidelines in Appendix A. Perform heel stick, gently squeeze infant's heel, and touch filter paper to the puncture site. Use gauze to dry the stick area completely. When

collecting samples for newborn screening, it is important to apply each blood drop to the correct side of the filter paper card and fill each circle with a single application of blood. Overfilling or underfilling the circles will cause the specimen card to be rejected by the testing facility. Additional information is required on newborn screening cards and may vary by state. Newborn screening cards should be allowed to air dry for several hours on a level, nonabsorbent, unenclosed area. If multiple patients are tested, do not stack cards. State regulations usually require the specimen cards to be submitted within 24 hr of collection.

POST-TEST:

▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

▶ Recognize anxiety related to test results and answer any questions or address any concerns voiced by the patient or family.

▶ Educate the patient and family regarding the effects of hypothyroidism on the body over time.

▶ Educate the family regarding safety interventions that can be taken in the event that the patient becomes confused.

Expected Patient Outcomes:

Knowledge

▶ States understanding of reporting difficulty breathing to facilitate timely interventions

▶ States understanding of the importance of taking thyroid replacement therapy to overall health

Skills

- ▶ Demonstrates proficiency in designing a dietary strategy that encompasses the concept of six small meals a day to better manage caloric needs
- ▶ Identifies ways to conserve energy and prevent fatigue associated with compromised cardiac status

Attitude

- ▶ Complies with the HCP's recommendation of a dietary consult to assist in managing caloric needs appropriately

- ▶ Complies with taking thyroid replacement medication as prescribed

RELATED MONOGRAPHS:

- ▶ Related tests include albumin, antibodies antithyroglobulin, biopsy thyroid, copper, newborn screening, PTH, protein, RAIU, thyroglobulin, TSI, TBII, thyroid scan, T₄, free T₄, T₃, free T₃, and US thyroid.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Thyroid-Stimulating Immunoglobulins

SYNONYM/ACRONYM: Thyrotropin receptor antibodies, Thyroid-Stimulating Immunoglobulins, TRAb (TSH receptor antibodies).

COMMON USE: To differentiate between antibodies that stimulate or inhibit thyroid hormone production related to disorders such as Graves' disease.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Animal cell transfection with luciferase marker) Less than 130% of basal activity.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Graves' disease (*this form of hyperthyroidism has an autoimmune*

component; the antibodies stimulate release of thyroid hormones outside the feedback loop that regulates TSH levels)

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Thyroxine-Binding Globulin

SYNONYM/ACRONYM: TBG.

COMMON USE: To evaluate thyroid hormone levels related to deficiency or excess to assist in diagnosing disorders such as hyperthyroidism and hypothyroidism.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunochemiluminometric assay [ICMA])

Age	Conventional Units	SI Units (Conventional Units × 10)
0–1 wk	3–8 mg/dL	30–80 mg/L
1–12 mo	1.6–3.6 mg/dL	16–36 mg/L
14–19 yr	1.2–2.5 mg/dL	12–25 mg/L
Greater than 20 yr	1.3–3.3 mg/dL	13–33 mg/L
Pregnancy, third trimester	4.7–5.9 mg/dL	47–59 mg/L
Oral contraceptives	1.5–5.5 mg/dL	15–55 mg/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Acute intermittent porphyria (*pathophysiology is unclear*)
- Estrogen therapy (*TBG is increased in the presence of exogenous or endogenous estrogens*)
- Genetically high TBG (rare)
- Hyperthyroidism (*related to increased levels of total thyroxine available for binding*)
- Infectious hepatitis and other liver diseases (*pathophysiology is unclear*)
- Neonates
- Pregnancy (*TBG is increased in the presence of exogenous or endogenous estrogens*)

Decreased in

- Acromegaly
- Chronic hepatic disease (*related to general decrease in protein synthesis*)
- Genetically low TBG
- Major illness (*related to general decrease in protein synthesis*)
- Marked hypoproteinemia, malnutrition (*related to general decrease in protein synthesis*)
- Nephrotic syndrome (*related to general increase in protein loss*)
- Ovarian hypofunction (*TBG is decreased in the absence of estrogens*)
- Surgical stress (*related to general decrease in protein synthesis*)
- Testosterone-producing tumors (*TBG is decreased in the presence of testosterone*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Thyroxine, Free

SYNONYM/ACRONYM: Free T_4 , Free $_4$.

COMMON USE: A complementary laboratory test in evaluating thyroid hormone levels related to deficiency or excess to assist in diagnosing hyperthyroidism and hypothyroidism.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 12.9)
Newborn	0.8–2.8 ng/dL	10–36 pmol/L
1–12 mo	0.8–2 ng/dL	10–26 pmol/L
1–18 yr	0.8–1.7 ng/dL	10–22 pmol/L
Adult–older adult	0.8–1.5 ng/dL	10–19 pmol/L
Pregnancy (1st trimester)	0.9–1.4 ng/dL	12–18 pmol/L
Pregnancy (2nd trimester)	0.7–1.3 ng/dL	9–17 pmol/L

DESCRIPTION: Thyroxine (T_4) is a hormone produced and secreted by the thyroid gland. Most T_4 in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free T_4 , which is the physiologically active form. Levels of free T_4 are proportional to levels of total T_4 . The advantage of measuring free T_4 instead of total T_4 is that, unlike total T_4 measurements, free T_4 levels are not affected by fluctuations in TBG levels; as a result, free T_4 levels are considered the most accurate indicator of T_4 and its thyrometabolic activity. Free T_4 measurements are useful in evaluating thyroid disease when thyroid-stimulating hormone (TSH) levels alone provide insufficient

information. Free T_4 and TSH levels are inversely proportional. Measurement of free T_4 is also recommended during treatment for hyperthyroidism until symptoms have abated and levels have decreased into the normal range.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate signs of hypothyroidism or hyperthyroidism
- Monitor response to therapy for hypothyroidism or hyperthyroidism

POTENTIAL DIAGNOSIS

Increased in

- Hyperthyroidism (*thyroxine is produced independently of stimulation by TSH*)

- Hypothyroidism treated with T₄ (*laboratory tests do not distinguish between endogenous and exogenous sources*)

Decreased in

- Hypothyroidism (*thyroid hormones are not produced in sufficient quantities regardless of TSH levels*)
- Pregnancy (late)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase free T₄ levels include acetylsalicylic acid, amiodarone, halofenate, heparin, iopanoic acid, levothyroxine, methimazole, and radiographic agents.
- Drugs that may decrease free T₄ levels include amiodarone, anabolic steroids, asparaginase, methadone, methimazole, oral contraceptives, and phenylbutazone.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Decreased cardiac output (<i>Related to a deficit of thyroid hormone</i>)	Bradycardia; lethargy; hypotension; decreased thyroid hormone levels; fatigue; activity intolerance; poor peripheral perfusion; cool skin; shortness of breath	Assess and trend vital signs and blood pressure; monitor and trend thyroid laboratory studies (TSH, T3, T4, RAIU); assess cardiac status indicators—peripheral pulses, skin color, skin temperature, dry scaly skin); assess for periorbital edema; administer prescribed thyroid hormone replacement medication; facilitate measures to improve patient warmth (blankets, warm clothing and liquids, warmer environment); pace activity and schedule rest periods to manage fatigue; use pulse oximetry to monitor oxygen saturation; assess respiratory status checking for crackles and increased respiratory rate; monitor for fluid overload
Altered thought processes (<i>Related to decreased cardiac</i>)	Altered memory; mental impairment;	Minimize apprehension and dread; collaborate with the health-care provider (HCP)

(table continues on page 1440)

Problem	Signs & Symptoms	Interventions
<i>output and impaired cerebral perfusion secondary to a deficit of thyroid hormone)</i>	decreased concentration; depression; inaccurate environmental perception; inappropriate thinking; memory deficits	to manage medical problem associated with decreased cerebral perfusion; promote comprehension and understanding of current events; provide a modified environment that promotes safety; monitor the ability to provide self-care (activities of daily living); monitor injury risk (violence, fall risk, self-harm risk); administer prescribed thyroid hormone replacement medication
Body image (<i>Related to the presence of goiter and exophthalmos</i>)	Eye bulging from exophthalmos; enlarged neck from goiter; distress and refusal to talk about changed appearance; negative verbalization about changes in appearance; uses clothing or other devices to hide changed appearance (scarves, high necks, sunglasses)	Assess the patient's perception of physical changes; note the frequency of negative comments about changed physical state; assist in the identification of positive coping strategies to address changed physical appearance
Elevated temperature (<i>Related to increased basal metabolic rate</i>)	Elevated temperature; flushed; warm skin; diaphoresis	Assess the patient's temperature frequently; monitor for emotionally labile events that could precipitate a thyroid storm or crisis and precipitate an elevation in temperature; ensure the patient's immediate environment remains cool; encourage the use of light bedding and lightweight clothing to

Problem	Signs & Symptoms	Interventions
		prevent overheating; increase fluid intake to offset insensible fluid loss; encourage bathing with tepid water for comfort and promotion of cooling; administer prescribed antithyroid therapy

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing thyroid gland function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the

- patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Recognize anxiety related to test results, and answer any questions or address any concerns voiced by the patient or family.

Teach the family and patient about the relationship between the development of goiter and exophthalmos and hyperthyroidism.

Expected Patient Outcomes:

Knowledge

- States understanding of symptoms that may indicate a thyroid storm
- Identifies symptoms that would indicate hypothyroidism

Skills

- Demonstrates proficiency in selecting clothing that will assist in remaining cool and prevent overheating
- Demonstrates proficiency in the self-administration of thyroid or

anti-thyroid medication correctly as prescribed

Attitude

- Displays acceptance of changed appearance and refrains from negative self-comments
- Complies with recommended medication regime

RELATED MONOGRAPHS:

- Related tests include albumin, antibodies antithyroglobulin, biopsy thyroid, copper, PTH, prealbumin, protein, RAIU, thyroglobulin, TBII, thyroid scan, TSH, TSI, T₄, T₃, free T₃, and US thyroid.
- Refer to the Endocrine System table at the end of the book for related tests by body system.

Thyroxine, Total

SYNONYM/ACRONYM: T₄.

COMMON USE: A first look at thyroid function and a tool to evaluate the effectiveness of therapeutic thyroid therapy.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 17.1)
Cord blood	6.6–17.5 mcg/dL	113–299 nmol/L
1–30 days	5.4–22.6 mcg/dL	92–386 nmol/L
1 mo–23 mo	5.4–16.6 mcg/dL	92–284 nmol/L
2–6 yr	5.3–15 mcg/dL	91–256 nmol/L
7–11 yr	5.7–14.1 mcg/dL	98–241 nmol/L
12–19 yr	4.7–14.6 mcg/dL	80–250 nmol/L
Adult	4.6–12 mcg/dL	79–205 nmol/L
Pregnant female	5.5–16 mcg/dL	94–274 nmol/L
Over 60 yr	5–10.7 mcg/dL	86–183 nmol/L

DESCRIPTION: Thyroxine (T_4) is a hormone produced and secreted by the thyroid gland. Most T_4 in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free T_4 , which is the physiologically active form. Levels of free T_4 are proportional to levels of total T_4 . The advantage of measuring free T_4 instead of total T_4 is that, unlike total T_4 measurements, free T_4 levels are not affected by fluctuations in TBG levels; as a result, free T_4 levels are considered the most accurate indicator of T_4 and its thyrometabolic activity (see monograph titled “Thyroxine, Free”). Untreated deficiency of T_4 in newborns can result in untreatable, severe intellectual deficits and growth impairment. Neonatal screening for hypothyroidism is mandatory in all 50 states.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate signs of hypothyroidism or hyperthyroidism and neonatal screening for congenital hypothyroidism (required in all 50 states)
- Evaluate thyroid response to protein deficiency associated with severe illnesses
- Monitor response to therapy for hypothyroidism or hyperthyroidism

POTENTIAL DIAGNOSIS

Increased in

- Acute psychiatric illnesses (*pathophysiology is unknown, although there is a relationship between thyroid hormone levels and certain types of mental illness*)

- Excessive intake of iodine (*iodine is rapidly taken up by the body to form thyroxine*)
- Hepatitis (*related to decreased production of TBG by damaged liver cells*)
- Hyperthyroidism (*thyroxine is produced independently of stimulation by TSH*)
- Obesity
- Thyrotoxicosis due to Graves' disease (*thyroxine is produced independently of stimulation by TSH*)
- Thyrotoxicosis factitia (*laboratory tests do not distinguish between endogenous and exogenous sources*)

Decreased in

- Decreased TBG (*nephrotic syndrome, liver disease, gastrointestinal protein loss, malnutrition*)
- Hypothyroidism (*thyroid hormones are not produced in sufficient quantities regardless of TSH levels*)
- Panhypopituitarism (*dysfunctional pituitary gland does not secrete enough thyrotropin to stimulate the thyroid to produce thyroxine*)
- Strenuous exercise

CRITICAL FINDINGS

- **Hypothyroidism:** Less than 2 mcg/dL (SI: Less than 34.2 nmol/L)
- **Hyperthyroidism:** Greater than 20 mcg/dL (Greater than 342 nmol/L)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will

vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

At levels less than 2 mcg/dL, the patient is at risk for myxedema coma. Signs and symptoms of severe hypothyroidism include hypothermia, hypotension, bradycardia, hypoventilation, lethargy, and coma. Possible interventions include airway support, hourly monitoring for neurological function and blood pressure, and administration of IV thyroid hormone.

At levels greater than 20 mcg/dL, the patient is at risk for thyroid storm. Signs and symptoms of severe hyperthyroidism include hyperthermia, diaphoresis, vomiting, dehydration, and shock. Possible interventions include supportive treatment for shock, fluid and electrolyte replacement for dehydration, and administration of antithyroid drugs (propylthiouracil and Lugol's solution).

INTERFERING FACTORS

• Drugs that may increase T_4 levels include amiodarone, amphetamines, corticosteroids, ether, fluorouracil, glucocorticoids, halofenate, insulin, iobenzamic acid, iopanoic acid, ipodate, levarterenol, levodopa, levothyroxine, opiates, oral contraceptives, phenothiazine, and prostaglandins.

• Drugs, substances, and treatments that may decrease T_4 levels include acetylsalicylic acid, aminoglutethimide, aminosalicic acid, amiodarone, anabolic steroids, anti-convulsants, asparaginase, barbiturates, carbimazole, chlorpromazine, chlorpropamide, cholestyramine, clofibrate, cobalt, colestipol, corticotropin, cortisone, cotrimoxazole, cytostatic therapy, danazol, dehydroepiandrosterone, dexamethasone, diazepam, diazo dyes (e.g., Evans blue), dinitrophenol, ethionamide, fenclufenac, halofenate, hydroxyphenylpyruvic acid, interferon alfa-2b, iothiouracil, iron, isotretinoin, liothyronine, lithium, lovastatin, methimazole, methylthiouracil, mitotane, norethindrone, penicillamine, penicillin, phenylacetic acid derivatives, phenylbutazone, potassium iodide, propylthiouracil, reserpine, salicylate, sodium nitroprusside, stanozolol, sulfonyleureas, tetrachlorothyronine, tolbutamide, and triiodothyronine (T_3).

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing thyroid gland function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation

and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include albumin, antibodies antithyroglobulin, biopsy thyroid, copper, newborn screening, PTH, pre-albumin, protein, RAIU, thyroglobulin, TBil, thyroid scan, TSH, TSI, free T_4 , T_3 , free T_3 , and US thyroid.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Toxoplasma Antibody

SYNONYM/ACRONYM: Toxoplasmosis serology, toxoplasmosis titer.

COMMON USE: To assess for a past or present toxoplasmosis infection and to assess for the presence of antibodies.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Chemiluminescent immunoassay)

	IgM	Interpretation	IgG	Interpretation
Negative	0.89 index or less	No significant level of detectable antibody	6.4 IU/mL or less	No significant level of detectable antibody; indicative of nonimmunity
Indeterminate	0.9–1 index	Equivocal results; retest in 10–14 d	6.5–7.9 IU/mL	Equivocal results; retest in 10–14 d
Positive	1.1 index or greater	Antibody detected; indicative of recent immunization, current or recent infection	8 IU/mL or greater	Antibody detected; indicative of immunization, current or past infection

DESCRIPTION: Toxoplasmosis is a severe, generalized granulomatous central nervous system disease caused by the protozoan *Toxoplasma gondii*. The disease is more common in warm, humid climates at lower altitudes. Domestic and related cats are the only known definitive hosts for oocysts of *Toxoplasma gondii*. Intermediate hosts become infected by ingesting the oocysts which then transform into the tachyzoite form. Tachyzoites migrate to neural and muscle tissue and develop into tissue cysts. Transmission to humans occurs by ingesting undercooked meat of infected animals, handling contaminated matter such as cat litter, drinking contaminated water, receiving a blood product transfusion or organ transplant from an infected donor, or across the placenta from mother to fetus. Immunoglobulin (Ig) M antibodies develop approximately 5 days after infection and can remain elevated for 3 wk to several months. IgG antibodies develop 1 to 2 wk after infection and can

remain elevated for months or years. Healthy patients who become infected may not exhibit any symptoms or if symptoms are present they may be vague and common to other conditions. Some patients may develop lesions in the eye which can inflame the retina and form scars upon resolution. Successive reactivation of the inflammation can lead to progressive loss of vision. *T. gondii* serology is part of the TORCH (toxoplasmosis, other [congenital syphilis and viruses], rubella, cytomegalovirus, and herpes simplex type 2) panel routinely performed on pregnant women. Fetal infection during the first trimester can cause spontaneous abortion or congenital defects such as microcephaly, microphthalmia, hydranencephaly, and hydrocephalus. Immunocompromised individuals are also at high risk for serious complications if infected. While most healthy people recover without treatment, pregnant women, newborns, infants, and immunocompromised patients a

receive effective treatment until the worst symptoms have passed and the infection resolves. However, the location of the parasite makes it difficult to completely eradicate with medications. The presence of IgM antibodies indicates acute or congenital infection; the presence of IgG antibodies indicates current or past infection.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in establishing a diagnosis of toxoplasmosis
- Document past exposure or immunity
- Serological screening during pregnancy

POTENTIAL DIAGNOSIS

Positive findings in

- Toxoplasma infection

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Knowledge (<i>Related to recent diagnosis; complexity of treatment; poor understating of provided information; cultural or language barriers; anxiety; emotional disturbance; unfamiliarity with medical management</i>)	Possibility that there will not be symptoms if the individual has a healthy immune system	Teach the patient and family that toxoplasmosis infection is caused by the <i>Toxoplasma gondii</i> parasite; teach the patient and family that parasite infection is caused from eating undercooked or contaminated pork, lamb, venison
Infection (<i>Related to inadequate meat preparation [pork, lamb, venison]; accidental ingestion after handling contaminated meat and not washing hands; drinking contaminated water; swallowing contaminated cat feces; accidentally ingesting contaminated soil; pregnancy [mother-child]</i>)	Absence of symptoms; flu-like symptoms (muscular aches, pains, swollen glands); reduced or blurred vision; eye redness; tearing; eye lesion; infected	Teach the patient that if the immune system is healthy and the patient is not pregnant, treatment may not be necessary; teach the patient that if eye lesions are present an ophthalmologist may need to be consulted; administer prescribed medications to patients who are HIV positive or are immunosuppressed

(table continues on page 1448)

Problem	Signs & Symptoms	Interventions
Fear (<i>Related to fetal injury secondary to parasite infection during pregnancy</i>)	<p>newborns can have serious eye and brain damage at birth</p> <p>Verbalization of fear; restlessness; increased tension; continuous questioning; increased blood pressure, heart rate, respiratory rate</p>	<p>Evaluate verbal and nonverbal indicators of fear; assess for the cause of fear; acknowledge the patient's awareness of his or her fear; explain all procedures with simple age-appropriate and culturally appropriate language; administer prescribed mild tranquilizer; maintain a confident, assured professional manner in all patient interactions</p>
Noncompliance (<i>Related to refusal to accept new diagnosis; financial instability; cultural norms; complexity of the medical management; lack of knowledge</i>)	<p>Insufficient disease management; continued use of raw or contaminated food or water for diet and food preparation</p>	<p>Assess the patient's ability to understand and comply with health recommendations; assess for personal factors that may limit the patient's ability to understand such as cognitive and hearing factors; assess the level of family support; ensure the patient knows the signs and symptoms related to the disease process; teach correct food preparation and how to prevent at-risk activities related to contamination by soil or cat feces; refer to social services as appropriate</p>

PRETEST:

▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

▶ **Patient Teaching:** Inform the patient this test can assist in assessing for toxoplasmosis infection.

▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

▶ Obtain a history of exposure.

▶ Obtain a history of the patient's immune and reproductive systems, a history of other potential sources of exposure, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm the diagnosis. Any individual positive result should be repeated in 3 wk to monitor a change in detectable level of antibody. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and provide emotional support if results are positive and the patient is pregnant and/or immunocompromised. Discuss the implications of abnormal test results

on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Instruct the patient in isolation precautions during time of communicability or contagion.
- ▶ Emphasize the need to return to have a convalescent blood sample taken in 3 wk.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that raw or undercooked pork, lamb, or venison can cause a parasitic infection
- ▶ States importance of washing hands after emptying cat litter box to prevent parasitic infection

Skills

- ▶ Describes food preparation activities that demonstrate understanding of correct meat preparation and cooking time
- ▶ Demonstrates proficient hand-washing technique

Attitude

- ▶ Recognizes the importance of making lifestyle changes to support the health of themselves and family
- ▶ Complies with the recommendation to take special precautions to avoid at-risk activities during pregnancy

RELATED MONOGRAPHS:

- ▶ Related tests include CMV, fetal fibronectin, rubella, and viral culture.
- ▶ Refer to the Immune and Reproductive systems tables at the end of the book for related tests by body system.

Transferrin

SYNONYM/ACRONYM: Siderophilin, TRF

COMMON USE: To assess circulating iron levels related to dietary intake to assist in diagnosing disorders such as iron deficiency anemia or hemochromatosis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Nephelometry)

Age	Conventional Units	SI Units (Conventional Units × 0.01)
Newborn	130–275 mg/dL	1.3–2.75 g/L
1–9 yr	180–330 mg/dL	1.8–3.3 g/L
10–19 yr	195–385 mg/dL	1.95–3.85 g/L
Adult		
Male	215–365 mg/dL	2.2–3.6 g/L
Female	250–380 mg/dL	2.5–3.8 g/L

DESCRIPTION: Transferrin is a glycoprotein formed in the liver. Its role is the transportation of iron, obtained from dietary intake or RBC breakdown; normally one-third of available transferrin is saturated. Inadequate transferrin levels can lead to impaired hemoglobin synthesis and anemia. Transferrin is subject to diurnal variation, and it is responsible for the variation in levels of serum iron throughout the day. (See monograph titled “Iron-Binding Capacity [Total], Transferrin, and Iron Saturation.”)

This procedure is contraindicated for: N/A

INDICATIONS

- Determine the iron-binding capacity of the blood
- Evaluate iron metabolism in iron-deficiency anemia

- Evaluate nutritional status
- Screen for hemochromatosis

POTENTIAL DIAGNOSIS

Increased in

- Estrogen therapy (*estrogen stimulates the liver to produce transferrin*)
- Iron-deficiency anemia (*the liver produces transferrin in response to decreased iron levels*)
- Pregnancy (*the liver produces transferrin in response to anemia of pregnancy*)

Decreased in

- Acute or chronic infection (*a negative acute-phase reactant protein whose levels decrease in response to inflammation*)
- Cancer (especially of the gastrointestinal tract) (*related to malnutrition*)
- Excessive protein loss from renal disease (*related to increased loss from damaged kidney*)

- Hepatic damage (*related to decreased synthesis in the liver*)
- Hereditary atransferrinemia
- Malnutrition (*related to a protein-deficient diet that does not provide the nutrients required for synthesis*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase transferrin levels include carbamazepine, danazol, mestranol, and oral contraceptives.
- Drugs that may decrease transferrin levels include cortisone and dextran.
- Transferrin levels are subject to diurnal variation and should be collected in the morning, when levels are highest.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating for anemia.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen

collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for at least 12 hr before specimen collection.
- ▶ Note that there are no fluid or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions; ensure that food has been restricted for at least 12 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, as directed by the HCP.

▶ **Nutritional Considerations:** Educate the patient with abnormal iron values that numerous factors affect the absorption of iron, enhancing or decreasing absorption regardless of the original content of the iron-containing dietary source. Patients must be educated to either increase or avoid intake of iron and iron-rich foods depending on their specific condition; for example, a patient with hemochromatosis or acute pernicious anemia should be educated to avoid foods rich in iron. Consumption of large amounts of alcohol damages the intestine and allows increased absorption of iron. A high intake of calcium and ascorbic acid also increases iron absorption. Iron absorption after a meal is also increased by factors in meat, fish, and poultry. Iron absorption is decreased by the absence (gastric resection) or diminished presence (use of antacids) of gastric acid. Phytic acids from cereals, tannins from tea and coffee, oxalic acid from vegetables, and minerals such as copper, zinc, and manganese interfere with iron absorption.

▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Educate the patient regarding access to nutritional counseling services. Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
 ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▶ Related tests include A/G, cancer antigens, CBC, CBC RBC count, CBC RBC indices, CBC RBC morphology, ferritin, iron/TIBC, prealbumin, and total protein.
 ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Triglycerides

SYNONYM/ACRONYM: Trigs, TG.

COMMON USE: To evaluate triglyceride levels to assess cardiovascular disease risk and evaluate the effectiveness of therapeutic interventions.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Spectrophotometry)

ATP III Classification	Conventional Units	SI Units (Conventional Units × 0.0113)
Normal	Less than 150 mg/dL	Less than 1.7 mmol/L
Borderline high	150–199 mg/dL	1.7–2.2 mmol/L
High	200–499 mg/dL	2.2–5.6 mmol/L
Very high	Greater than 500 mg/dL	Greater than 5.6 mmol/L

DESCRIPTION: Fat or adipose is an important source of energy. Triglycerides (TGs) are a combination of three fatty acids and one glycerol molecule. Much of the fatty acids used in various metabolic processes come from dietary sources. However, the body also generates fatty acids, from available glucose and amino acids, that are converted into glycogen or stored energy by the liver. Beyond triglyceride, total cholesterol, high-density lipoprotein (HDL), and low-density lipoprotein (LDL) cholesterol values, other important risk factors must be considered. In November 2013, new guidelines for the prevention of cardiovascular disease (CVD) were developed by the American College of Cardiology (ACA) and the American Heart Association (AHA) in conjunction with members of the National Heart, Lung, and Blood Institute's (NHLBI) ATP IV Expert Panel. The updated, evidence-based guidelines redefine the condition of concern as atherosclerotic cardiovascular disease (ASCVD) and expand ASCVD to include CVD, stroke, and peripheral artery disease. Some of the important highlights include:

- Movement away from the use of LDL cholesterol targets in determining treatment with statins. Recommendations that focus on selecting (a) the patients that fall into four groups most likely to benefit from statin therapy, and (b) the level of statin intensity most likely to affect or reduce development of ASCVD.
- Development of a new 10-yr risk assessment tool based on findings from a large, diverse population. Evidence-based risk factors include age, sex, ethnicity, total cholesterol, high-density

lipoprotein (HDL) cholesterol, blood pressure, blood-pressure treatment status, diabetes, and current use of tobacco products.

- Recommendations for aspects of lifestyle that would encourage prevention of ASCVD to include adherence to a Mediterranean- or DASH (Dietary Approaches to Stop Hypertension)-style diet; dietary restriction of saturated fats, trans fats, sugar, and sodium; and regular participation in aerobic exercise. The guidelines contain reductions in BMI cut-offs for men and women designed to promote discussions between HCPs and their patients regarding the benefits of maintaining a healthy weight.
- Recognition that additional biological markers, such as family history, high-sensitivity C-reactive protein, ankle-brachial index (ABI), and coronary artery calcium (CAC) score may be selectively used with the assessment tool to assist in predicting and evaluating risk.
- Recognition that other biomarkers such as apolipoprotein B, eGFR, creatinine, lipoprotein (a) or Lp (a), and microalbumin warrant further study and may be considered for inclusion in future guidelines.

Triglyceride levels vary by age, gender, weight, and race:

Levels increase with age.

Levels are higher in men than in women (among women, those who take oral contraceptives have levels that are 20 to 40 mg/dL higher than those who do not).

Levels are higher in overweight and obese people than in those with normal weight.

Levels in African Americans are approximately 10 to 20 mg/dL lower than in whites.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate known or suspected disorders associated with altered triglyceride levels
- Identify hyperlipoproteinemia (hyperlipidemia) in patients with a family history of the disorder
- Monitor the response to drugs known to alter triglyceride levels
- Screen adults who are either over 40 yr or obese to estimate the risk for atherosclerotic cardiovascular disease

POTENTIAL DIAGNOSIS

Increased in

- Acute myocardial infarction (*elevated TG is identified as an independent risk factor in the development of CAD*)
- Alcoholism (*related to decreased breakdown of fats in the liver and increased blood levels*)
- Anorexia nervosa (*compensatory increase secondary to starvation*)
- Chronic ischemic heart disease (*elevated TG is identified as an independent risk factor in the development of CAD*)
- Cirrhosis (*increased TG blood levels related to decreased breakdown of fats in the liver*)
- Glycogen storage disease (*G6PD deficiency, e.g., von Gierke's disease, results in hepatic overproduction of very-low-density lipoprotein [VLDL] cholesterol, the TG-rich lipoprotein*)
- Gout (*TG is frequently elevated in patients with gout, possibly related to alterations in apolipoprotein E genotypes*)
- Hyperlipoproteinemia (*related to increase in transport proteins*)
- Hypertension (*associated with elevated TG, which is identified*

as an independent risk factor in the development of CAD)

- Hypothyroidism (*significant relationship between elevated TG and decreased metabolism*)
- Impaired glucose tolerance (*increase in insulin stimulates production of TG by liver*)
- Metabolic syndrome (*syndrome consisting of obesity, high blood pressure, and insulin resistance*)
- Nephrotic syndrome (*related to absence or insufficient levels of lipoprotein lipase to remove circulating TG and to decreased catabolism of TG-rich VLDL lipoproteins*)
- Obesity (*significant and complex relationship between obesity and elevated TG*)
- Pancreatitis (*acute and chronic; related to effects on insulin production*)
- Pregnancy (*increased demand for production of hormones related to pregnancy*)
- Renal failure (*related to diabetes; elevated insulin levels stimulate production of TG by liver*)
- Respiratory distress syndrome (*related to artificial lung surfactant used for therapy*)
- Stress (*related to poor diet; effect of hormones secreted under stressful situations that affect glucose levels*)
- Syndrome X (*metabolic syndrome consisting of obesity, high blood pressure, and insulin resistance*)
- Werner's syndrome (*clinical features resemble syndrome X*)

Decreased in

- End-stage liver disease (*related to cessation of liver function that results in decreased production of TG and TG transport proteins*)
- Hyperthyroidism (*related to increased catabolism of VLDL transport proteins and general increase in metabolism*)

- Hypolipoproteinemia and abetalipoproteinemia (*related to decrease in transport proteins*)
- Intestinal lymphangiectasia
- Malabsorption disorders (*inadequate supply from dietary sources*)
- Malnutrition (*inadequate supply from dietary sources*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase triglyceride levels include acetylsalicylic acid, aldatense, atenolol, bisoprolol, β blockers, bendroflumethiazide, cholestyramine, conjugated estrogens, cyclosporine, estrogen/progestin therapy, estropipate, ethynodiol, etretinate, furosemide, glucocorticoids, hydrochlorothiazide, isotretinoin, labetalol, levonorgestrel, medroxyprogesterone, mepindolol, methylothiazide, metoprolol, miconazole, mirtazapine, nadolol, nafarelin, oral contraceptives, oxprenolol, pindolol, prazosin, propranolol, tamoxifen, thiazides, ticlopidine, timolol, and tretinoin.
- Drugs and substances that may decrease triglyceride levels include anabolic steroids, ascorbic acid, beclobrate, bezafibrate, captopril, carvedilol, celiprolol, celiprolol, chenodiol, cholestyramine, cilazapril, ciprofibrate, clofibrate, colestipol, danazol, dextrothyroxine, doxazosin, enalapril, eptastatin (type IIb only), fenofibrate, flaxseed oil, fluvastatin, gemfibrozil, halofenate, insulin, levonorgestrel, levothyroxine, lifibrol, lovastatin, medroxyprogesterone, metformin, nafenopin, niacin, niceritrol, Norplant, pentoxifylline, pinacidil, pindolol, pravastatin, prazosin, probucol, simvastatin, and verapamil.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Nutrition (<i>Related to excess caloric intake with large amounts of dietary sodium and fat; cultural lifestyle; overeating associated with anxiety, depression, compulsive disorder; genetics; inadequate or unhealthy food resources</i>)	Observable obesity; high fat or sodium food selections; high BMI; high consumption of ethnic foods; sedentary lifestyle; dietary religious beliefs and food selections; binge eating; diet high in refined sugar; repetitive dieting and failure	Discuss ideal body weight and the purpose and relationship between ideal weight and caloric intake to support cardiac health; review ways to decrease intake of saturated fats and increase intake of polyunsaturated fats; discuss limiting cholesterol intake to less than 300 mg per day; discuss limiting the intake of refined processed sugar; teach limiting sodium intake to the HCP's recommended restriction;

(table continues on page 1456)

Problem	Signs & Symptoms	Interventions
Health management <i>(Related to failure to regulate diet; lack of exercise; alcohol use; smoking)</i>	Inability or failure to recognize or process information toward improving health and preventing illness with associated mental and physical effects	encourage intake of fresh fruits and vegetables, unprocessed carbohydrates, poultry, and grains Encourage regular participation in weight-bearing exercise; assess diet, smoking, and alcohol use; teach the importance of adequate calcium intake with diet and supplements; refer to smoking cessation and alcohol treatment programs; collaborate with physician for bone density evaluation
Tissue perfusion <i>(Related to hypovolemia; decreased hemoglobin; interrupted arterial flow; interrupted venous flow)</i>	Hypotension; dizziness; cool extremities; pallor; capillary refill greater than 3 sec in fingers and toes; weak pedal pulses; altered level of consciousness; altered sensation	Monitor blood pressure; assess for dizziness; assess extremities for skin temperature, color, warmth; assess capillary refill; assess pedal pulses; monitor for numbness, tingling, hyperesthesia, hypoesthesia; monitor for DVT; instruct in careful use of heat and cold on affected areas; use foot cradle to keep pressure off of affected body parts
Fear <i>(Related to loss of control; ineffective coping; change in life expectancy; unfamiliar surroundings; illness; disease; unknown)</i>	Expression of fear; preoccupation with fear; increased tension; increased blood pressure; increased heart rate; vomiting; diarrhea; nausea; fatigue; weakness; insomnia;	Access social services; provide specific and culturally appropriate education; assist the patient and family to recognize effective coping strategies; assist the patient to acknowledge his or her fear; provide a safe environment to decrease fear; explore cultural influences that may enhance fear; utilize

Problem	Signs & Symptoms	Interventions
	shortness of breath; increased respiratory rate; withdrawal; panic attacks	therapeutic touch as appropriate to decrease fear; collaborate with social services, respiratory services, physical therapy, and occupational therapy to address specific medical problems associated with fear

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in monitoring and evaluating lipid levels.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for 12 hr before specimen collection; fasting is required prior to measurement of triglyceride levels. Ideally, the patient should be on a stable diet for 3 wk and avoid alcohol consumption for 3 days before specimen collection; alcohol increases triglyceride levels. Protocols may vary among facilities.
- ▶ Note that there are no medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions and other pre-testing preparations; assure that food has been restricted for at least 12 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, as directed by the HCP.

▶ **Nutritional Considerations:** Increased triglyceride levels may be associated with atherosclerosis and CAD. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Sensitivity to social and cultural issues:** Numerous studies point to the increased prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social,

and emotional consequences of excess body weight are significant. Special attention should be given to instructing the pediatric patient and caregiver regarding health risks and weight control.

- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services.
- ▶ Provide contact information, if desired, for the AHA (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient the negative effects that elevated triglycerides can have on cardiac health.
- ▶ Teach the patient to follow a diet of protein and complex carbohydrates.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that increased triglycerides can increase the risk of heart attack
- ▶ Compares traditionally ethnic foods to heart-healthy selections toward making dietary changes

Skills

- ▶ Exhibits proficiency in making dietary selections that are heart healthy
- ▶ Identifies strategies for effective coping that do not involve overeating

Attitude

- Discusses the correlation between selected diet and increased triglyceride levels
- Complies with HCP's recommended lifestyle changes to improve triglyceride levels

RELATED MONOGRAPHS:

- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, blood gases, BNP, calcium (total and ionized),

cholesterol (total, HDL, and LDL), CT cardiac scoring, C-reactive protein, CK and isoenzymes, echocardiography, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, myocardial infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, and troponin.

- Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Triiodothyronine, Free

SYNONYM/ACRONYM: Free T_3 , FT_3 .

COMMON USE: A complementary adjunct to evaluate thyroid hormone levels primarily related to hyperthyroidism and to assess causes of hypothyroidism.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units \times 0.0154)
0–3 days	2–7.9 pg/mL	0.03–0.12 pmol/L
4–30 days	2–5.2 pg/mL	0.03–0.08 pmol/L
1–23 mo	1.6–6.4 pg/mL	0.02–0.1 pmol/L
2–6 yr	2–6 pg/mL	0.03–0.09 pmol/L
7–17 yr	2.9–5.1 pg/mL	0.04–0.08 pmol/L
Adults and older adults	2.6–4.8 pg/mL	0.04–0.07 pmol/L
Pregnant women (4–9 mo gestation)	2–3.4 pg/mL	0.03–0.05 pmol/L

DESCRIPTION: Unlike the thyroid hormone thyroxine (T_4), most T_3 is converted enzymatically from T_4 in the tissues rather than being produced directly by the thyroid gland (see monograph titled “Thyroxine, Total”). Approximately one-third of T_4 is converted to T_3 .

Most T_3 in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free T_3 , which is the physiologically active form. Levels of free T_3 are proportional to levels of

total T_3 . The advantage of measuring free T_3 instead of total T_3 is that, unlike total T_3 measurements, free T_3 levels are not affected by fluctuations in TBG levels. T_3 is four to five times more biologically potent than T_4 . This hormone, along with T_4 , is responsible for maintaining a euthyroid state. Free T_3 measurements are rarely required, but they are indicated in the diagnosis of T_3 toxicosis and when certain drugs are being administered that interfere with the conversion of T_4 to T_3 .

This procedure is contraindicated for: N/A

INDICATIONS

- Adjunctive aid to thyroid-stimulating hormone (TSH) and free T_4 assessment
- Assist in the diagnosis of T_3 toxicosis

POTENTIAL DIAGNOSIS

Increased in

- High altitude
- Hyperthyroidism (*triiodothyronine is produced independently of stimulation by TSH*)
- T_3 toxicosis

Decreased in

- Hypothyroidism (*thyroid hormones are not produced in sufficient quantities regardless of TSH levels*)
- Malnutrition (*related to protein or iodine deficiency; iodine is needed for thyroid hormone synthesis and proteins are needed for transport*)
- Nonthyroidal chronic diseases
- Pregnancy (late)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase free T_3 include acetylsalicylic acid, amiodarone, and levothyroxine.
- Drugs that may decrease free T_3 include amiodarone, methimazole, phenytoin, propranolol, and radiographic agents.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing thyroid gland function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

- ▶ **Potential Complications:** N/A
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the

patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include albumin, antibodies antithyroglobulin, biopsy thyroid, copper, PTH, prealbumin, protein, RAIU, thyroglobulin, TBII, thyroid scan, TSH, TSI, T_4 , free T_4 , T_3 , and US thyroid.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Triiodothyronine, Total

SYNONYM/ACRONYM: T_3 .

COMMON USE: To assist in evaluating thyroid function primarily related to diagnosing hyperthyroidism and monitoring the effectiveness of therapeutic interventions.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 0.0154)
Cord blood	14–86 ng/dL	0.22–1.32 nmol/L
1–3 days	100–292 ng/dL	1.54–4.5 nmol/L
4–30 days	62–243 ng/dL	0.96–3.74 nmol/L
1–12 mo	105–245 ng/dL	1.62–3.77 nmol/L
1–5 yr	105–269 ng/dL	1.62–4.14 nmol/L
6–10 yr	94–241 ng/dL	1.45–3.71 nmol/L

(table continues on page 1462)

Age	Conventional Units	SI Units (Conventional Units × 0.0154)
16–20 yr	80–210 ng/dL	1.23–3.23 nmol/L
Adult	70–204 ng/dL	1.08–3.14 nmol/L
Older adult	40–181 ng/dL	0.62–2.79 nmol/L
Pregnant woman (last 4 mo gestation)	116–247 ng/dL	1.79–3.8 nmol/L

DESCRIPTION: Unlike the thyroid hormone thyroxine (T_4), most T_3 is converted enzymatically from T_4 in the tissues rather than being produced directly by the thyroid gland (see monograph titled “Thyroxine, Total”). Approximately one-third of T_4 is converted to T_3 . Most T_3 in the serum (99.97%) is bound to thyroxine-binding globulin (TBG), prealbumin, and albumin. The remainder (0.03%) circulates as unbound or free T_3 , which is the physiologically active form. Levels of free T_3 are proportional to levels of total T_3 . The advantage of measuring free T_3 instead of total T_3 is that, unlike total T_3 measurements, free T_3 levels are not affected by fluctuations in TBG levels. T_3 is four to five times more biologically potent than T_4 . This hormone, along with T_4 , is responsible for maintaining a euthyroid state.

This procedure is contraindicated for: N/A

INDICATIONS

Adjunctive aid to thyroid-stimulating hormone (TSH) and free T_4 assessment.

POTENTIAL DIAGNOSIS

Increased in

- Conditions with increased TBG (e.g., pregnancy and estrogen therapy)

- Early thyroid failure
- Hyperthyroidism (*triiodothyronine is produced independently of stimulation by TSH*)
- Iodine-deficiency goiter
- T_3 toxicosis
- Thyrotoxicosis factitia (*laboratory tests do not distinguish between endogenous and exogenous sources*)
- Treated hyperthyroidism

Decreased in

- Acute and subacute nonthyroidal disease (*pathophysiology is unclear*)
- Conditions with decreased TBG (*TBG is the major transport protein*)
- Hypothyroidism (*thyroid hormones are not produced in sufficient quantities regardless of TSH levels*)
- Malnutrition (*related to insufficient protein sources to form albumin and TBG*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase total T_3 levels include amiodarone, amphetamine, benziodarone, clofibrate, fluorouracil, halofenate, insulin, levothyroxine, methadone, opiates, oral contraceptives, phenothiazine, phenytoin, prostaglandins, and T_3 .
- Drugs that may decrease total T_3 levels include acetylsalicylic acid, amiodarone, anabolic steroids,

asparaginase, carbamazepine, cholestyramine, clomiphene, colestipol, dexamethasone, fenclofenac, furosemide, glucocorticoids, hydrocortisone, interferon alfa-2b, iobenzamic acid, iopanoic acid, ipodate, isotretinoin, lithium, methimazole, netilmicin, oral contraceptives, penicillamine, phenylbutazone, phenytoin, potassium iodide, prednisone, propranolol, propylthiouracil, radiographic agents, sodium ipodate, salicylate, sulfonyleureas, and tyropanoic acid.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing thyroid gland function.

Troponins I and T

SYNONYM/ACRONYM: Cardiac troponin, cardiac troponin I (cTnI), cardiac troponin T (cTnT).

COMMON USE: To assist in evaluating myocardial muscle damage related to disorders such as myocardial infarction.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable. Serial sampling is highly recommended. Care must be taken to use the same type of collection container if serial measurements are to be taken.

NORMAL FINDINGS: (Method: Enzyme immunoassay)

Troponin I	
0–30 d	Less than 4.8 ng/mL
1–3 mo	Less than 0.4 ng/mL
3–6 mo	Less than 0.3 ng/mL
7–12 mo	Less than 0.2 ng/mL
1–18 yr	Less than 0.1 ng/mL
Adult	Less than 0.05 ng/mL
Troponin T	
	Less than 0.2 ng/mL

Normal values can vary significantly due to differences in test kit reagents and instrumentation. The testing laboratory should be consulted for comparison of results to the corresponding reference range.

DESCRIPTION: Troponin is a complex of three contractile proteins that regulate the interaction of actin and myosin. Troponin C is the calcium-binding subunit; it

does not have a cardiac muscle-specific subunit. Troponin I and troponin T, however, do have cardiac muscle-specific subunits. They are detectable a few hours to 7 days after the onset of symptoms of myocardial damage. Troponin I is thought to be a more specific marker of cardiac damage than troponin T. Cardiac troponin I begins to rise 2 to 6 hr after myocardial infarction (MI). It has a biphasic peak: It initially peaks at 15 to 24 hr after MI and then exhibits a lower peak after 60 to 80 hr. Cardiac troponin T levels rise 2 to 6 hr after MI and remain elevated. Both proteins return to the reference range 7 days after MI.

Timing for Appearance and Resolution of Serum/ Plasma Cardiac Markers in Acute MI

Cardiac Marker	Appearance (hr)	Peak (hr)	Resolution (days)
AST	6–8	24–48	3–4
CK (total)	4–6	24	2–3
Cardiac Marker	Appearance (hr)	Peak (hr)	Resolution (days)
CK-MB	4–6	15–20	2–3

Timing for Appearance and Resolution of Serum/ Plasma Cardiac Markers in Acute MI

LDH	12	24–48	10–14
Myoglobin	1–3	4–12	1
Troponin I	2–6	15–20	5–7

AST = aspartate aminotransferase; CK = creatine kinase; CK-MB = creatine kinase MB fraction; LDH = lactate dehydrogenase.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in establishing a diagnosis of MI
- Evaluate myocardial cell damage

POTENTIAL DIAGNOSIS

Increased in

Conditions that result in cardiac tissue damage; troponin is released from damaged tissue into the circulation.

- Acute MI
- Minor myocardial damage
- Myocardial damage after coronary artery bypass graft surgery or percutaneous transluminal coronary angioplasty
- Unstable angina pectoris

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Cardiac output <i>(Prolonged myocardial ischemia; acute myocardial infarction; reduced cardiac muscle contractility; rupture papillary muscle; mitral insufficiency)</i>	Weak peripheral pulses; slow capillary refill; decreased urinary output; cool, clammy skin; tachypnea; dyspnea; altered level of consciousness; abnormal heart sounds; fatigue; hypoxia; loud holosystolic murmur; EKG changes; increased JVD	Assess peripheral pulses and capillary refill; monitor blood pressure and check for orthostatic changes; assess respiratory rate, breath sounds, and orthopnea; assess skin color and temperature; assess level of consciousness; monitor urinary output; use pulse oximetry to monitor oxygenation; monitor EKG; administer ordered inotropic and peripheral vasodilator medications, nitrates; provide oxygen administration

(table continues on page 1466)

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to myocardial ischemia; myocardial infarction</i>)	Reports of chest pain; new onset of angina; shortness of breath; pallor; weakness; diaphoresis; palpitations; nausea; vomiting; epigastric pain or discomfort; increased blood pressure; increased heart rate	Assess pain characteristics, squeezing pressure, location in substernal back neck or jaw; assess pain duration and onset (minimal exertion, sleep, or rest); identify pain modalities that have relieved pain in the past; monitor cardiac biomarkers (CK-MB, troponin, myoglobin); collaborate with ancillary departments to complete ordered echocardiography, exercise stress testing, pharmacological stress testing; administer prescribed pain medication; monitor and trend vital signs; administer prescribed oxygen; administer prescribed anticoagulants, anti-platelets, beta-blockers, calcium channel blockers, ACE inhibitors, ARBs, thrombolytic agents
Health management (<i>Related to failure to regulate diet; lack of exercise; alcohol use; smoking</i>)	Inability or failure to recognize or process information toward improving health and preventing illness with associated mental and physical effects	Collaborate with health-care provider (HCP) to develop a plan of care that supports cardiac health; assist patient to adhere to recommended medication regime; ensure patient attends a smoking cessation program; encourage patient to comply with health-care follow-up appointments; assess diet and lifestyle choices

Problem	Signs & Symptoms	Interventions
Fear (<i>Related to threat of MI, possible death; recurrent pain</i>)	Verbalization of fear; restlessness; increased tension; continuous questioning; increased blood pressure, heart rate, respiratory rate	Evaluate verbal and nonverbal indicators of fear; assess for the cause of fear; acknowledge the patient's awareness of his or her fear; explain all procedures with simple age-appropriate and culturally appropriate language; administer prescribed mild tranquilizer; maintain a confident, assured professional manner in all patient interactions

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating heart damage.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that a number of samples will be collected. Collection at time of admission, 2 to 4 hr, 6 to 8 hr, and 12 hr after admission are the minimal recommendations. Additional samples may be requested. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is

important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased troponin levels are associated with coronary artery disease (CAD). Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.
- ▶ **Social and Cultural Considerations:** Numerous studies point to the prevalence of excess body weight in American children and adolescents.

Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.

- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services.
- ▶ Provide contact information, if desired, for the AHA (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient and family to report chest pain as soon as it starts.
- ▶ Teach the patient about the disease progression and pathophysiology.

Expected Patient Outcomes:**Knowledge**

- ▶ States understanding of the signs and symptoms of heart attack
- ▶ States the purpose of prescribed medications to treat medical condition

Skills

- ▶ Identifies actions that can be taken to improve cardiac health, e.g., maintain a healthy diet, participate in regular physical activities, eliminate the use of tobacco products, and limit the use of alcohol, as appropriate.
- ▶ Identifies positive coping strategies that can be used to reduce fear.

Attitude

- Complies with the recommendation to undergo smoking cessation
- Complies with recommendations for lifestyle improvements to decrease the risk of future cardiac injury

RELATED MONOGRAPHS:

- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, blood pool imaging, BNP, calcium, ionized calcium, cholesterol (total, HDL, and LDL), CRP, CT cardiac scoring, CK and

isoenzymes, culture viral, echocardiography, echocardiography transesophageal, ECG, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, pericardial fluid analysis, PET heart, potassium, and triglycerides.

- Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Tuberculosis: Skin and Blood Tests

SYNONYM/ACRONYM: TST, TB tine test, PPD, Mantoux skin test, QuantiFERON-TB Gold blood test (QFT-G), QuantiFERON-TB Gold In-Tube test (QFT-GIT), T-SPOT.TB test (T-SPOT).

COMMON USE: To evaluate for current or past tuberculin infection or exposure.

SPECIMEN: Whole blood (5 mL) collected in a green-top (LiHep) tube (QuantiFERON-TB Gold and T-SPOT.TB blood tests), 1 mL whole blood collected in each of 3 special (Nil, Antigen and Mitogen) specimen containers (QuantiFERON-TB Gold In-Tube test).

NORMAL FINDINGS: (Method: Intradermal skin test, enzyme-linked immunosorbent assay [ELISA] blood test for QuantiFERON assays, enzyme-linked ImmunoSpot [ELISPOT] for T-SPOT.TB test) Negative.

DESCRIPTION: Routine screening for tuberculosis in the U.S. has not been needed for some time because until recently the disease had largely been eradicated. Recommendations for the timing of initial and subsequent screening may vary according to state laws, practitioners' guidelines, and specific circumstances (foreign adoptions or immigration from areas where tuberculosis is endemic, or in high risk environments such as healthcare or institutionalized settings). Children and adults are screened based on a risk

assessment. For example the America Academy of Pediatrics recommends identifying individuals at highest risk by means of a questionnaire before testing, while adults who either work or reside in a high risk environment are required to submit to annual Mantoux testing or chest x-ray (for individuals with a previously positive Mantoux test or individuals from other countries who have received the BCG vaccine). Tuberculin skin tests are done to determine past or present exposure to tuberculosis (TB). The

multipuncture or tine test is no longer used as a screening technique and has been largely replaced by the more definitive Mantoux test using Aplisol or Tubersol, purified protein derivatives of the mycobacterial cell wall, administered by intradermal injection. The Mantoux test is the test of choice in symptomatic patients. It is also used in some settings as a screening test. A negative result is judged if there is no sign of redness or induration at the site of the injection or if the zone of redness and induration is less than 5 mm in diameter. A positive result is evidenced by an area of erythema and induration at the injection site that is greater than 10 mm. A positive result does not distinguish between active and dormant infection. A positive response to the Mantoux test is followed up with chest radiography and bacteriological sputum testing to confirm diagnosis. The QuantiFERON-TB Gold (QFT-G), QuantiFERON-TB Gold In-Tube (QFT-GIT), and T-SPOT.TB interferon release blood tests are approved by the U.S. Food and Drug Administration for all applications in which the TB skin test is used. The blood tests are procedures in which T lymphocytes from the patient, either in whole blood or harvested from whole blood, are incubated with a reagent cocktail of peptides that simulate two or three proteins, ESAT-6, CFP-10, and TB7.7, made only by *Mycobacterium tuberculosis*. These proteins are not found in the blood of previously vaccinated individuals or individuals who do not have TB. The blood test offers the advantage of eliminating many of the false reactions encountered with skin testing, only a single patient visit is required, and results can be available within 24 hr.

Results obtained by the QFT-G test are not affected by BCG vaccination. The blood tests and skin tests are approved as indirect tests for *Mycobacterium tuberculosis*, and the Centers for Disease Control and Prevention (CDC) recommends their use in conjunction with risk assessment, chest x-ray and other appropriate medical and diagnostic evaluations.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate cough, weight loss, fatigue, hemoptysis, and abnormal x-rays to determine if the cause of symptoms is TB
- Evaluate known or suspected exposure to TB, with or without symptoms, to determine if TB is present
- Evaluate patients with medical conditions placing them at risk for TB (e.g., AIDS, lymphoma, diabetes)
- Screen populations at risk for developing TB (e.g., health-care providers [HCPs], nursing home residents, correctional facility personnel, prison inmates, and residents of the inner city living in poor hygienic conditions)

POTENTIAL DIAGNOSIS

Positive findings in

- Pulmonary TB

CRITICAL FINDINGS

- Positive results

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary

among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

General

- Each of the blood and skin tests evaluate different facets of the immune response and use different methodologies and reagents; interpretations may not be interchangeable.

Skin Test

- Drugs such as immunosuppressive agents or steroids can alter results.
- Diseases such as hematological cancers or sarcoidosis can alter results.
- Recent or present bacterial, fungal, or viral infections may affect results. False-positive results may be caused by the presence of non-tuberculous mycobacteria or by serial testing.
- False-negative results can occur if sensitized T cells are temporarily decreased. False-negative results also can occur in the presence of bacterial infections, immunological deficiencies, immunosuppressive agents, live-virus vaccinations (e.g., measles, mumps, varicella, rubella), malnutrition, old age, overwhelming TB, renal failure, and active viral infections (e.g., chickenpox, measles, mumps).

- Improper storage of the tuberculin solution (e.g., with respect to temperature, exposure to light, and stability on opening) may affect the results.
- Improper technique when performing the intradermal injection (e.g., injecting into subcutaneous tissue) may cause false-negative results.
- Incorrect amount or dilution of antigen injected or delayed injection after drawing the antigen up into the syringe may affect the results.
- Incorrect reading of the measurement of response or timing of the reading may interfere with results.
- It is not known whether the test has teratogenic effects or reproductive implications; the test should be administered to pregnant women only when clearly indicated.
- The test should not be administered to a patient with a previously positive tuberculin skin test because of the danger of severe reaction, including vesiculation, ulceration, and necrosis.
- The test does not distinguish between current and past infection.

Blood Test

- The performance of these blood tests has not been evaluated in large studies with patients who have impaired or altered immune function, have or are highly likely to develop TB, are younger than 17, are pregnant, or have diseases other than TB. These individuals are either immunosuppressed, immunocompromised, or have immature immune function and may not produce sufficient numbers of T lymphocytes for accurate results. The testing laboratory should be consulted for interpretation of results or limitations for use with patients in these categories.
- False-negative results are possible due to exposure or infection prior to development of detectable immune response.

- False-positive results are possible due to some cross-reactivity to some strains of environmental mycobacteria.
- False-negative results are possible due to exposure or infection prior to development of detectable immune response.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Breathing <i>(Related to productive cough; fatigue; inflammation)</i>	Tachypnea; dyspnea; orthopnea; change in the rate and depth of respirations; retractions; nasal flare; use of accessory muscles	Assess and trend respiratory rate and effort; monitor for retractions, nasal flare, and use of accessory muscles; evaluate cough effectiveness; auscultate lungs for adventitious breath sounds; monitor pulse oximetry and trend results; administer prescribed oxygen therapy; prepare for possible mechanical intubation; encourage oral fluids; encourage cough and deep breathing; pace activities
Infection <i>(Related to exposure to Mycobacterium tuberculosis)</i>	Productive cough of bloody sputum; fever with temperature spikes; positive AFB (acid fast bacillus) smear; fatigue; night sweats; weight loss; chills; lack of appetite	Send ordered sputum specimen for culture; monitor and trend temperature; monitor AFB smear results; induce sputum as ordered if patient is unable to provide one through cough; place in respiratory isolation (negative airflow); administer prescribed medications; instruct the patient to cover the mouth when coughing or sneezing; teach the patient to wash his or her hands after coming into contact with contaminated sputum; teach the patient and family the importance of wearing masks when visiting; report all confirmed TB cases to the Department of Health
Health maintenance <i>(Related to knowledge deficit; financial or cultural barriers; lack</i>	Inability or failure to recognize or process information toward improving health and preventing	Assess for evidence of therapeutic regime noncompliance (increased productive cough, drug-resistant culture results); identify the cause of noncompliance; arrange social services consult; teach the patient about the disease process and treatment modality in

Problem	Signs & Symptoms	Interventions
<i>of social support; no motivation; complexity of health-care system)</i>	illness with associated mental and physical effects; self-report of difficulty managing health regime; resistance to treatment; increased symptoms; chest x-ray confirmation of disease reactivation	understandable, culturally appropriate terms (transmission, symptoms, length of treatment, risk to others, follow-up appointments); consider referral of the continued noncompliant to a direct observation therapy program; explain the importance of taking prescribed medication; encourage smoking abstinence
Nutrition (<i>Related to poor appetite secondary to Mycobacterium tuberculosis infection</i>)	Unintended weight loss; pale dry skin; dry mucous membranes; documented inadequate caloric intake; subcutaneous tissue loss; hair pulls out easily; self-report of no appetite	Encourage a high-calorie, high-protein diet; encourage an increased intake of oral fluids; record accurate daily weight at the same time each day with the same scale; obtain an accurate nutritional history; assess attitude toward eating; promote a dietary consult to evaluate current eating habits and best method of nutritional supplementation; monitor nutritional laboratory values such as albumin; assess swallowing ability; encourage cultural home foods; provide a pleasant environment for eating; alter food seasoning to enhance flavor; provide parenteral or enteral nutrition as prescribed

PRETEST:**Blood and Skin Tests**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assess for a tuberculin infection or exposure.
- ▶ Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies and sensitivities to latex.

- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of TB or TB exposure, signs and symptoms indicating possible TB, and other skin tests or vaccinations and sensitivities.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient.

Skin Test

- ▶ Before beginning the test, ensure that the patient does not currently have TB and has not previously had a positive skin test. Do not administer the test if the patient has a skin rash or other eruptions at the test site. Inform the patient that the procedure takes approximately 5 min. Address concerns about pain and explain that a moderate amount of pain may be experienced when the intradermal injection is performed.
- ▶ Emphasize to the patient that the area should not be scratched or disturbed after the injection and before the reading.

Blood Test

- ▶ Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Blood and Skin Tests

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

Blood and Skin Tests

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

Skin Test

- ▶ Have epinephrine hydrochloride solution (1:1,000) available in the event of anaphylaxis.

- ▶ Cleanse the skin site on the lower anterior forearm with alcohol swabs and allow to air-dry.

Multipuncture Test

- ▶ Remove the cap covering the tines and stretch the forearm skin taut. Firmly press the device into the prepared site, hold it in place for 1 sec, and then remove it. Four punctures should be visible. Record the site, and remind the patient to return in 48 to 72 hr to have the test read. At the time of the reading, use a plastic ruler to measure the diameter of the largest indurated area, making sure the room is sufficiently lighted to perform the reading. A palpable induration greater than or equal to 2 mm at one or more of the punctures indicates a positive test result.

Mantoux (Intradermal) Test

- ▶ Prepare PPD or old tuberculin in a tuberculin syringe with a short, 26-gauge needle attached. Prepare the appropriate dilution and amount for the most commonly used intermediate strength (5 tuberculin units in 0.1 mL) or a first strength usually used for children (1 tuberculin unit in 0.1 mL). Inject the preparation intradermally at the prepared site as soon as it is drawn up into the syringe. When properly injected, a bleb or wheal 6 to 10 mm in diameter is formed within the layers of the skin. Record the site, and remind the patient to return in 48 to 72 hr to have the test read. At the time of the reading, use a plastic ruler to measure the diameter of the largest indurated area, making sure the room is sufficiently lighted to perform the reading. Palpate for thickening of the tissue; a positive result is indicated by a reaction of 5 mm or more with erythema and edema.

Blood Test

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop

bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Counsel the patient, as appropriate, regarding the risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen. Inform the patient that positive findings must be reported to local health department officials, who will question him or her regarding other persons who may have been exposed through contact. Educate the patient regarding access to counseling services.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Emphasize to the patient who receives skin testing the need to return and have the test results read within the specified time frame of 48 to 72 hr after injection.

- ▶ Inform the patient that the effects from a positive response at the site can remain for 1 wk.
- ▶ Educate the patient that a positive result may put him or her at risk for infection related to impaired primary defenses, impaired gas exchange related to decrease in effective lung surface, and intolerance to activity related to an imbalance between oxygen supply and demand.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding of the importance of covering the mouth during coughing or sneezing to decrease possibility of droplet contamination
- ▶ States understanding of the importance of an adequate fluid intake to liquefy secretions

Skills

- ▶ Demonstrates the correct technique for covering the mouth and nose when coughing or sneezing
- ▶ Demonstrates proficient cough and deep breathing

Attitude

- ▶ Complies with the request to refrain from smoking
- ▶ Complies with the recommendation to take prescribed medication as ordered

RELATED MONOGRAPHS:

- ▶ Related tests include alveolar/arterial gradient, angiography pulmonary, biopsy lung, blood gases, bronchoscopy, calcium, carbon dioxide, chest x-ray, CBC WBC count and differential, CT thoracic, culture and smear mycobacteria, culture blood, culture sputum, cytology sputum, eosinophil count, ESR, gallium scan, Gram stain, lung perfusion scan, lung ventilation scan, mediastinoscopy, pleural fluid analysis, PFT, and zinc.
- ▶ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Tuning Fork Tests

SYNONYM/ACRONYM: Bing test, Rinne test, Schwabach test, Weber test.

COMMON USE: To assess for and determine type of hearing loss.

AREA OF APPLICATION: Ears.

CONTRAST: N/A

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Normal findings in

- Normal air and bone conduction in both ears; no evidence of hearing loss
- Bing test: Pulsating sound that gets louder and softer when the opening to the ear canal is alternately opened and closed (*Note:* This result, observed in patients with normal hearing, is also observed in patients with sensorineural hearing loss.)
- Rinne test: Longer and louder tone heard by air conduction than by bone conduction (*Note:* This result, observed in patients with normal hearing, is also observed in patients with sensorineural hearing loss.)
- Schwabach test: Same tone loudness heard equally long by the examiner and the patient
- Weber test: Same tone loudness heard equally in both ears

Abnormal findings in

- Conduction hearing loss related to or evidenced by:
 - Impacted cerumen
 - Obstruction of external ear canal (*presence of a foreign body*)
 - Otitis externa (*infection in ear canal*)

Otitis media (*poor eustachian tube function or infection*)

Otitis media serous (*fluid in middle ear due to allergies or a cold*)

Otosclerosis

Bing test: No change in the loudness of the sound

Rinne test: Tone louder or detected for a longer time than the air-conducted tone

Schwabach test: Prolonged duration of tone when compared to that heard by the examiner

Weber test: Lateralization of tone to one ear, indicating loss of hearing on that side (i.e., tone is heard in the poorer ear)

- Sensorineural hearing loss related to or evidenced by:
 - Congenital damage or malformations of the inner ear
 - Ménière's disease
 - Ototoxic drugs (*aminoglycosides, e.g., gentamicin or tobramycin; salicylates, e.g., aspirin*)
 - Presbycusis (*gradual hearing loss experienced in advancing age*)
 - Serious infections (*meningitis, measles, mumps, other viral, syphilis*)
 - Trauma to the inner ear (*related to exposure to noise in excess of 90 dB or as a result of physical trauma*)
 - Tumor (*e.g., acoustic neuroma, cerebellopontine angle tumor, meningioma*)
 - Vascular disorders
- Bing test:* Pulsating sound that gets louder and softer when the opening to the ear canal is alternately opened and closed

Rinne test: Tone heard louder by air conduction

Schwabach test: Shortened duration of tone when compared to that heard by the examiner

Weber test: Lateralization of tone to one ear indicating loss of hearing on the other side (i.e., tone is heard in the better ear)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Ultrasound, Abdomen

SYNONYM/ACRONYM: Abdominal ultrasound, abdomen sonography.

COMMON USE: To visualize and assess the solid organs of the abdomen, including the aorta, bile ducts, gallbladder, kidneys, pancreas, spleen, and other large abdominal blood vessels. This study is used to perform biopsies and assist in diagnosing disorders such as aortic aneurysm, infections, fluid collections, masses, and obstructions. This procedure can also be used to evaluate therapeutic interventions such as organ transplants.

AREA OF APPLICATION: Abdomen from the xiphoid process to the umbilicus.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration (paracentesis). The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Abdominal US is valuable in determining aortic aneurysms, the internal components of organ masses (solid versus cystic), and for evaluating other abdominal diseases, ascites, and abdominal obstruction. Abdominal US can be performed on the same day as a radionuclide scan or other radiological procedure and is especially

valuable in patients who have hypersensitivity to contrast medium or are pregnant. US is also widely used for pediatric patients to help diagnose appendicitis and for infants to assign cause for recurrent vomiting.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine the patency and function of abdominal blood vessels, including the abdominal aorta; vena cava; and portal, splenic, renal, and superior and inferior mesenteric veins
- Detect and measure an abdominal aortic aneurysm
- Monitor abdominal aortic aneurysm expansion to prevent rupture
- Determine changes within small aortic aneurysms pre- and postsurgery
- Evaluate abdominal ascites
- Evaluate size, shape, and pathology of intra-abdominal organs

POTENTIAL DIAGNOSIS

Normal findings in

- Absence of ascites, aortic aneurysm, cysts, obstruction, or tumors
- Normal size, position, and shape of intra-abdominal organs and associated structures

Abnormal findings in

- Abdominal abscess, ascitic fluid, or hematoma
- Aortic aneurysm greater than 4 cm
- Congenital absence or malplacement of organs
- Gallbladder or renal calculi
- Tumor, liver, spleen, or retroperitoneal space

CRITICAL FINDINGS

- Aortic aneurysm measuring 5 cm or more in diameter.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Attenuation of the sound waves by the ribs, which can impair clear imaging of the upper abdominal structures
- Incorrect placement of the transducer over the desired test site; quality of the US study is very

dependent upon the skill of the ultrasonographer

- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Retained gas or barium from a previous radiological procedure

Other considerations

- Failure to follow dietary and fluid restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ Inform the patient this procedure can assist in assessing abdominal abnormalities.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of results of the patient's cardiovascular, gastrointestinal, genitourinary, and hepatobiliary systems, symptoms, and results of previously performed laboratory tests, diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hours between administration of barium and this test.
- ▶ Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that there may be moments of discomfort experienced during the test. Inform the patient that the procedure is performed in a ultrasound department, by a health-care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 minutes.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects in the area to be examined.
- ▶ Note that there are no food or fluid restrictions for US of the aorta. Restrictions for US studies of other abdominal organs may be imposed by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that food and fluids have been restricted, if required, prior to the procedure.
- ▶ Ensure that the patient has removed external metallic objects prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table. The right- or left-side-up positions may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- ▶ Expose the abdominal area and drape the patient.
- ▶ Conductive gel is applied to the skin, and a Doppler transducer is moved over the skin to obtain images of the area of interest.
- ▶ Ask the patient to breathe normally during the examination. If necessary for

better organ visualization, ask the patient to inhale deeply and hold his or her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be sent to the requesting HCP, who will discuss the results with the patient.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH and challenge tests, albumin, ALKP, ALT, amylase, angiography abdomen, AST, biopsy intestinal, biopsy liver, bilirubin and fractions, BUN, calcium, calculus kidney stone panel, cancer antigens, carbon dioxide, CBC, CBC hematocrit, CBC hemoglobin, CBC WBC and differential, chloride, cortisol and challenge tests, creatinine, CT abdomen, GGT, HCG, hepatobiliary scan, infectious mononucleosis, IVP, KUB, LDH, lipase, magnesium, MRI abdomen, peritoneal fluid analysis, phosphorus, potassium, PT/INR, renogram, sodium, US kidney, US liver and biliary, US pancreas, US spleen, uric acid, urinalysis, and WBC scan.
- ▶ Refer to the Cardiovascular, Gastrointestinal, Genitourinary, and Hepatobiliary systems tables at the end of the book for related tests by body system.

Ultrasound, Arterial Doppler, Carotid Studies

SYNONYM/ACRONYM: Carotid Doppler, carotid ultrasound, arterial ultrasound.

COMMON USE: To visualize and assess blood flow through the carotid arteries toward evaluating risk for stroke related to atherosclerosis.

AREA OF APPLICATION: Arteries.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor.

Using the duplex scanning method, carotid US records sound waves to obtain information about the carotid arteries. The amplitude and waveform of the carotid pulse are measured, resulting in a two-dimensional image of the artery. Carotid arterial sites used for the studies include the common carotid, external carotid, and internal carotid. Blood flow direction, velocity, and the presence of flow disturbances can be readily assessed. The sound waves that hit the moving red blood cells and are reflected back to the transducer correspond to the velocity of the blood flow through the vessel. The result is the visualization of the artery to assist in the diagnosis (i.e., presence, amount, location)

of plaque causing vessel stenosis or atherosclerotic occlusion affecting the flow of blood to the brain. Depending on the degree of stenosis causing a reduction in vessel diameter, additional testing can be performed to determine the effect of stenosis on the hemodynamic status of the artery.

The combined information obtained from carotid US and ankle-brachial index (ABI) provides significant support for predicting coronary artery disease. ABI is a noninvasive, simple comparison of blood pressure measurements in the arms and legs and can be used to detect peripheral artery disease (PAD). A Doppler stethoscope is used to obtain the systolic pressure in either the dorsalis pedis or the posterior tibial artery. This ankle pressure is then divided by the highest brachial systolic pressure acquired after taking the blood pressure in both of the patient's arms. This index should be greater than 1. When the index falls below 0.5, blood flow impairment is considered significant. Patients should be scheduled for a vascular consult for an abnormal ABI. Patients with diabetes or kidney disease, and some elderly patients, may have a falsely elevated ABI

due to calcifications of the vessels in the ankle causing an increased systolic pressure. The ABI test approaches 95% accuracy in detecting PAD. However, a normal ABI value does not absolutely rule out the possibility of PAD for some individuals, and additional tests should be done to evaluate symptoms.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of carotid artery occlusive disease, as evidenced by visualization of blood flow disruption
- Detect irregularities in the structure of the carotid arteries
- Detect plaque or stenosis of the carotid artery, as evidenced by turbulent blood flow or changes in Doppler signals indicating occlusion

POTENTIAL DIAGNOSIS

Normal findings in

- Normal blood flow through the carotid arteries with no evidence of occlusion or narrowing

Abnormal findings in

- Carotid artery occlusive disease (atherosclerosis)
- Plaque or stenosis of carotid artery
- Reduction in vessel diameter of more than 16%, indicating stenosis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Attenuation of the sound waves by bony structures, which can impair clear imaging of the vessels

- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the carotid arteries in the neck.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium or iodine-based contrast procedures, surgery, or biopsy). There should be 24 hr between administration of barium or iodine contrast medium and this test.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals. (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of

discomfort. Inform the patient that the procedure is performed in a US department by a health-care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table; other positions may be used during the examination.
- ▶ Expose the neck and drape the patient.
- ▶ Conductive gel is applied to the skin, and a Doppler transducer is moved over the skin to obtain images of the area of interest.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- ▶ When the study is completed, remove the gel from the skin.
- ▶ Instruct the patient to continue with diet, fluids, and medications, as directed by the HCP.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing coronary artery disease (CAD) or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated low-density lipoprotein [LDL] cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

Social and Cultural Considerations:

Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.

- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy and perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the AHA (www.americanheart.org), the NHLBI (www.nhlbi.nih.gov), or the Legs for Life (www.legsforlife.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy

regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography carotid, angiography coronary, antiarrhythmic drugs, apolipoprotein A & B, AST, blood gases, calcium, cholesterol (total, HDL, LDL), CT angiography, CT cardiac scoring, echocardiography, CRP, CK and isoenzymes, glucose, glycosylated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI angiography, MRI chest, MRI venography, myocardial infarction scan, myocardial perfusion heart scan, myoglobin, PET heart, triglycerides, troponin, US arterial Doppler upper and lower extremities, and US venous Doppler extremity.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Ultrasound, Arterial Doppler, Lower and Upper Extremity Studies

SYNONYM/ACRONYM: Doppler, arterial ultrasound, duplex scan.

COMMON USE: To visualize and assess blood flow through the arteries of the upper and lower extremities toward diagnosing disorders such as occlusion and aneurysm and evaluate for the presence of plaque and stenosis. This procedure can also be used to assess the effectiveness of therapeutic interventions such as arterial graphs and blood flow to transplanted organs.

AREA OF APPLICATION: Arteries of the lower and upper extremities.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. Using the duplex scanning method, arterial leg US records sound waves to obtain information about the arteries of the lower extremities from the common femoral arteries and their branches as they extend into the calf area. The amplitude and waveform of the pulses are measured, resulting in a two-dimensional image of the artery. Blood flow direction, velocity, and the presence of flow disturbances can be readily assessed, and for diagnostic studies, the technique is done bilaterally. The sound waves hit the moving red blood cells and are reflected back to the transducer corresponding to the velocity of the blood flow through the vessel. The result is the visualization of the artery to assist in the diagnosis (i.e., presence, amount, and location) of plaque causing vessel stenosis or occlusion and to help determine the cause of claudication. Arterial reconstruction and graft condition and patency can also be evaluated.

In arterial Doppler studies, arteriosclerotic disease of the peripheral vessels can be detected by slowly deflating blood pressure

cuffs that are placed on an extremity such as the calf, ankle, or upper extremity. The systolic pressure of the various arteries of the extremities can be measured. The Doppler transducer can detect the first sign of blood flow through the cuffed artery, even the most minimal blood flow, as evidenced by a swishing noise. There is normally a reduction in systolic blood pressure from the arteries of the arms to the arteries of the legs; a reduction exceeding 20 mm Hg is indicative of occlusive disease (deep vein thrombosis) proximal to the area being tested. This procedure may also be used to monitor the patency of a graft, status of previous corrective surgery, vascular status of the blood flow to a transplanted organ, blood flow to a mass, or the extent of vascular trauma.

The ankle-brachial index (ABI) can also be assessed during this study. This noninvasive, simple comparison of blood pressure measurements in the arms and legs can be used to detect peripheral artery disease (PAD). A Doppler stethoscope is used to obtain the systolic pressure in either the dorsalis pedis or the posterior tibial artery. This ankle pressure is then divided by the highest brachial systolic pressure acquired after taking the blood pressure in both of the patient's arms. This index should be greater than 1. When the index falls below 0.5, blood flow impairment is considered significant. Patients should be scheduled for a vascular consult for an abnormal ABI. Patients with diabetes or kidney disease, and some elderly patients, may have a falsely elevated ABI due to calcifications of the vessels

in the ankle causing an increased systolic pressure. The ABI test approaches 95% accuracy in detecting PAD. However, a normal ABI value does not absolutely rule out the possibility of PAD for some individuals, and additional tests should be done to evaluate symptoms.

This procedure is contraindicated for: N/A

INDICATIONS

- Aid in the diagnosis of small or large vessel PAD
- Aid in the diagnosis of spastic arterial disease, such as Raynaud's phenomenon
- Assist in the diagnosis of aneurysm, pseudoaneurysm, hematoma, arteriovenous malformation, or hemangioma
- Assist in the diagnosis of ischemia, arterial calcification, or plaques, as evidenced by visualization of blood flow disruption
- Detect irregularities in the structure of the arteries
- Detect plaque or stenosis of the lower extremity artery, as evidenced by turbulent blood flow or changes in Doppler signals indicating occlusion
- Determine the patency of a vascular graft, stent, or previous surgery
- Evaluate possible arterial trauma

POTENTIAL DIAGNOSIS

Normal findings in

- Normal blood flow through the lower extremity arteries with no evidence of vessel occlusion or narrowing
- Normal arterial systolic and diastolic Doppler signals
- Normal reduction in systolic blood pressure (i.e., less than

20 mm Hg) when compared to a normal extremity

- Normal ABI (greater than 0.85)

Abnormal findings in

- ABI less than 0.85, indicating significant arterial occlusive disease within the extremity
- Aneurysm
- Arterial calcification or plaques
- Embolic arterial occlusion
- Graft diameter reduction
- Hemangioma
- Hematoma
- Ischemia
- PAD
- Pseudoaneurysm
- Reduction in vessel diameter of more than 16%, indicating stenosis
- Spastic arterial occlusive disease, such as Raynaud's phenomenon

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Attenuation of the sound waves by bony structures, which can impair clear imaging of the vessels
- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations

- Cold extremities, resulting in vasoconstriction, which can cause inaccurate measurements
- Occlusion proximal to the site being studied, which would affect blood flow to the area

- Cigarette smoking, because nicotine can cause constriction of the peripheral vessels
- An abnormally large leg, making direct examination difficult

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing blood flow to the upper and lower extremities.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Report the presence of a lesion that is open or draining; maintain clean, dry dressing for the ulcer; protect the limb from trauma.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium or iodine-based contrast procedures, surgery, or biopsy). There should be 24 hr between administration of barium or iodine contrast medium and this test.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health-care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table; other positions may be used during the examination.
- ▶ Expose the area of interest and drape the patient.
- ▶ Place blood pressure cuffs on the thigh, calf, and ankle.
- ▶ Apply conductive gel to the skin over the area distal to each of the cuffs to promote the passage of sound waves as a Doppler transducer is moved over the skin to obtain images of the area of interest.
- ▶ Inflate the thigh cuff to a level above the patient's systolic pressure found in the normal extremity.
- ▶ Place the Doppler transducer in the gel, distal to the inflated cuff, and slowly release the pressure in the cuff.
- ▶ When the swishing sound of blood flow is heard, record it at the highest point along the artery at which it is audible. The test is repeated at the calf and then the ankle.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Instruct the patient to continue diet, fluids, and medications, as directed by the HCP.
- ▶ **Nutritional Considerations:** Nutritional therapy is recommended for the patient identified to be at risk for developing coronary artery disease (CAD) or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation of moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high

- in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. Patients on low-sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the American Heart Association (www.americanheart.org), the National Heart, Lung, and Blood Institute (www.nhlbi.nih.gov), or the Legs for Life (www.legsforlife.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include alveolar/arterial ratio, ANA, angiography pulmonary, aPTT, blood gases, CBC platelet count, CT angiography, D-Dimer, FDP, fibrinogen, lung perfusion scan, lung ventilation scan, MRI abdomen, MRI angiography, plethysmography, PT/INR, US venous Doppler lower extremities, and venography lower extremity.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Ultrasound, A-scan

SYNONYM/ACRONYM: Amplitude modulation scan, A-scan ultrasound biometry.

COMMON USE: To assess for ocular tissue abnormality related to lens replacement in cataract surgery.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: Diagnostic techniques such as A-scan ultrasonography can be used to identify abnormal tissue. The A-scan employs a single-beam, linear sound wave to detect abnormalities by returning an echo when interference disrupts its straight path. When the sound wave is directed at lens vitreous, the normal homogeneous tissue does not return an echo; an opaque lens with a cataract will produce an echo. The returning waves produced by abnormal tissue are received by a microfilm that converts the sound energy into electrical impulses that are amplified and displayed on an oscilloscope as an ultrasonogram or echogram. The A-scan echo can be used to indicate the position of the cornea and retina. The A-scan is most commonly used to measure the axial length of the eye. This measurement is used to determine the power requirement for an intraocular lens used to replace the abnormal, opaque lens of the eye removed in cataract surgery. There are two different methods currently in use. The applanation method involves placement of an ultrasound (US) probe directly on the cornea. The immersion technique is more popular because it

does not require direct contact and compression of the cornea. The immersion technique protects the cornea by placement of a fluid layer between the eye and the US probe. The accuracy of the immersion technique is thought to be greater than applanation because no corneal compression is caused by the immersion method. Therefore, the measured axial length achieved by immersion is closer to the true axial length of the cornea.

This procedure is contraindicated for: N/A

INDICATIONS

- Determination of power requirement for replacement intraocular lens in cataract surgery.

POTENTIAL DIAGNOSIS

Normal findings in

- Normal homogeneous ocular tissue

Abnormal findings in

- Cataract

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate and remain still during the

procedure may interfere with the test results.

- Rubbing or squeezing the eyes may affect results.
- Improper placement of the probe tip to the surface of the eye may produce inaccurate results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure determines the strength of the lens that will be replaced during cataract surgery.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially topical anesthetic eyedrops.
- ▶ Obtain a history of the patient's known or suspected vision loss; changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- ▶ Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- ▶ Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain and explain that no discomfort will be experienced during the test but that some discomfort may be experienced after the test when the numbness

wears off from the anesthetic drops administered prior to the test. Inform the patient that a health-care provider (HCP) performs the test in a quiet, darkened room and that evaluation of the eye upon which surgery is to be performed can take up to 10 min.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instill topical anesthetic in each eye, as ordered, and provide time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (gray, semi-transparent area of the eyeball where the cornea and sclera meet). Neither the dropper nor the bottle should touch the eyelashes.
- ▶ Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. When the US probe is properly positioned on the patient's surgical eye, a reading is automatically taken.
- ▶ Multiple measurements may be taken in order to ensure that a consistent and accurate reading has been achieved. Variability between serial measurements is unavoidable using the applanation technique.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss, anticipated loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of test results on the patient's lifestyle. Reassure the patient regarding concerns related to the impending cataract surgery. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing,

treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include refraction and slit-lamp biomicroscopy.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Ultrasound, Biophysical Profile, Obstetric

SYNONYM/ACRONYM: BPP ultrasound, fetal age sonogram, gestational age sonogram, OB sonography, pregnancy ultrasound, pregnancy echo, pregnant uterus ultrasonography.

COMMON USE: To visualize and assess the fetus in utero to monitor fetal health related to growth, congenital abnormalities, distress, and demise. Also used to identify gender and multiple pregnancy and to obtain amniotic fluid for analysis.

AREA OF APPLICATION: Pelvis and abdominal region.

CONTRAST: N/A.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical

energy, amplified by the transducer, and displayed as images on a monitor to visualize the fetus and placenta. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration (amniocentesis). The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs. This procedure is done by a transabdominal

or transvaginal approach, depending on when the procedure is performed (first trimester [transabdominal or transvaginal or combination] vs. second or third trimester [transabdominal]). It is the safest method of examination to evaluate the uterus and determine fetal size, growth, and position; fetal structural abnormalities; ectopic pregnancy; placenta position and amount of amniotic fluid; and multiple gestation.

Obstetric US is used to secure different types of information regarding the fetus and placenta, varying with the trimester during which the procedure is done. This procedure may also include a non-stress test (NST) in combination with Doppler monitoring of amniotic fluid volume, fetal heart, gross fetal movements, fetal muscle tone, and fetal respiratory movements to detect high-risk pregnancy. The procedure is indicated as a

guide for amniocentesis, cordocentesis, fetoscopy, aspiration of multiple oocytes for in vitro fertilization, and other intrauterine interventional procedures.

The biophysical profile (BPP) considers five antepartum parameters measured to predict fetal wellness. The BPP is indicated in women with high-risk pregnancies to identify a fetus in distress or in jeopardy of demise. It includes fetal heart rate (FHR) measurement, fetal breathing movements, fetal body movements, fetal muscle tone, and amniotic fluid volume. Each of the five parameters is assigned a score of either 0 or 2, allowing a maximum or perfect score of 10. The NST is an external US monitoring of FHR performed either as part of the BPP or when one or more of the US procedures have abnormal results. The NST is interpreted as either reactive or nonreactive.

BPP

Parameter	Normal: Score = 2	Abnormal: Score = 0
Fetal heart rate reactivity	Two or more movement-associated FHR accelerations of 15 or more beats/min above baseline, lasting 15 sec, in a 20-min interval	One or no movement-associated FHR accelerations of 15 or more beats/min above baseline in a 20-min interval
Fetal breathing movements	One or more breathing movements lasting 20–60 sec in a 30-min interval	Absent or no breathing movements lasting longer than 19 sec in a 30-min interval
Fetal body movements	Two or more discrete body or limb movements in a 30-min interval	Less than two discrete body or limb movements in a 30-min interval
Fetal muscle tone	One or more episodes of active limb extension and return to flexion (to include opening and closing of hand)	Absent movement, slow extension with partial return to flexion, partial opening of hand
Amniotic fluid volume	One or more pockets of fluid that are 2 cm or more in the vertical axis	No pockets of fluid or no pocket measuring at least 2 cm in the vertical axis

A contraction stress test (CST or oxytocin challenge test) may be requested in the event of an abnormal fetal heart rate in the BPP or NST. The CST is used to assess the fetus's ability to tolerate low oxygen levels as experienced during labor contractions. The CST includes external FHR monitoring by US and measurement of oxytocin (Pitocin)-induced uterine contractions. Pressure changes during contractions are monitored on an external tocodynamometer. Results of the two tests are interpreted as negative or positive. A negative or normal finding is no late decelerations of FHR during three induced contractions over a 10-min period. A positive or abnormal finding is identified when frequent contractions of 90 sec or more occur and FHR decelerates beyond the time of the contractions. The amniotic fluid index (AFI) is another application of US used to estimate amniotic fluid volume. The abdomen is divided into four quadrants using the umbilicus to delineate upper and lower halves and linea nigra to delineate the left and right halves. The numbered score is determined by adding the sum in centimeters of fluid in pockets seen in each of the four quadrants. The score is interpreted in relation to gestational age. The median index is considered normal between 8 and 12 cm. Oligohydramnios (too little amniotic fluid) is associated with an index between 5 and 6 cm, and polyhydramnios (too much amniotic fluid) with an index between 18 and 22 cm.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect blighted ovum (missed abortion), as evidenced by empty gestational sac
- Detect fetal death, as evidenced by absence of movement and fetal heart tones
- Detect fetal position before birth, such as breech or transverse presentations
- Detect tubal and other forms of ectopic pregnancy
- Determine and confirm pregnancy or multiple gestation by determining the number of gestational sacs in the first trimester
- Determine cause of bleeding, such as placenta previa or abruptio placentae
- Determine fetal effects of Rh incompatibility due to maternal sensitization
- Determine fetal gestational age by uterine size and measurements of crown-rump length, biparietal diameter, fetal extremities, head, and other parts of the anatomy at key phases of fetal development
- Determine fetal heart and body movements and detect high-risk pregnancy by monitoring fetal heart and respiratory movements in combination with Doppler US or real-time grayscale scanning
- Determine fetal structural anomalies, usually at the 20th week of gestation or later
- Determine the placental size, location, and site of implantation
- Differentiate a tumor (hydatidiform mole) from a normal pregnancy
- Guide the needle during amniocentesis and fetal transfusion
- Measure fetal gestational age and evaluate umbilical artery, uterine artery, and fetal aorta by Doppler examination to determine fetal intrauterine growth retardation

- Monitor placental growth and amniotic fluid volume

POTENTIAL DIAGNOSIS

Normal findings in

- Normal age, size, viability, position, and functional capacities of the fetus
- Normal placenta size, position, and structure; adequate volume of amniotic fluid
- BPP score of 8 to 10 is considered normal. Each of the fetal movements evaluated in the BPP is related to oxygen-dependent activities that originate from the central nervous system. Their presence is assumed to indicate normal brain function and absence of systemic hypoxia.

Abnormal findings in

- Abruptio placentae
- Cardiac abnormalities
- Ectopic pregnancy
- Fetal death
- Fetal deformities (organs or skeleton)
- Fetal hydros (non-immune)
- Fetal intestinal atresia
- Fetal malpresentation (breech, transverse)
- Hydrocephalus
- Myelomeningocele
- Multiple pregnancy
- Placenta previa
- Renal or skeletal defects
- BPP score between 4 and 6 is considered equivocal. Gestational age is important in determining intervals for retesting and/or a decision to deliver.

CRITICAL FINDINGS

- Abruptio placentae
- BPP score between 0 and 2 is abnormal and indicates the need for assessment and immediate delivery.
- Ectopic pregnancy
- Fetal death
- Placenta previa

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Patients with latex allergy; use of the vaginal probe requires the probe to be covered with a condom-like sac, usually made from latex. Latex-free covers are available.

Factors that may impair clear imaging

- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

- Retained gas or barium from a previous radiological procedure
- Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging

Factors that may result in incorrect values

- Absence of activity in a particular parameter of the BPP may be related to fetal sleep pattern; gestational age less than 33 wk or greater than 42 wk; maternal ingestion of glucose, nicotine, or alcohol; maternal administration of magnesium or medications; artificial or premature rupture of membranes; and/or labor.

Other considerations

- Patients who are very obese, who may exceed the weight limit for the equipment.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assess abdomen and pelvic organ function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- ▶ Endoscopic retrograde cholangiopancreatography and colonoscopy, if ordered, should be scheduled after this procedure.
- ▶ Record the date of the last menstrual period. Obtain a history of menstrual dates, previous pregnancy, and treatment received for high-risk pregnancy.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient the procedure is performed in a US department, usually by an HCP specializing in this procedure, and takes approximately 30 to 60 min.
- ▶ For the transvaginal approach, inform the patient that a sterile latex- or sheath-covered probe will be inserted into the vagina.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient receiving transabdominal US to drink three to four glasses of fluid 90 min before the procedure, and not to void, because the procedure requires a full bladder. Patients receiving transvaginal US only do not need to have a full bladder.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food or medication restrictions unless by medical direction. The test may be scheduled in relation to mealtime because fetal activity is highest 1 to 3 hr after the mother ingests a meal.

INTRATEST:**Potential Complications:** N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Ensure that the patient receiving transabdominal US drank three to four glasses of fluid and has not voided.
- ▶ Instruct the patient to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Place the patient in the supine position on an examination table. The right- or left-side-up position may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- ▶ Expose the abdominal area and drape the patient.
- ▶ **Transabdominal approach:** Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest.
- ▶ **Transvaginal approach:** A lubricated, covered probe is inserted into the vagina and moved to different levels to obtain images.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Allow the patient to void, as needed.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Recognize anxiety related to test results. Discuss the implications of

abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Encourage the family to seek appropriate counseling if concerned with pregnancy termination and to seek genetic counseling if a chromosomal abnormality is determined. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant and for exploring other options (termination of pregnancy or adoption). It is also important to discuss problems the mother and father may experience (guilt, depression, anger) if fetal abnormalities are detected.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. There are numerous tests for fetal genetic testing associated with inherited diseases and congenital abnormalities. The tests can be performed from amniotic fluid by methods that include polymerase chain reaction, microarray, and cell culture with karyotyping comparison. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include amniotic fluid analysis and L/S ratio, biopsy chorionic villus, blood groups and antibodies, chromosome analysis, culture bacterial anal/genital, culture viral, fetal fibronectin, α_1 -fetoprotein, hexosaminidase A and B, human chorionic gonadotropin, KUB, Kleihauer-Betke test, MRI abdomen, and prolactin.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Ultrasound, Bladder

SYNONYM/ACRONYM: Bladder sonography.

COMMON USE: To visualize and assess the bladder toward diagnosing disorders such as retention, obstruction, distention, cancer, infection, bleeding, and inflammation.

AREA OF APPLICATION: Bladder.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Bladder US evaluates the structure and position of the contents of the bladder and identifies disorders of the bladder, such as masses or lesions. The methods for imaging may include the transrectal, transurethral, and transvaginal approaches. The examination is helpful for monitoring a patient's response to therapy for bladder disease. Bladder images

can be included in other US studies such as the kidneys, ureters, bladder, urethra, and gonads in diagnosing renal/neurological disorders.

The bladder scan is another noninvasive US study commonly used to assess post-void residual. Advantages of the bladder scan over other studies, such as cystometry, is that the study can be performed at the bedside and does not require the patient to be catheterized, thereby eliminating the possibility of the patient developing a catheter-related UTI. The patient's gynecological history should be obtained prior to using the scanner in order to select the proper setting. The scanners have settings for male, female, and child, but scanning a female patient who has had a hysterectomy and is without a uterus should be performed using the settings for a male patient. This test is not usually performed on pregnant women. Normal findings are less than 50 mL. Report a residual urine that is greater than 100 mL or as directed by the requesting HCP.

This procedure is contraindicated for: N/A

INDICATIONS

- Assess residual urine after voiding to diagnose urinary tract obstruction causing overdistention
- Detect tumor of the bladder wall or pelvis, as evidenced by distorted position or changes in bladder contour
- Determine end-stage malignancy of the bladder caused by extension of a primary tumor of the ovary or other pelvic organ
- Evaluate the cause of urinary tract infection, urine retention, and flank pain
- Evaluate hematuria, urinary frequency, dysuria, and suprapubic pain
- Measure urinary bladder volume by transurethral or transvaginal approach

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and contour of the bladder

Abnormal findings in

- Bladder diverticulum
- Cyst
- Cystitis
- Malignancy of the bladder
- Tumor
- Ureterocele
- Urinary tract obstruction

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Patients with latex allergy; use of the vaginal probe requires the probe to be covered with a condom-like sac, usually made from latex. Latex-free covers are available.

Factors that may impair clear imaging

- Incorrect placement of the transducer over the desired test site; quality of the US study is very

dependent upon the skill of the ultrasonographer

- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Retained gas or barium from a previous radiological procedure
- Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging

Other considerations

- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the bladder and pelvic organs.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.

- ▶ Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health-care provider (HCP), with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Inform the patient for the transvaginal approach, that a sterile latex- or sheath-covered probe will be inserted into the vagina.
- ▶ Instruct the patient receiving transabdominal US to drink three to four glasses of fluid 90 min before the procedure, and not to void, because the procedure requires a full bladder. Patients receiving transvaginal US only do not need to have a full bladder.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
 - ▶ Ensure that the patient receiving transabdominal US drank three to four glasses of fluid and has not voided.
 - ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Instruct the patient to change into the gown, robe, and foot coverings provided.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
 - ▶ Place the patient in the supine position on an examination table. The right- or left-side-up positions may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
 - ▶ Expose the abdominal area and drape the patient.
 - ▶ **Transabdominal approach:**
Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest.
 - ▶ **Transvaginal approach:** A covered and lubricated probe is inserted into the vagina and moved to different levels during scanning.
 - ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
 - ▶ Instruct the patient who is to be examined for residual urine volume to empty the bladder; repeat the procedure and calculate the volume.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Allow the patient to void, as needed.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include bladder cancer markers urine, CT pelvis, cystoscopy, IVP, KUB study, and MRI pelvis.
- Refer to the Genitourinary System table in the end of the book for related tests by body system.

Ultrasound, Breast

SYNONYM/ACRONYM: Mammographic ultrasound.

COMMON USE: Used in place of or in conjunction with mammography to assist in diagnosing disorders such as tumor, cancer, and cysts.

AREA OF APPLICATION: Breast.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

When used in conjunction with mammography and clinical

examination, breast US is indispensable in the diagnosis and management of benign and malignant processes. Both breasts are usually examined during this procedure. Images displayed on a monitor can determine the presence of palpable and nonpalpable masses; size and structure of the mass can also be evaluated. This procedure is useful in patients with an abnormal mass on a mammogram, because it can determine whether the abnormality is cystic or solid; that is, it can differentiate between a palpable, fluid-filled cyst and a palpable, solid breast lesion (benign or malignant). It is especially useful in patients with dense breast tissue and in those with silicone prostheses, because the US beam easily penetrates in these situations, allowing routine examination that cannot be performed with x-ray mammography.

The procedure can be done as an adjunct to mammography, or it can be done in place of mammography in patients who refuse x-ray exposure or in whom it is contraindicated (e.g., pregnant women, women less than 25 yr *related to increased breast tissue density that produces unclear images*).

This procedure is contraindicated for: N/A

INDICATIONS

- Detect very small tumors in combination with mammography for diagnostic validation
- Determine the presence of nonpalpable abnormalities viewed on mammography of dense breast tissue and monitor changes in these abnormalities
- Differentiate among types of breast masses (e.g., cyst, solid tumor, other lesions) in dense breast tissue
- Evaluate palpable masses in young (less than age 25), pregnant, and lactating patients
- Guide interventional procedures such as cyst aspiration, large-needle core biopsy, fine-needle aspiration biopsy, abscess drainage, presurgical localization, and galactography
- Identify an abscess in a patient with mastitis

POTENTIAL DIAGNOSIS

Normal findings in

- Normal subcutaneous, mammary, and retromammary layers of tissue in both breasts; no evidence of pathological lesions (cyst or tumor) in either breast

Abnormal findings in

- Abscess
- Breast solid tumor, lesions
- Cancer (ductal carcinoma, infiltrating lobular carcinoma, medullary

- carcinoma, tubular carcinoma, and papillary carcinoma)
- Cystic breast disease
- Fibroadenoma
- Focal fibrosis
- Galactocele
- Hamartoma (fibroadenolipoma)
- Hematoma
- Papilloma
- Phyllodes tumor
- Radial scar

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Excessively large breasts
- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the breast.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health-care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient not to apply lotions, deodorant, bath powder, or other substances to the chest and breast area before the examination.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has not applied lotions, deodorant, bath powder, or other substances to the chest and breast area before the examination.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to change into the gown and robe provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table. The right- and left-side-up positions are also used

during the scan to facilitate better organ visualization.

- ▶ Expose the breast area and drape the patient.
- ▶ Conductive gel is applied to the skin and a transducer is moved over the skin to obtain images of the area of interest.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Society (www.cancer.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of breast self-examination, mammography, magnetic resonance imaging (MRI) of the breast, or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society (ACS) recommends breast examinations be performed every 3 yr for women between the ages of 20 and 39 yr and annually for women over 40 yr of age; annual mammograms should be performed on women 40 yr and older as long as they are in good health. The ACS also recommends annual MRI testing for women at high risk of developing breast cancer. Genetic testing for inherited mutations (BRCA1 and BRCA2) associated with increased risk of developing breast cancer may be ordered for women at risk. The test is performed on a blood

specimen. The most current guidelines for breast cancer screening of the general population as well as of individuals with increased risk are available from the ACS (www.cancer.org), the American College of Obstetricians and Gynecologists (ACOG) (www.acog.org), and the American College of Radiology (www.acr.org). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor

progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy breast, cancer antigens, chest x-ray, CT thorax, ductography, mammogram, MRI breast, and stereotactic biopsy breast.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Ultrasound, Kidney

SYNONYM/ACRONYM: Renal ultrasound, renal sonography.

COMMON USE: To visualize and assess the kidneys, to perform biopsies, and assist in diagnosing disorders such as tumor, cancer, stones, and congenital anomalies. This procedure can also be used to evaluate therapeutic interventions such as transplants.

AREA OF APPLICATION: Kidney.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic

tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Renal US is used to evaluate the structure, size, and position of the kidneys and to identify renal system disorders. It is valuable for determining the internal components of renal masses (solid versus cystic) and for evaluating other renal diseases, renal parenchyma, perirenal tissues, and obstruction. Renal US can be performed on the

same day as a radionuclide scan or other radiological procedure and is especially valuable in patients who are in renal failure, have hypersensitivity to contrast medium, have a kidney that did not visualize on IV pyelography (IVP), or are pregnant. It does not rely on renal function or the injection of contrast medium to obtain a diagnosis. The procedure is indicated for evaluation after a kidney transplant and is used as a guide for biopsy and other interventional procedures, abscess drainage, and nephrostomy tube placement. Renal US may be the diagnostic examination of choice because no radiation is used and, in most cases, the accuracy is sufficient to make the diagnosis without further imaging procedures.

This procedure is contraindicated for: N/A

INDICATIONS

- Aid in the diagnosis of the effect of chronic glomerulonephritis and end-stage chronic renal failure on the kidneys (e.g., decrease in size)
- Detect an accumulation of fluid in the kidney caused by backflow of urine, hemorrhage, or perirenal fluid
- Detect masses and differentiate between cysts or solid tumors, as evidenced by specific waveform patterns or absence of sound waves
- Determine the presence and location of renal or ureteral calculi and obstruction
- Determine the size, shape, and position of a nonfunctioning kidney to identify the cause
- Evaluate or plan therapy for renal tumors
- Evaluate renal transplantation for changes in kidney size
- Locate the site of and guide percutaneous renal biopsy, aspiration

needle insertion, or nephrostomy tube insertion

- Monitor kidney development in children when renal disease has been diagnosed
- Provide the location and size of renal masses in patients who are unable to undergo IVP because of poor renal function or an allergy to iodinated contrast medium

POTENTIAL DIAGNOSIS

Normal findings in

- Absence of calculi, cysts, hydronephrosis, obstruction, or tumor
- Normal size, position, and shape of the kidneys and associated structures

Abnormal findings in

- Acute glomerulonephritis
- Acute pyelonephritis
- Congenital anomalies, such as absent, horseshoe, ectopic, or duplicated kidney
- Hydronephrosis
- Obstruction of ureters
- Perirenal abscess or hematoma
- Polycystic kidney
- Rejection of renal transplant
- Renal calculi
- Renal cysts, hypertrophy, or tumors
- Ureteral obstruction

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Attenuation of the sound waves by the ribs, which can impair clear imaging of the kidney
- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images

- **Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status**

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing kidney function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- ▶ Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure. Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department, usually by a health-care provider (HCP), with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table. The right- or left-side-up positions may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- ▶ Expose the abdominal and kidney area and drape the patient.
- ▶ Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography renal, anti-glomerular basement membrane antibody, biopsy kidney, BUN, calculus kidney stone panel, CT abdomen, creatinine, creatinine clearance, cytology urine, erythropoietin, group A streptococcal screen, IVP, KUB study, MRI abdomen, renogram, retrograde ureteropyelography, UA, and US abdomen.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by system.

Ultrasound, Liver and Biliary System

SYNONYM/ACRONYM: Gallbladder ultrasound, liver ultrasound, hepatobiliary sonography.

COMMON USE: To visualize and assess liver and gallbladder structure and function, assist in obtaining a biopsy, and diagnose disorders such as gallstones, cancer, tumors, cysts, and bleeding. Also used to evaluate the effectiveness of therapeutic interventions.

AREA OF APPLICATION: Liver, gallbladder, bile ducts.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies,

tube placement, and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Hepatobiliary US is used to evaluate the structure, size, and position of the liver and gallbladder in the right upper quadrant (RUQ) of the abdomen. The gallbladder and biliary system collect, store, concentrate, and transport bile to the intestines to aid in digestion. This procedure allows visualization of the gallbladder and bile ducts when the patient may have impaired liver function, and it is especially helpful when done on patients in whom gallstones

cannot be visualized with oral or IV radiological studies. Liver US can be done in combination with a nuclear scan to obtain information about liver function and density differences in the liver.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect cysts, polyps, hematoma, abscesses, hemangioma, adenoma, metastatic disease, hepatitis, or solid tumor of the liver or gallbladder, as evidenced by echoes specific to tissue density and sharply or poorly defined masses
- Detect gallstones or inflammation when oral cholecystography is inconclusive
- Detect hepatic lesions, as evidenced by density differences and echo-pattern changes
- Determine the cause of unexplained hepatomegaly and abnormal liver function tests
- Determine cause of unexplained RUQ pain
- Determine patency and diameter of the hepatic duct for dilation or obstruction
- Differentiate between obstructive and nonobstructive jaundice by determining the cause
- Evaluate response to therapy for tumor, as evidenced by a decrease in size of the organ
- Guide biopsy or tube placement
- Guide catheter placement into the gallbladder for stone dissolution and gallbladder fragmentation

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of the liver and gallbladder as well as

patency of the cystic and common bile ducts

Abnormal findings in

- Biliary or hepatic duct obstruction/dilation
- Cirrhosis
- Gallbladder inflammation, stones, carcinoma, polyps
- Hematoma or trauma
- Hepatic tumors, metastasis, cysts, hemangioma, hepatitis
- Hepatocellular disease, adenoma
- Hepatomegaly
- Intrahepatic abscess
- Subphrenic abscesses

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Attenuation of the sound waves by bony structures, which can impair clear imaging of the right lobe of the liver
- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure

Other considerations

- Failure to follow dietary restrictions may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing liver and biliary function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- ▶ Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department, usually by a health-care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that food and fluids have been restricted for at least 8 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table. The right- or left-side-up positions may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- ▶ Expose the abdominal area and drape the patient.
- ▶ Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALP, ALT, AST, bilirubin, biopsy liver, cholangiography, colonoscopy, CT abdomen, endoscopy, ERCP, GGT, haptoglobin, hepatitis (A, B, C antigens and/or antibodies), hepatobiliary scan, laparoscopy abdominal, MRI abdomen, radiofrequency ablation liver, and US abdomen.
- ▶ Refer to the Hepatobiliary System table at the end of the book for related tests by body system.

Ultrasound, Lymph Nodes and Retroperitoneum

SYNONYM/ACRONYM: Lymph node sonography.

COMMON USE: To visualize and assess for lymph node enlargement related to disorders such as infection, abscess, tumor, and cancer. Also used as a tool to biopsy and evaluate the progress of therapeutic interventions.

AREA OF APPLICATION: Abdomen, pelvis, and retroperitoneum.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration.

The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Lymph node US is used to evaluate the structure, size, and position of the lymph nodes to examine the retroperitoneum and surrounding tissues. This procedure is used for the evaluation of retroperitoneal pathology, usually lymph node enlargement. US is the preferred diagnostic method because this area is inaccessible to conventional radiography in diagnosing lymphadenopathy, although it can be used in combination with lymphangiography, magnetic resonance imaging (MRI), and computed tomography (CT) to confirm the

diagnosis. The procedure may be used for monitoring the effect of radiation or chemotherapy on the lymph nodes.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect lymphoma
- Determine the location of enlarged nodes to plan radiation and other therapy
- Determine the size or enlargement of aortic and iliac lymph nodes
- Evaluate the effects of medical, radiation, or surgical therapy on the size of nodes or tumors, as evidenced by shrinkage or continued presence of the mass or nodes

POTENTIAL DIAGNOSIS

Normal findings in

- Normal retroperitoneal and intrapelvic node size of 1.5 cm in diameter

Abnormal findings in

- Infection or abscess
- Lymphoma
- Retroperitoneal tumor

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure
- Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging

Other considerations

- Failure to follow dietary/fluid instructions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the lymph nodes and surrounding tissue.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- ▶ Endoscopic retrograde cholangiopancreatography, colonoscopy, and CT of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health-care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Inform the patient that transabdominal US requires a full bladder. Protocols may vary among facilities.
- ▶ Instruct the patient to drink three to four glasses of fluid 90 min before the procedure, and not to void before the procedure.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that food and fluids have been restricted for at least 8 hr prior to the procedure.
- ▶ Ensure that the patient receiving transabdominal US drank three to four glasses of fluid and has not voided.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table; other positions may be used during the examination.

- ▶ Expose the abdominal area and drape the patient.
- ▶ Conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Allow the patient to void, as needed.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography abdomen, biopsy bone marrow, biopsy lymph nodes, CBC, CBC hemoglobin, CBC RBC count, CBC RBC morphology and inclusions, CT abdomen, CT colonoscopy, ESR, gallium scan, KUB study, laparoscopy abdominal, lymphangiogram, and MRI abdomen.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Ultrasound, Pancreas

SYNONYM/ACRONYM: Pancreatic ultrasonography.

COMMON USE: To visualize and assess the pancreas toward diagnosing disorders such as tumor, cancer, obstruction, and cysts. Also used as a tool for biopsy and to evaluate the effectiveness of therapeutic interventions.

AREA OF APPLICATION: Pancreas and upper abdomen.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Pancreatic US is used to determine the size, shape, and position of the pancreas; determine the presence of masses or other abnormalities of the pancreas; and examine the surrounding viscera. Pancreatic US is usually done in combination with computed tomography (CT) or magnetic resonance imaging (MRI) of the pancreas.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect anatomic abnormalities as a consequence of pancreatitis
- Detect pancreatic cancer, as evidenced by a poorly defined mass or a mass in the head of the pancreas that obstructs the pancreatic duct
- Detect pancreatitis, as evidenced by pancreatic enlargement with increased echoes
- Detect pseudocysts, as evidenced by a well-defined mass with absence of echoes from the interior
- Monitor therapeutic response to tumor treatment
- Provide guidance for percutaneous aspiration and fine-needle biopsy of the pancreas

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, contour, and texture of the pancreas

Abnormal findings in

- Acute pancreatitis
- Calculi
- Pancreatic duct obstruction
- Pancreatic tumor
- Pseudocysts

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Attenuation of the sound waves by the ribs, which can impair clear imaging of the right lobe of the pancreas
- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure

Other considerations

- Failure to follow dietary and fluid restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- ▶ Endoscopic retrograde cholangiopancreatography, colonoscopy, and CT of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department, usually by a health-care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing pancreatic function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

RELATED MONOGRAPHS:

- ▶ Related tests include amylase, cancer antigens, CT abdomen, CT pancreas, C peptide, ERCP, KUB study, laparoscopy abdominal, lipase, MRI abdomen, MRI pancreas, peritoneal fluid analysis, and US abdomen.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

Ultrasound, Pelvis (Gynecologic, Nonobstetric)

SYNONYM/ACRONYM: Lower abdominal ultrasound, pelvic gynecologic (GYN) sonogram, pelvic sonography.

COMMON USE: To visualize and assess the pelvis for disorders such as uterine mass, tumor, cancer, cyst, and fibroids. This procedure can also be useful in evaluating ovulation and fallopian tube function related to fertility issues.

U AREA OF APPLICATION: Pelvis and appendix region.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Gynecologic US is used to determine the presence, size, and structure of masses and cysts and determine the position of an intrauterine contraceptive device (IUD); evaluate postmenopausal bleeding; and examine other abnormalities of the uterus, ovaries, fallopian tubes, and vagina. This procedure is done by a transabdominal or transvaginal approach. The transabdominal approach provides a view of the pelvic organs posterior to the bladder. It requires a full bladder, thereby allowing a window for transmission of the US waves, pushing the uterus away from the pubic symphysis, pushing the bowel out of the pelvis, and acting as a reference for comparison in the evaluation of the internal structures of a mass or cyst being examined. The transvaginal approach focuses on the female

reproductive organs and is often used to monitor ovulation over a period of days in patients undergoing fertility assessment. This approach is also used in obese patients or in patients with retroversion of the uterus because the sound waves are better able to reach the organ from the vaginal site. Transvaginal images are significantly more accurate compared to anterior transabdominal images in identifying paracervical, endometrial, and ovarian pathology, and the transvaginal approach does not require a full bladder.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect and monitor the treatment of pelvic inflammatory disease (PID) when done in combination with other laboratory tests
- Detect bleeding into the pelvis resulting from trauma to the area or ascites associated with tumor metastasis
- Detect masses in the pelvis and differentiate them from cysts or solid tumors, as evidenced by differences in sound-wave patterns
- Detect pelvic abscess or peritonitis caused by a ruptured appendix or diverticulitis
- Detect the presence of ovarian cysts and malignancy and determine the type, if possible, as evidenced by size, outline, and change in position of other pelvic organs
- Evaluate the effectiveness of tumor therapy, as evidenced by a reduction in mass size
- Evaluate suspected fibroid tumor or bladder tumor
- Evaluate the thickness of the uterine wall

- Monitor placement and location of an IUD
- Monitor follicular size associated with fertility studies or to remove follicles for in vitro transplantation

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, location, and structure of pelvic organs (e.g., uterus, ovaries, fallopian tubes, vagina); IUD properly positioned within the uterine cavity

Abnormal findings in

- Abscess
- Adnexal torsion
- Appendicitis
- Endometrioma
- Fibroids (leiomyoma)
- Infection
- Nonovarian cyst
- Ovarian cysts
- Ovarian tumor
- Peritonitis
- PID
- Uterine tumor or adnexal tumor

CRITICAL FINDINGS

- Abscess
- Adnexal torsion
- Appendicitis
- Infection
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's

name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Patients with latex allergy; use of the vaginal probe requires the probe to be covered with a condom-like sac, usually made from latex. Latex-free covers are available.

Factors that may impair clear imaging

- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Retained gas or barium from a previous radiological procedure
- Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures.
- Insufficiently full bladder, which fails to push the bowel from the pelvis and the uterus from the symphysis pubis, thereby prohibiting clear imaging of the pelvic organs in transabdominal imaging.

Other considerations

- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that this procedure can assist in assessing pelvic organ function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- ▶ Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by an HCP who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

- ▶ Instruct the patient that a latex or sterile sheath-covered probe will be inserted into the vagina for the transvaginal approach.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Instruct the patient receiving transabdominal US to drink three to four glasses of fluid 90 min before the examination and not to void, because the procedure requires a full bladder. Patients receiving transvaginal US only do not need to have a full bladder.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient receiving transabdominal US drank three to four glasses of fluid and has not voided.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to change into the gown, robe, and foot coverings provided. Remind her not to void before the procedure. Patients receiving transvaginal US do not need to have a full bladder.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table. The right- or left-side-up positions may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- ▶ Expose the abdominal and pelvic area and drape the patient.
- ▶ **Transabdominal approach:** Observe that conductive gel is applied to the skin, and a transducer is moved over the skin while the bladder is distended to obtain images of the area of interest.

- ▶ **Transvaginal approach:** Observe that a covered and lubricated probe is inserted into the vagina and moved to different levels. Images are obtained and recorded.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Allow the patient to void, as needed.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Society (www.cancer.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include cancer antigens, colposcopy, CT abdomen, hysterosalpingography, KUB study, laparoscopy gynecologic, MRI abdomen, Pap smear, and PET pelvis.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Ultrasound, Prostate (Transrectal)

SYNONYM/ACRONYM: Prostate sonography, TRUS.

COMMON USE: To visualize and assess the prostate gland as an adjunct of prostate-specific antigen (PSA) blood testing and examination to assist in diagnosing disorders such as tumor and cancer. Also used to assist in guiding biopsy of the prostate.

AREA OF APPLICATION: Prostate, seminal vesicles.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities

are delivered by a transducer, a candle-shaped device, which is lubricated, sheathed with a condom, and inserted a few inches into the rectum. The waves are bounced back off internal anatomical structures and fluids, converted to

electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Prostate US is used to evaluate the structure, size, and position of the contents of the prostate (e.g., masses). This procedure can evaluate abnormal pathology in prostate tissue, the seminal vesicles, and surrounding perirectal tissue.

Prostate US aids in the diagnosis of prostatic cancer by evaluating palpable nodules as a complement to a digital rectal examination (DRE) or in response to an elevated PSA level. The DRE is a simple procedure used to examine, by palpation, the lower rectum and prostate gland. It is performed by the health-care provider (HCP) who inserts a lubricated, gloved finger into the rectum while the patient is properly positioned. Prostate US can also be used to stage carcinoma and to assist in radiation seed placement.

Micturition disorders can also be evaluated by this procedure. The examination is helpful in monitoring patient response to therapy for prostatic disease.

This procedure is contraindicated for

 Patients with latex allergy; use of the rectal probe requires the probe to be covered with a condom, usually made from latex. Latex-free covers are available.

INDICATIONS

- Aid in the diagnosis of micturition disorders

- Aid in prostate cancer diagnosis
- Assess prostatic calcifications
- Assist in guided needle biopsy of a suspected tumor
- Assist in radiation seed placement
- Determine prostatic cancer staging
- Detect prostatitis

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, consistency, and contour of the prostate gland

Abnormal findings in

- Benign prostatic hypertrophy or hyperplasia
- Micturition disorders
- Perirectal abscess
- Perirectal tumor
- Prostate abscess
- Prostate cancer
- Prostatitis
- Rectal tumor
- Seminal vesicle tumor

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Attenuation of the sound waves by pelvic bones, which can impair clear imaging of the prostate
- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing before the study
- Retained barium from a previous radiological procedure

Other considerations

- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating the prostate gland.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- ▶ Colonoscopy and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health-care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that a small volume enema will be administered prior to the procedure to help remove gas or feces that could interfere with the rectal probe; after the enema a sterile latex- or sheath-covered probe will be inserted into the rectum.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction. The patient may be asked to restrict anticoagulants, aspirin and other salicylates by medical direction for the appropriate number of days prior to the procedure, especially if it is anticipated that a biopsy will be performed.

INTRATEST:**Potential Complications:** N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient on the examination table on his left side with his knees bent toward the chest; other positions may be used during the examination.
- ▶ Expose the rectal area and drape the patient.
- ▶ Cover the rectal probe with a lubricated condom and insert it into the rectum. Inform the patient that he may feel slight pressure as the transducer is inserted. Water may be introduced through the sheath surrounding the transducer.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the study is completed, remove the gel from the skin.

- ▶ **Nutritional Considerations:** There is growing evidence that inflammation and oxidation play key roles in the development of numerous diseases, including prostate cancer. Research also indicates that diets containing dried beans, fresh fruits and vegetables, nuts, spices, whole grains, and smaller amounts of red meats can increase the amount of protective antioxidants. Regular exercise, especially in combination with a healthy diet, can bring about changes in the body's metabolism that decrease inflammation and oxidation.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Administer antibiotics as ordered, after biopsy. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Cancer Institute (www.cancer.gov) or the Prostate Cancer Foundation (www.prostatecancerfoundation.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Decisions regarding the need for and frequency of routine PSA testing or other cancer screening procedures should be made after consultation between the patient and HCP.

Recommendations made by various medical associations and national health organizations regarding prostate cancer screening are moving away from routine PSA screening and toward informed decision making. The American Cancer Society's (ACS) guidelines recommend that discussions about screening should begin at age 50 yr for men at average risk, 45 yr for men at high risk, and 40 yr for men at the highest risk of developing prostate cancer. The most current guidelines for prostate cancer screening of the general population as well as of individuals with increased risk are available from the ACS (www.cancer.org) and the American Urological Association (www.auru.org).

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy prostate, CT pelvis, cystoscopy, cystourethrography voiding, IVP, KUB study, MRI pelvis, proctosigmoidoscopy, PSA, renogram, retrograde ureteropyelography, and semen analysis.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Ultrasound, Scrotal

SYNONYM/ACRONYM: Scrotal sonography, ultrasound of the testes, testicular ultrasound.

COMMON USE: To visualize and assess scrotum structure and function toward diagnosing disorders such as tumor, cancer, undescended testes, and chronic inflammation.

AREA OF APPLICATION: Scrotum.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Scrotal US is used to evaluate the structure, size, and position of the contents of the scrotum and for the evaluation of disorders of the scrotum. It is valuable in determining the internal components of masses (solid versus cystic) and for the evaluation of the testicle, extratesticular and intrascrotal tissues, benign and malignant tumors, and other scrotal pathology. Scrotal US can be performed before or after a radionuclide scan for further clarification of a testicular mass. Extratesticular lesions such as hydrocele, hematocele (blood in the scrotum), and pyocele (pus in the scrotum) can be identified, as can cryptorchidism (undescended testicles).

This procedure is contraindicated for: N/A

INDICATIONS

- Aid in the diagnosis of a chronic inflammatory condition such as epididymitis
- Aid in the diagnosis of a mass and differentiate between a cyst and a solid tumor, as evidenced by specific waveform patterns or the absence of sound waves respectively
- Aid in the diagnosis of scrotal or testicular size, abnormality, or pathology
- Aid in the diagnosis of testicular torsion and associated testicular infarction
- Assist guided needle biopsy of a suspected testicle tumor
- Determine the cause of chronic scrotal swelling or pain
- Determine the presence of a hydrocele, pyocele, spermatocele, or hernia before surgery
- Evaluate the effectiveness of treatment for testicular infections
- Locate an undescended testicle

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of the scrotum and structure of the testes

Abnormal findings in

- Abscess
- Epididymal cyst
- Epididymitis
- Hematoma
- Hydrocele
- Infarction
- Microlithiasis
- Orchitis
- Pyocele
- Scrotal hernia
- Spermatocele
- Testicular torsion
- Tumor, benign or malignant
- Tunica albuginea cyst
- Undescended testicle (cryptorchidism)
- Varicocele

CRITICAL FINDINGS 

- Testicular torsion

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS*Factors that may impair clear imaging*

- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the scrotum.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., surgery or biopsy).
- ▶ Colonoscopy and computed tomography (CT) of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department, by an HCP who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table; other positions may be used during the examination.
- ▶ Expose the abdomen/pelvic area and drape the patient.
- ▶ Lift the penis upward and gently tape it to the lower part of the abdomen. Elevate the scrotum with a rolled towel or sponge for immobilization.
- ▶ Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include AFP, CT pelvis, KUB study, MRI pelvis, and semen analysis.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Ultrasound, Spleen

SYNONYM/ACRONYM: Spleen ultrasonography.

COMMON USE: To visualize and assess the spleen for abscess, trauma, rupture, cancer, and tumor. Also used to evaluate the effectiveness of therapeutic interventions and assist with guided biopsy.

AREA OF APPLICATION: Spleen/left upper quadrant.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Spleen US is used to evaluate the structure, size, and position of the spleen. This test is valuable for determining the internal components of splenic masses (solid versus cystic) and evaluating other splenic pathology, splenic trauma, and left upper quadrant perisplenic tissues. It can be performed to supplement a radionuclide scan or computed tomography (CT). It is especially valuable in patients who are in renal failure, are hypersensitive to contrast medium, or are pregnant, because it does not rely on adequate renal function or the injection of contrast medium to obtain a diagnosis.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect the presence of a subphrenic abscess after splenectomy

- Detect splenic masses; differentiate between cysts or solid tumors (in combination with CT), as evidenced by specific waveform patterns or absence of sound waves respectively; and determine whether they are intrasplenic or extrasplenic
- Determine late-stage sickle cell disease, as evidenced by decreased spleen size and presence of echoes
- Determine the presence of splenomegaly and assess the size and volume of the spleen in these cases, as evidenced by increased echoes and visibility of the spleen
- Differentiate spleen trauma from blood or fluid accumulation between the splenic capsule and parenchyma
- Evaluate the effect of medical or surgical therapy on the progression or resolution of splenic disease
- Evaluate the extent of abdominal trauma and spleen involvement, including enlargement or rupture, after a recent trauma
- Evaluate the spleen before splenectomy performed for thrombocytopenic purpura

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and contour of the spleen and associated structures

Abnormal findings in

- Abscess
- Accessory or ectopic spleen
- Infection
- Lymphatic disease; lymph node enlargement
- Splenic calcifications
- Splenic masses, tumors, cysts, or infarction
- Splenic trauma
- Splenomegaly

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Attenuation of the sound waves by ribs and an aerated left lung, which can impair clear imaging of the spleen
- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status
- Masses near the testing site, which can displace the spleen and cause inaccurate results if confused with splenomegaly
- Dehydration, which can cause failure to demonstrate the boundaries between organs and tissue structures
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study
- Retained barium from a previous radiological procedure

Other considerations

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the function of the spleen.

- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- ▶ Endoscopic retrograde cholangiopancreatography, colonoscopy, and CT of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department by a health-care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects in the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that food and fluids have been restricted for at least 8 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects in the area prior to the procedure.

- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table. The right- or left-side-up position may be used to allow gravity to reposition the liver, gas, and fluid to facilitate better organ visualization.
- ▶ Expose the abdominal area and drape the patient.
- ▶ Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography abdomen, biopsy bone marrow, CBC platelet count, CBC WBC and differential, CT abdomen, KUB study, liver and spleen scan, MRI abdomen, sickle cell screen, US abdomen, and WBC scan.
- ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

Ultrasound, Thyroid and Parathyroid

SYNONYM/ACRONYM: Parathyroid sonography, thyroid echo, thyroid sonography.

COMMON USE: To visualize and assess the thyroid and parathyroid glands for tumor, cancer, and cyst. Also used to stage cancer, guide biopsies, and monitor the effectiveness of therapeutic interventions.

AREA OF APPLICATION: Anterior neck region, parathyroid, thyroid.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, non-invasive, and relatively inexpensive. They take a short time to complete, do

not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a

flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids, converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Thyroid and parathyroid US is used to determine the position, size, shape, weight, and presence of masses of the thyroid gland; enlargement of the parathyroid glands; and other abnormalities of the thyroid and parathyroid glands and surrounding tissues. The primary purpose of this procedure is to determine whether a nodule is a fluid-filled cyst (usually benign) or a solid tumor (possibly malignant). This procedure is useful in evaluating the glands' response to medical treatment or assessing the remaining tissue after surgical resection. US is clearly the procedure of choice when examining the glands of pregnant patients. This procedure is usually done in combination with nuclear medicine imaging procedures and computed tomography (CT) of the neck. Despite the advantages of the procedure, in some cases it may not detect small nodules and lesions (less than 1 cm), leading to false-negative findings.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in determining the presence of a tumor, as evidenced by an irregular border and shadowing at the distal

edge, peripheral echoes, or high- and low-amplitude echoes, depending on the density of the tumor mass; and diagnosing tumor type (e.g., benign, adenoma, carcinoma)

- Assist in diagnosing the presence of a cyst, as evidenced by a smoothly outlined, echo-free amplitude except at the far borders of the mass
- Assist in diagnosis in the presence of a parathyroid enlargement indicating a tumor or hyperplasia, as evidenced by an echo pattern of lower amplitude than that for a thyroid tumor
- Determine the need for surgical biopsy of a tumor or fine-needle biopsy of a cyst
- Differentiate among a nodule, solid tumor, or fluid-filled cyst
- Evaluate the effect of a therapeutic regimen for a thyroid mass or Graves' disease by determining the size and weight of the gland
- Evaluate thyroid abnormalities during pregnancy (mother or baby)

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, contour, and structure of the thyroid and parathyroid glands with uniform echo patterns throughout the glands; no evidence of tumor cysts or nodules in the glands

Abnormal findings in

- Glandular enlargement
- Goiter
- Graves' disease
- Parathyroid tumor or hyperplasia
- Thyroid cysts
- Thyroid tumors (benign or malignant)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Attenuation of the sound waves by the ribs, which can impair clear imaging of the right lobe of the parathyroid

- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations

- Nodules less than 1 cm in diameter may not be detected.
- Nonthyroid cysts may appear the same as thyroid cysts.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing thyroid and parathyroid gland function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium and this test.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US

department by a health-care provider (HCP), with support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table; other positions may be used during the examination.
- ▶ Expose the neck and chest area and drape the patient.
- ▶ Hyperextend the neck, and place a pillow under the patient's shoulders to maintain a comfortable position. (An alternative method of imaging includes the use of a bag filled with water or gel placed over the neck area.)
- ▶ Conductive gel is applied to the skin, and a transducer is moved over the skin to obtain images of the area of interest.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better organ visualization, ask the patient to inhale deeply and hold his or her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting HCP, who will discuss the results with the patient.

- ▶ When the study is completed, remove the gel from the skin.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and

determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antibodies anti-thyroglobulin, biopsy thyroid, chest x-ray, CT thorax, MRI chest, newborn screening, PTH, parathyroid scan, radioactive iodine uptake, thyroid-binding inhibitory immunoglobulin, thyroglobulin, thyroid scan, TSH, thyroxine free, thyroxine total, triiodothyronine free, and triiodothyronine total.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Ultrasound, Venous Doppler, Extremity Studies

SYNONYM/ACRONYM: Venous duplex, venous sonogram, venous ultrasound.

COMMON USE: To assess venous blood flow in the upper and lower extremities toward diagnosing disorders such as deep vein thrombosis, venous insufficiency, causation of pulmonary embolism, varicose veins, and monitor the effects of therapeutic interventions.

AREA OF APPLICATION: Veins of the upper and lower extremities.

CONTRAST: Done without contrast.

DESCRIPTION: Ultrasound (US) procedures are diagnostic, noninvasive, and relatively inexpensive. They take a short time to complete, do not use radiation, and cause no harm to the patient. High-frequency sound waves of various intensities are delivered by a transducer, a flashlight-shaped device, pressed against the skin. The waves are bounced back off internal anatomical structures and fluids,

converted to electrical energy, amplified by the transducer, and displayed as images on a monitor. US is often used as a diagnostic and therapeutic tool for guiding minimally invasive procedures such as needle biopsies and fluid aspiration. The contraindications and complications for biopsy and fluid aspiration are discussed in detail in the individual monographs.

Ultrasound (US) procedures are used to obtain information about the patency of the venous vasculature in the upper and lower extremities to identify narrowing or occlusions of the veins or arteries. In venous Doppler studies, the Doppler identifies moving red blood cells (RBCs) within the vein. The US beam is directed at the vein and through the Doppler transducer while the RBCs reflect the beam back to the transducer. The reflected sound waves or echoes are transformed by a computer into scans, graphs, or audible sounds. Blood flow direction, velocity, and the presence of flow disturbances can be readily assessed. The velocity of the blood flow is transformed as a “swishing” noise, audible through the audio speaker. If the vein is occluded, no swishing sound is heard. For diagnostic studies, the procedure is done bilaterally. The sound emitted by the equipment corresponds to the velocity of the blood flow through the vessel occurring with spontaneous respirations. Changes in these sounds during respirations indicate the possibility of abnormal venous flow secondary to occlusive disease; the absence of sound indicates complete obstruction.

Compression with a transducer augments a vessel for evaluation of thrombosis. Noncompressibility of the vessel indicates a thrombosis. Plethysmography may be performed to determine the filling time of calf veins to diagnose thrombotic disorder of a major vein and to identify incompetent valves in the venous system. An additional method used to evaluate incompetent valves is the Valsalva technique combined with venous duplex imaging.

The ankle-brachial index (ABI) can also be assessed during this study. This noninvasive, simple comparison of blood pressure measurements in the arms and legs can be used to detect peripheral artery disease (PAD). A Doppler stethoscope is used to obtain the systolic pressure in either the dorsalis pedis or the posterior tibial artery. This ankle pressure is then divided by the highest brachial systolic pressure acquired after taking the blood pressure in both of the patient's arms. This index should be greater than 1. When the index falls below 0.5, blood flow impairment is considered significant. Patients should be scheduled for a vascular consult for an abnormal ABI. Patients with diabetes or kidney disease, and some elderly patients, may have a falsely elevated ABI due to calcifications of the vessels in the ankle causing an increased systolic pressure. The ABI test approaches 95% accuracy in detecting PAD. However, a normal ABI value does not absolutely rule out the possibility of PAD for some individuals, and additional tests should be done to evaluate symptoms.

This procedure is contraindicated for: N/A

INDICATIONS

- Aid in the diagnosis of venous occlusion secondary to thrombosis or thrombophlebitis
- Aid in the diagnosis of superficial thrombosis or deep vein thrombosis (DVT) leading to venous occlusion or obstruction, as evidenced by absence of venous flow, especially upon augmentation of the extremity; variations in flow during respirations; or failure of the veins to compress completely when the extremity is compressed

- Detect chronic venous insufficiency, as evidenced by reverse blood flow indicating incompetent valves
- Determine if further diagnostic procedures are needed to make or confirm a diagnosis
- Determine the source of emboli when pulmonary embolism is suspected or diagnosed
- Determine venous damage after trauma to the site
- Differentiate between primary and secondary varicose veins
- Evaluate the patency of the venous system in patients with a swollen, painful leg
- Evaluate PVD
- Monitor the effectiveness of therapeutic interventions

POTENTIAL DIAGNOSIS

Normal findings in

- Normal Doppler venous signal that occurs spontaneously with the patient's respiration
- Normal blood flow through the veins of the extremities with no evidence of vessel occlusion

Abnormal findings in

- Chronic venous insufficiency
- Primary varicose veins
- PVD
- Recannulization in the area of an old thrombus
- Secondary varicose veins
- Superficial thrombosis or DVT
- Venous narrowing or occlusion secondary to thrombosis or thrombophlebitis
- Venous trauma

CRITICAL FINDINGS

- DVT

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Patients with an open or draining lesion.

Factors that may impair clear imaging

- Attenuation of the sound waves by bony structures, which can impair clear imaging of the right lobe of the vessels
- Incorrect placement of the transducer over the desired test site; quality of the US study is very dependent upon the skill of the ultrasonographer
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations

- Cigarette smoking, because nicotine can cause constriction of the peripheral vessels

- Cold extremities, resulting in vasoconstriction that can cause inaccurate measurements
- Occlusion proximal to the site being studied, which would affect blood flow to the area
- An abnormally large or swollen leg, making sonic penetration difficult

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the veins.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Report the presence of a lesion that is open or draining; maintain clean, dry dressing for the ulcer; protect the limb from trauma.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). There should be 24 hr between administration of barium- or iodine-based contrast medium and this test.
- ▶ Endoscopic retrograde cholangiopancreatography, colonoscopy, and computed tomography of the abdomen, if ordered, should be scheduled after this procedure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a US department

by an HCP who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table; other positions may be used during the examination.
- ▶ Expose the area of interest and drape the patient.
- ▶ Conductive gel is applied to the skin, and a transducer is moved over the area to obtain images of the area of interest. Waveforms are visualized and recorded with variations in respirations. Images with and without compression are performed proximally or distally to an obstruction to obtain information about a venous occlusion or obstruction. The procedure can be performed for both arms and legs to obtain bilateral blood flow determination.
- ▶ Do not place the transducer on an ulcer site when there is evidence of venous stasis or ulcer.
- ▶ Ask the patient to breathe normally during the examination. If necessary for bet-

ter organ visualization, ask the patient to inhale deeply and hold his or her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Instruct the patient to continue diet, fluids, and medications, as directed by the HCP.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing coronary artery disease (CAD) or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation of moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in

consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

- ▶ **Social and Cultural Considerations:** Note that numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org), the NHLBI (www.nhlbi.nih.gov), or the Legs for Life (www.legsforlife.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include alveolar/arterial ratio, angiography pulmonary, blood gases, CBC platelet count, CT angiography, D-dimer, FDP, fibrinogen, lung perfusion scan, lung ventilation scan, MRI abdomen, MRI angiography, MRI venography, aPTT, plethysmography, PT/INR, US arterial Doppler lower and upper extremity studies, and venography lower extremities.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Upper Gastrointestinal and Small Bowel Series

SYNONYM/ACRONYM: Gastric radiography, stomach series, small bowel study, upper GI series, UGI.

COMMON USE: To assess the esophagus, stomach, and small bowel for disorders related to obstruction, perforation, weight loss, swallowing, pain, cancer, reflux disease, ulcers, and structural anomalies.

AREA OF APPLICATION: Esophagus, stomach, and small intestine.

CONTRAST: Barium sulfate.

DESCRIPTION: The upper gastrointestinal (GI) series is a radiological examination of the esophagus, stomach, and small intestine after ingestion of barium sulfate, which is a milkshake-like, radiopaque substance. A combination of x-ray and fluoroscopy techniques are used to record the study. Air or gas may be instilled to provide double contrast and better visualization of the lumen of the esophagus, stomach, and duodenum. If perforation or obstruction is suspected, a water-soluble iodinated contrast medium is used. This test is especially useful in the evaluation of patients experiencing dysphagia, regurgitation, gastroesophageal reflux (GER), epigastric pain, hematemesis, melena, and unexplained weight loss. This test is also used to evaluate the results of gastric surgery, especially when an anastomotic leak is suspected. When a small bowel series is included, the test detects disorders of the jejunum and ileum. The patient's position is changed during the examination to allow visualization of the various structures and their function. Images of

the swallowed contrast medium as it moves through the digestive system are visualized on a fluoroscopic screen, recorded, and stored electronically for review. Drugs such as glucagon may be given during an upper GI series to relax the GI tract; drugs such as metoclopramide (Reglan) may be given to accelerate the passage of the barium through the stomach and small intestine.

When the small bowel series is performed separately, the patient may be asked to drink several glasses of barium, or enteroclysis may be used to instill the barium. With enteroclysis, a catheter is passed through the nose or mouth and advanced past the pylorus and into the duodenum. Barium, followed by methylcellulose solution, is instilled via the catheter directly into the small bowel.

Pediatrics An upper GI series is usually done in the pediatric population to diagnose the cause of recurrent GI signs (bleeding) and symptoms. The etiology is often related to age. In infants, recurrent symptoms such as vomiting after feeding, poor feeding,

poor weight gain, and abdominal pain (evidenced by frequent crying during or after a feeding) may trigger an investigation. The most common causes of upper or lower GI bleeding in infants up to 1 mo include allergies to milk proteins, anorectal fissures, bacterial enteritis, coagulopathy, esophagitis, Hirschsprung's disease, intussusception, peptic ulcer, stenosis, varices, or Meckel's diverticulum. Children between 2 to 23 mo are most commonly diagnosed with allergies to milk proteins, anorectal fissures, esophagitis caused by gastroesophageal reflux (GER), gastritis, intussusception, Meckel's diverticulum, NSAID-induced ulcer, and ingested foreign body. Pediatric patients 24 mo and older are most commonly diagnosed with esophageal varices, Mallory Weiss tears, peptic ulcer, related to *Helicobacter pylori* infection or peptic ulcer secondary to some other type of systemic disease (e.g., Crohn's disease or IBD). Other abnormal findings in this age group include IBD, polyps, malignancy, sepsis, and Meckel's diverticulum.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients suspected of having upper GI perforation, unless water-soluble iodinated contrast medium, such as Gastrografin, is used.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of non-ionic contrast or an alternative non-contrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) ***because iodinated contrast is nephrotoxic.***
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, ***because of their risk of contrast-induced renal failure.***
- ◆ Patients with an intestinal obstruction ***because the barium or water from the enema may make the condition worse.***

INDICATIONS

- Determine the cause of regurgitation or epigastric pain
- Determine the presence of neoplasms, ulcers, diverticula, obstruction, foreign body, and hiatal hernia
- Evaluate suspected GER, inflammatory process, congenital anomaly, motility disorder, or structural change

- Evaluate unexplained weight loss or anemia
- Identify and locate the origin of hematemesis

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, shape, position, and functioning of the esophagus, stomach, and small bowel

Abnormal findings in

- Achalasia
- Cancer of the esophagus
- Chalasis
- Congenital abnormalities
- Duodenal cancer, and ulcers
- Esophageal diverticula, motility disorders, ulcers, varices, and inflammation
- Foreign body
- Gastric cancer or tumors, and ulcers
- Gastritis
- Hiatal hernia
- Perforation of the esophagus, stomach, or small bowel
- Polyps
- Small bowel tumors
- Strictures

CRITICAL FINDINGS

- Foreign body
- Perforated bowel
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's

name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
 - Patients with swallowing problems may aspirate the barium, which could interfere with the procedure and cause patient complications.
 - Possible constipation or partial bowel obstruction caused by retained barium in the small bowel or colon may affect test results.
 - This procedure should be done after a kidney x-ray (IV pyelography) or computed tomography of the abdomen or pelvis.
 - Consultation with the appropriate HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Pediatric & Geriatric Imaging**
Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the esophagus, stomach, and small intestine.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that this procedure is performed before a barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus).
- ▶ If iodinated contrast medium (e.g., Gastrografin) is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and

continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**

- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the procedure. Inform the patient that the procedure is usually performed in a radiology department by an HCP, with support staff, and takes approximately 30 to 60 min. **Pediatric Considerations** Preparing children for an upper GI examination depends on the age of the child. Encourage parents to be truthful about unpleasant sensations the child may experience during the procedure and to use words that they know their child will understand. Toddlers and preschool-age children have a very short attention span, so the best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with the child during the procedure.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain to the patient that he or she will be asked to drink a milkshake-like solution that has an unpleasant chalky taste.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities.
- ▶ **Pediatric Considerations** The fasting period prior to the time of the examination depends on the child's age. General guidelines are that the patient should not eat for the period of time between normal meals: newborn 2 to 3 hr; infants to 4 yr: 3 to 4 hr; 5 yr through adolescence: 6 to 8 hr.

INTRATEST:**Potential Complications:**

Complications include allergic reaction to the contrast medium, aspiration of the barium, significant diarrhea **related to use of Gastrografin**, and partial bowel obstruction caused by thickened or congealed barium.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary and fluid restrictions for 8 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.

Upper Gastrointestinal Series

- ▶ Place the patient on the x-ray table in a supine position, or ask the patient to stand in front of a fluoroscopy screen.
- ▶ Instruct the patient to take several swallows of the barium mixture through a straw while images are taken of the pharyngeal motion. An effervescent agent may also be administered to introduce air into the stomach.

Pediatric Considerations For infants, barium contrast may be mixed with a small amount of the infant's feeding to take in a bottle. If the patient is unable to drink the barium, a thin, flexible tube may be placed through his or her nose to get the barium into the esophagus.

Small Bowel Series

- ▶ If the small bowel is to be examined after the upper GI series, instruct the patient to drink an additional glass of barium while the small intestine is observed for passage of barium. Images are taken at 30- to 60-min intervals until

the barium reaches the ileocecal valve. This process can last up to 5 hr, with follow-up images taken at 24 hr.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- ▶ Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if iodine is used.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient to take a mild laxative and increase fluid intake (four glasses) to aid in the elimination of barium unless contraindicated. **Pediatric Considerations** Instruct the parents of pediatric patients to hydrate the child with electrolyte fluid post barium enema.
- ▶ **Geriatric Considerations** Chronic dehydration can also result in frequent bouts of constipation. Therefore, after the procedure, elderly patients should be encouraged to hydrate with fluids containing electrolytes (e.g., Gatorade, Gatorade low calorie, for diabetics, or Pedialyte) and to use a mild laxative daily until the stool is back to normal color.
- ▶ Inform the patient that his or her stool will be white or light in color for 2 to 3 days. If the patient is unable to eliminate the barium, or if the stool does not return to normal color, the patient should notify the HCP.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include barium enema, barium swallow, capsule endoscopy, CT abdomen, endoscopic retrograde cholangiopancreatography, esophageal manometry, fecal analysis, gastric acid stimulation test, gastric emptying scan, gastrin stimulation test, gastroesophageal reflux scan, *H. pylori* antibody, KUB study, Meckel's diverticulum scan, MRI abdomen, and US pelvis.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Urea Breath Test

SYNONYM/ACRONYM: PY test, C-14 urea breath test, breath test, pylori breath test, UBT.

COMMON USE: To assist in diagnosing a gastrointestinal infection and ulceration of the stomach or duodenum related to a *Helicobacter pylori* infection.

AREA OF APPLICATION: Stomach.

CONTRAST: Radioactive C-14 urea in capsule form.

DESCRIPTION: The C-14 urea breath test (UBT) is used to assist in the diagnosis of *Helicobacter pylori* infection. *H. pylori* is a bacteria that can infect the stomach lining. It has been implicated as the cause of many gastrointestinal conditions, including the development of duodenal and gastric ulcers. The UBT is a simple, noninvasive diagnostic nuclear medicine procedure that requires the patient to swallow a small amount of radiopharmaceutical C-14-labeled urea in a capsule with lukewarm water. In the presence of urease, an enzyme secreted by *H. pylori* in the gut, the urea in the capsule is broken down into nitrogen and C-14-labeled carbon dioxide (CO₂). The labeled CO₂ is

absorbed through the stomach lining into the blood and excreted by the lungs. Breath samples are collected and trapped in a Mylar balloon. The C-14 urea is counted and quantitated with a liquid scintillation counter. The UBT can also be used to indicate the elimination of *H. pylori* infection after treatment with antibiotics. Other tests used to detect the presence of *H. pylori* include a blood *H. pylori* antibody test, a stool antigen test, and stomach biopsy.

This procedure is contraindicated for

- ▶  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a

procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

-  Patients who have taken antibiotics, Pepto-Bismol, or bismuth in the past 30 days.
-  Patients who have taken sucralfate in the past 14 days.
-  Patients who have used a proton pump inhibitor within the past 14 days.

INDICATIONS

- Aid in detection of *H. pylori* infection in the stomach
- Monitor eradication of *H. pylori* infection following treatment regimen
- Evaluate new-onset dyspepsia

POTENTIAL DIAGNOSIS

Normal findings in

- Negative for *H. pylori*: Less than 50 dpm (disintegrations per minute)

Abnormal findings in

- Indeterminate for *H. pylori*: 50 to 199 dpm
- Positive for *H. pylori*: Greater than 200 dpm

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Patients who have had resective gastric surgery have the potential for resultant bacterial overgrowth (non-*H. pylori* urease), which can cause a false-positive result.
- Achlorhydria can cause a false-positive result.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in diagnosing an infection of the stomach or intestine.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in premenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Address concerns about pain and explain that there should be no discomfort during the procedure. Inform the patient that the procedure is done in the nuclear medicine department by technologists and support staff and usually takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast, restrict fluids, and, by medical direction, withhold medication for 6 hr prior to the procedure. Protocols may vary among facilities.

INTRATEST:**Potential Complications:** N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary and medication restrictions and pretesting preparations; assure that food, fluids, and medications have been restricted for at least 6 hr prior to the procedure.
- ▶ Instruct the patient to blow into a balloon prior to the start of the procedure to collect a sample of breath.
- ▶ Instruct the patient to swallow the C-14 capsule directly from a cup, followed by 20 mL of lukewarm water. Provide an additional 20 mL of lukewarm water for the patient to drink at 3 min after the dose.
- ▶ Take breath samples at different periods of time by instructing the patient to take in a deep breath and hold it for approximately 5 to 10 sec before exhaling through a straw into a Mylar balloon.
- ▶ Note that samples are counted on a liquid scintillation counter (LSC) and recorded in disintegrations per minute.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet and medication, as directed by the HCP.

- ▶ Unless contraindicated, advise patient to drink increased amounts of fluids for 12 to 24 hr to eliminate the radionuclide from the body.
- ▶ If a woman who is breastfeeding must have a breath test, she should not breastfeed the infant until the radionuclide has been eliminated. She should be instructed to express the milk and discard it during a 3-day period to prevent cessation of milk production.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of the procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include EGD, gastric emptying scan, *H. pylori* antibody, KUB study, and UGI.
- ▶ See the Gastrointestinal System table at the end of the book for related tests by body system.

Urea Nitrogen, Blood

SYNONYM/ACRONYM: BUN.

COMMON USE: To assist in assessing for renal function toward diagnosing disorders such as kidney failure and dehydration. Also used in monitoring the effectiveness of therapeutic interventions such as hemodialysis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.357)
Newborn–3 yr	5–17 mg/dL	1.8–6.1 mmol/L
4–13 yr	7–17 mg/dL	2.5–6.1 mmol/L
14 yr–adult	8–21 mg/dL	2.9–7.5 mmol/L
Adult older than 90 yr	10–31 mg/dL	3.6–11.1 mmol/L

DESCRIPTION: Unlike fats and carbohydrates, protein cannot be stored by the body. The amino acids and nitrogen used to make proteins are either obtained from dietary sources or from the normal turnover of aging cells in the body. Urea is a nonprotein nitrogen (NPN) compound formed in the liver from ammonia and excreted by the kidneys as an end product of protein metabolism. Other NPN compounds excreted by the kidneys include uric acid and creatinine. Blood urea nitrogen (BUN) levels reflect the balance between the amount of nitrogen ingested and excreted which is a representation of overall protein metabolism. BUN and creatinine values are commonly evaluated together. The normal BUN/creatinine ratio is 15:1 to 24:1. (e.g., if a patient has a BUN of 15 mg/dL, the creatinine should be approximately 0.6 to 1 mg/dL). BUN is used in the following calculation to estimate serum osmolality: $(2 \times \text{Na}^+) + (\text{glucose}/18) + (\text{BUN}/2.8)$.

This procedure is contraindicated for: N/A

INDICATIONS

- Assess nutritional support
- Evaluate hemodialysis therapy
- Evaluate hydration
- Evaluate liver function
- Evaluate patients with lymphoma after chemotherapy (tumor lysis)

- Evaluate renal function
- Monitor the effects of drugs known to be nephrotoxic or hepatotoxic

POTENTIAL DIAGNOSIS

Increased in

- Acute renal failure (*related to decreased renal excretion*)
- Chronic glomerulonephritis (*related to decreased renal excretion*)
- Congestive heart failure (*related to decreased blood flow to the kidneys, decreased renal excretion, and accumulation in circulating blood*)
- Decreased renal perfusion (*reflects decreased renal excretion and increased blood levels*)
- Diabetes (*related to decreased renal excretion*)
- Excessive protein ingestion (*related to increased protein metabolism*)
- Gastrointestinal (GI) bleeding (*excessive blood protein in the GI tract and increased protein metabolism*)
- Hyperalbuminemia (*related to increased protein metabolism*)
- Hypovolemia (*related to decreased blood flow to the kidneys, decreased renal excretion, and accumulation in circulating blood*)
- Ketoacidosis (*dehydration from ketoacidosis correlates with decreased renal excretion of urea nitrogen*)
- Muscle wasting from starvation (*related to increased protein metabolism*)

- Neoplasms (*related to increased protein metabolism or to decreased renal excretion*)
- Nephrotoxic agents (*related to decreased renal excretion and accumulation in circulating blood*)
- Pyelonephritis (*related to decreased renal excretion*)
- Shock (*related to decreased blood flow to the kidneys, decreased renal excretion, and accumulation in circulating blood*)
- Urinary tract obstruction (*related to decreased renal excretion and accumulation in circulating blood*)

Decreased in

- Inadequate dietary protein (*urea nitrogen is a by-product of protein metabolism; less available protein is reflected in decreased BUN levels*)
- Low-protein/high-carbohydrate diet (*urea nitrogen is a by-product of protein metabolism; less available protein is reflected in decreased BUN levels*)
- Malabsorption syndromes (*urea nitrogen is a by-product of protein metabolism; less available protein is reflected in decreased BUN levels*)
- Pregnancy
- Severe liver disease (*BUN is synthesized in the liver, so liver damage results in decreased levels*)

CRITICAL FINDINGS

Adults

- Greater than 100 mg/dL (SI: Greater than 35.7 mmol/L) (nondialysis patients)

Children

- Greater than 55 mg/dL (SI: Greater than 19.6 mmol/L) (nondialysis patients)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms especially fluid imbalance. It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

A patient with a grossly elevated BUN may have signs and symptoms including acidemia, agitation, confusion, fatigue, nausea, vomiting, and coma. Possible interventions include treatment of the cause, administration of IV bicarbonate, a low-protein diet, hemodialysis, and caution with respect to prescribing and continuing nephrotoxic medications.

INTERFERING FACTORS

- Drugs, substances, and vitamins that may increase BUN levels include acetaminophen, alanine, aldatense, alkaline antacids, amphotericin B, antimony

compounds, arsenicals, bacitracin, bismuth subsalicylate, capreomycin, carbenoxolone, carbutamide, cephalosporins, chloral hydrate, chloramphenicol, chlorthalidone, colistimethate, colistin, cotrimoxazole, dexamethasone, dextran, diclofenac, doxycycline, ethylene glycol, gentamicin, guanethidine, guanoxan, ibuprofen, ifosfamide,

ipodate, kanamycin, mephesisin, metolazone, mitomycin, neomycin, phosphorus, plicamycin, tertatolol, tetracycline, triamterene, triethylene-melamine, viomycin, and vitamin D.

- Drugs that may decrease BUN levels include acetohydroxamic acid, chloramphenicol, fluorides, paramethasone, phenothiazine, and streptomycin.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to uremia and decreased immune response; venous catheters; Foley catheters; endotracheal tubes</i>)	Temperature; elevated white cell count; cloudy urine; sediment in urine; blood in urine	Monitor urinary output; assess urine color, odor, presence of blood; monitor and trend temperature and white cell count; obtain urine for culture and sensitivity as required; administer prescribed antibiotics; avoid long-term indwelling catheters; encourage frequent personal and oral hygiene; encourage use of gentle soaps; assist in preventing skin breakdown; use meticulous care and sterile technique in provision of care for peripheral or venous catheters
Renal function (<i>Related to renal ischemia associated with shock, sepsis, hypovolemia; postoperative injury; trauma; nephrotoxic drugs [aminoglycoside, heavy metals, radiographic contrast]; renal</i>	Increased BUN; increased creatinine; decreased creatinine clearance; increased urine specific gravity (greater than 1.029); hematuria; proteinuria; decreased urine output less than 400 mL/day (with adequate intake and no fluid loss); weight gain; elevated	Monitor, record, and trend intake and output; monitor urine specific gravity; monitor and trend renal specific urine and blood studies, BUN, creatinine, sodium, potassium, magnesium, pH, urinalysis, HGB/HCT; monitor and trend weight daily; assess and monitor for edema, JVD, hypertension, adventitious breath sounds, impaired gas exchange; use

(table continues on page 1546)

Problem	Signs & Symptoms	Interventions
vascular occlusion; hemolytic transfusion reaction; decreased cardiac output; tubular necrosis; obstruction; tumor; medications [NSAID, ACE, immuno-suppressants, antineoplastics, antifungals]	potassium; elevated phosphate; decreased calcium; decreased sodium; increased magnesium; metabolic acidosis; decreased HGB/ HCT	pulse oximetry; administer prescribed oxygen; administer prescribed hemodialysis; administer prescribed medications (diuretics); administer prescribed fluids; consider renal function with antibiotic administration
Cardiac output (Related to excess fluid volume; pericarditis; electrolyte imbalance; toxin accumulation; dysrhythmias; altered cardiac muscle contractility secondary to heart failure)	Weak peripheral pulses; slow capillary refill; decreased urinary output; cool, clammy skin; tachypnea; dyspnea; altered level of consciousness; abnormal heart sounds; fatigue; hypoxia; loud holosystolic murmur; EKG changes; increased JVD	Assess peripheral pulses and capillary refill; monitor blood pressure and check for orthostatic changes; assess respiratory rate, breath sounds, and orthopnea; assess skin color and temperature; assess level of consciousness; monitor urinary output; use pulse oximetry to monitor oxygenation; monitor EKG; assess for third heart sound (indicative of HF or pericarditis); administer ordered inotropic and peripheral vasodilator medications, nitrates; provide oxygen administration; administer as prescribed (sodium bicarbonate, glucose, insulin drip, potassium excretion resin, calcium salt)
Fluid volume (Related to excess fluid and sodium intake; compromised renal function)	Excess: edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values; distended neck veins; tachycardia;	Record daily weight and monitor trends; record accurate intake and output; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium,

Problem	Signs & Symptoms	Interventions
	restlessness; presence of S3 heart sound	hemoglobin, hematocrit, sodium); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; assess and trend heart rate and blood pressure; assess for symptoms of fluid overload such as JVD, shortness of breath, dyspnea, crackles; provide low sodium diet; administer prescribed diuretic; administer prescribed antihypertensive; elevate feet when sitting; monitor oxygenation with pulse oximetry; administer oxygen as appropriate; elevate the head of the bed; administer prescribed antihypertensives; administer IV medications with the least amount of fluid; prepare for hemodialysis as appropriate

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing kidney function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen

collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Monitor intake and output for fluid imbalance in renal dysfunction and dehydration.
- ▶ **Nutritional Considerations:** Greater than 100 nitrogen balance is commonly used as a nutritional assessment tool to indicate protein change. In healthy individuals, protein anabolism and catabolism are in equilibrium. During various disease states, nutritional intake decreases, resulting in a negative balance. During recovery from illness and with proper nutritional support, the nitrogen balance becomes positive. BUN is an important analyte to measure during administration of total parenteral nutrition (TPN). Educate the patient, as appropriate, in dietary adjustments required to maintain proper nitrogen balance. Inform the patient that the requesting HCP may prescribe TPN as part of the treatment plan.
- ▶ **Nutritional Considerations:** An elevated BUN can be caused by a high-protein diet or dehydration. Unless medically restricted, a healthy diet consisting of the five food groups of the USDA's MyPlate dietary guide should be consumed daily. Water consumption should include six to eight 8-oz glasses of water per day, or water consumption equivalent to half of the body's weight in fluid ounces (32 fl oz = 1 qt; 34 fl oz = 1 L).
- ▶ Recognize anxiety related to test results.
- ▶ Depending on the results of this procedure, additional testing may be performed

to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient how to accurately measure and record urine output.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that hemodialysis may be necessary if renal function fails to improve
- ▶ States the importance of adhering to the specified fluid limit

Skills

- ▶ Demonstrates proficiency in tracking and documenting intake and output
- ▶ Demonstrates proficiency in taking and documenting temperature

Attitude

- ▶ Complies with the request for frequent personal and oral hygiene to decrease infection risk
- ▶ Complies with the request to take prescribed medication as ordered

RELATED MONOGRAPHS:

- ▶ Related tests include anion gap, antimicrobial drugs, biopsy kidney, calcium, calculus kidney stone panel, CT spleen, creatinine, creatinine clearance, cytology urine, cystoscopy, electrolytes, gallium scan, glucose, glycated hemoglobin, 5-HIAA, IVP, ketones, magnesium, MRI venography, microalbumin, osmolality, oxalate, phosphorus, protein total and fractions, renogram, US abdomen, US kidney, UA, urea nitrogen urine, and uric acid.
- ▶ Refer to the Genitourinary and Hepatobiliary systems tables at the end of the book for related tests by body system.

Urea Nitrogen, Urine

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess renal function related to the progression of disorders such as diabetes, liver disease, and renal disease.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Spectrophotometry)

Conventional Units	SI Units (Conventional Units × 35.7)
12–20 g/24 hr	428–714 mmol/24 hr

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Diabetes (*related to increased protein metabolism*)
- Hyperthyroidism
- Increased dietary protein (*related to increased protein metabolism*)
- Postoperative period

Decreased in

- Liver disease (*BUN is synthesized in the liver, so liver damage results in decreased levels*)
- Low-protein/high-carbohydrate diet (*urea nitrogen is a by-product of*

protein metabolism; less available protein is reflected in decreased BUN levels)

- Normal-growing pediatric patients (*increased demand for protein; less available protein is reflected in decreased BUN levels*)
- Pregnancy (*increased demand for protein; less available protein is reflected in decreased BUN levels*)
- Renal disease (*related to decreased renal excretion*)
- Toxemia (*related to hypertension and decreased renal excretion*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Urethrography, Retrograde

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess urethral patency in order to evaluate the success of surgical interventions on patients who have urethral structures or other anomalies that interfere with urination.

AREA OF APPLICATION: Urethra.

CONTRAST: Radiopaque contrast medium.

DESCRIPTION: Retrograde urethrography is performed almost exclusively in male patients. It uses contrast medium, either injected or instilled via a catheter into the urethra, to visualize the membranous, bulbar, and penile portions, particularly after surgical repair of the urethra to assess the success of the surgery. The posterior portion of the urethra is visualized better when the procedure is performed with voiding cystourethrography. In women, it may be performed after surgical repair of the urethra to assess the success of the surgery and to assess structural abnormalities in conjunction with an evaluation for voiding dysfunction.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium,

the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure.**
- ◆ Patients with bleeding disorders **because the puncture site may not stop bleeding.**

INDICATIONS

- Aid in the diagnosis of urethral strictures, lacerations, diverticula, and congenital anomalies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, shape, and course of the membranous, bulbar, and penile portions of the urethra in male patients
- If the prostatic portion can be visualized, it also should appear normal

Abnormal findings in

- Congenital anomalies, such as urethral valves and perineal hypospadias

- False passages in the urethra
- Prostatic enlargement
- Tumors of the urethra
- Urethral calculi
- Urethral diverticula
- Urethral fistulas
- Urethral strictures indicated by a narrowing and lacerations

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the urethral patency.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the procedure. Inform the patient that the procedure is performed in a cystoscopy room by an HCP, with support staff, and takes approximately 30 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological

support before, during, and after the procedure.

- ▶ Inform the patient that some pressure may be experienced when the catheter is inserted and contrast medium is instilled.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Complications include allergic reaction to the contrast medium and bleeding.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to lie still during the procedure because movement produces unclear images.
- ▶ Obtain and record the patient's baseline vital signs.
- ▶ Place the patient on the table in a supine position.
- ▶ A single plain film is taken of the bladder and urethra.
- ▶ A catheter is filled with contrast medium to eliminate air pockets and is inserted until the balloon reaches the meatus. Inform the patient that the contrast medium may cause a temporary flushing of the face, a feeling of warmth, urticaria, headache, vomiting, or nausea.

- ▶ After three-fourths of the contrast medium is injected, another image is taken while the remainder of the contrast medium is injected.
- ▶ The procedure may be done on female patients using a double balloon to occlude the bladder neck from above and below the external meatus.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual activities, as directed by the HCP.
- ▶ Monitor vital and neurological signs every 15 min until they return to pre-procedure levels.
- ▶ Monitor fluid intake and urinary output for 24 hr after the procedure. Decreased urine output may indicate impending renal failure.
- ▶ Monitor for signs and symptoms of sepsis, including fever, chills, and severe pain in the kidney area.
- ▶ Instruct the patient to drink plenty of fluids to prevent stasis and to prevent the buildup of bacteria.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CT abdomen, CT pelvis, cystometry, cystoscopy, IVP, MRI abdomen, PSA, renogram, retrograde ureteropyelography, urinalysis, and voiding cystourethrography.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Uric Acid, Blood

SYNONYM/ACRONYM: Urate.

COMMON USE: To monitor uric acid levels during treatment for gout and evaluation of tissue destruction, liver damage, renal function, and monitor the effectiveness of therapeutic interventions.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable. Note: Rasburicase will rapidly decrease uric acid in specimens left at room temperature. If patients are receiving this medication, collect the blood sample in a prechilled green-top (heparin) tube and transport in an ice slurry.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.059)
1–30 d		
Male	1.3–4.9 mg/dL	0.08–0.29 mmol/L
Female	1.4–6.2 mg/dL	0.08–0.37 mmol/L
1–3 mo		
Male	1.4–5.3 mg/dL	0.08–0.31 mmol/L
Female	1.4–5.8 mg/dL	0.08–0.34 mmol/L
4–12 mo		
Male	1.5–6.4 mg/dL	0.09–0.38 mmol/L
Female	1.4–6.2 mg/dL	0.08–0.37 mmol/L
1–3 yr		
Male & female	1.8–5 mg/dL	0.11–0.3 mmol/L
4–6 yr		
Male & female	2.2–4.7 mg/dL	0.13–0.28 mmol/L
7–9 yr		
Male & female	2–5 mg/dL	0.12–0.3 mmol/L
10–12 yr		
Male & female	2.3–5.9 mg/dL	0.14–0.35 mmol/L
13–15 yr		
Male	3.1–7 mg/dL	0.18–0.41 mmol/L
Female	2.3–6.4 mg/dL	0.14–0.38 mmol/L
16–18 yr		
Male	2.1–7.6 mg/dL	0.12–0.45 mmol/L
Female	2.4–6.6 mg/dL	0.14–0.39 mmol/L
19 yr–Adult		
Male	4–8 mg/dL	0.24–0.47 mmol/L
Female	2.5–7 mg/dL	0.15–0.41 mmol/L

(table continues on page 1554)

Age	Conventional Units	SI Units (Conventional Units × 0.059)
Adult older than 60 yr		
Male	4.2–8.2 mg/dL	0.25–0.48 mmol/L
Female	3.5–7.3 mg/dL	0.21–0.43 mmol/L

Therapeutic target for patients with gout: Less than 6 mg/dL (SI: Less than 0.4 mmol/L).

DESCRIPTION: Uric acid is the end product of purine metabolism. Purines are important constituents of nucleic acids; purine turnover occurs continuously in the body, producing substantial amounts of uric acid even in the absence of purine intake from dietary sources such as organ meats (e.g., liver, thymus gland and/or pancreas [sweetbreads], kidney), legumes, and yeasts. Uric acid is filtered, absorbed, and secreted by the kidneys and is a common constituent of urine. Serum urate levels are affected by the amount of uric acid produced and by the efficiency of renal excretion. Values can vary based on diet, gender, body size, level of exercise, level of stress, and regularity in consumption of alcohol. Elevated uric acid levels can indicate conditions of critical cellular injury or destruction; hyperuricemia has an association with hypertension, hypertriglyceridemia, obesity, myocardial infarct, renal disease, and diabetes. Rasburicase is a medication used in the treatment and prevention of acute hyperuricemia related to tumor lysis syndrome in children and for leukemias and lymphomas related to the toxic effects of chemotherapy. Rasburicase is a recombinant form of uricase oxidase, an enzyme that converts uric acid to allantoin, a much more soluble and effectively excreted substance than uric acid.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of gout when there is a family history (autosomal dominant genetic disorder) or signs and symptoms of gout, indicated by elevated uric acid levels
- Determine the cause of known or suspected renal calculi
- Evaluate the extent of tissue destruction in infection, starvation, excessive exercise, malignancies, chemotherapy, or radiation therapy
- Evaluate possible liver damage in eclampsia, indicated by elevated uric acid levels
- Monitor the effects of drugs known to alter uric acid levels, either as a side effect or as a therapeutic effect

POTENTIAL DIAGNOSIS

Increased in

Conditions that result in high cellular turnover release nucleic acids into circulation, which are converted to uric acid by the liver.

- Acute tissue destruction as a result of starvation or excessive exercise (*related to cellular destruction*)
- Alcoholism
- Chemotherapy and radiation therapy (*related to high cellular turnover*)
- Chronic lead toxicity (*cellular destruction related to hemolysis*)
- Congestive heart failure (*related to cellular destruction*)
- Diabetes (*decreased renal excretion results in increased blood levels*)

- Down syndrome
- Eclampsia
- Excessive dietary purines (*purines are nucleic acid bases converted to uric acid by the liver*)
- Glucose-6-phosphate dehydrogenase deficiency (*cellular destruction related to hemolysis*)
- Gout (*usually related to excess dietary intake*)
- Hyperparathyroidism
- Hypertension (*related to effects on renal excretion*)
- Hypoparathyroidism (*related to disturbances in calcium and phosphorus homeostasis*)
- Lactic acidosis (*cellular destruction related to shock*)
- Lead poisoning (*cellular destruction related to hemolysis*)
- Lesch-Nyhan syndrome (*related to disorder of uric acid metabolism*)
- Multiple myeloma (*related to high cell turnover*)
- Pernicious anemia (*cellular destruction related to hemolysis*)
- Polycystic kidney disease (*related to decreased renal excretion, which results in increased blood levels*)
- Polycythemia (*related to increased cellular destruction*)
- Psoriasis
- Sickle cell anemia (*cellular destruction related to hemolysis*)
- Tumors (*related to high cell turnover*)
- Type III hyperlipidemia

Decreased in

- Fanconi's syndrome (*related to increased renal excretion*)
- Low-purine diet (*related to insufficient nutrients for liver to synthesize uric acid*)
- Severe liver disease (*uric acid synthesis occurs in the liver*)
- Wilson's disease (*affects normal liver function and is related to impaired tubular absorption*)

CRITICAL FINDINGS

Adults

- Greater than 13 mg/dL (SI: Greater than 0.8 mmol/L)

Children

- Greater than 12 mg/dL (SI: Greater than 0.7 mmol/L)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms especially fluid imbalance.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Symptoms of acute renal dysfunction and/or failure associated with hyperuricemia include altered mental status, nausea and vomiting, fluid overload, pericarditis, and seizures. Prophylactic measures against the development of hyperuricemia should be undertaken before initiation of chemotherapy. Possible interventions include discontinuing medications that increase serum urate levels or produce

acidic urine (e.g., thiazides and salicylates); administration of fluids with sodium bicarbonate as an additive to IV solutions to promote hydration and alkalization of the urine to a pH greater than 7; administration of allopurinol 1 to 2 days before chemotherapy; monitoring of serum electrolyte, uric acid, phosphorus, calcium, and creatinine levels; and monitoring for ureteral obstruction by urate calculi using computed tomography or ultrasound studies. Possible interventions for advanced renal insufficiency and subsequent renal failure may include peritoneal dialysis or hemodialysis.

INTERFERING FACTORS

- Drugs and substances that may increase uric acid levels include acetylsalicylic acid (low doses), aldatense, aminothiadiazole, anabolic steroids, antineoplastic agents, atenolol, azathioprine, azathymine, azauridine, chlorambucil, chlorthalidone, cisplatin, corn oil, cyclosporine, cyclothiazide, cytarabine, diapamide, diuretics, ethacrynic acid, ethambutol, ethoxzamide, flumethiazide, hydrochlorothiazide, hydroflumethiazide, ibufenac, ibuprofen, levarterenol, mefruside, mercaptopurine, methicillin, methotrexate, methoxyflurane, methyclothiazide, mitomycin, morinamide, polythiazide, prednisone, pyrazinamide, quinethazone, salicylate, spironolactone, tacrolimus, theophylline, thiazide diuretics, thioguanine, thiotepa, triamterene, trichlormethiazide, vincristine, and warfarin.
- Drugs that may decrease uric acid levels include allopurinol, aspirin (high doses), azathioprine, benzbromaron, benziodarone, canola oil, chlorothiazide (given IV), chlorpromazine, chlorprothixene, cinchophen, clofibrate, corticosteroids, corticotropin, coumarin, dicumarol, enalapril, fenofibrate, flufenamic acid, guaifenesin, iodipamide, iodopyracet, iopanoic acid, ipodate, lisinopril, mefenamic acid, mersalyl, methotrexate, oxyphenbutazone, phenindione, phenolsulfonphthalein, probenecid, radiographic agents, rasburicase, seclazone, sulfinpyrazone, and verapamil.
- Rasburicase will rapidly decrease uric acid in specimens left at room temperature. Specimens must be collected in prechilled tubes, transported in an ice slurry, and tested within 4 hr of collection.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fluid volume (<i>Related to decreased glomerular filtration or the resence of the diuretic stage of renal disease</i>)	Overload: edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values. Deficit: decreased urinary output, fatigue, sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status	Manage underlying cause of fluid alteration; record accurate intake and output; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate to adjust oral and IV fluids to provide optimal hydration status

Problem	Signs & Symptoms	Interventions
Confusion (<i>Related to an alteration in fluid and electrolytes, hepatic disease, renal disease</i>)	Disorganized thinking, restlessness, irritability, altered concentration and attention span, changeable mental function over the day, hallucinations	Treat the medical condition; correlate confusion with the need to reverse altered electrolytes; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or restraints; consider pharmacological interventions; record accurate intake and output to assess fluid status
Electrolytes (<i>Related to compromised excretion; renal function</i>)	Increased BUN, increased creatinine; decreased sodium, increased urine specific gravity; increased potassium; decreased sodium; decreased calcium; increased magnesium; increased phosphorus; altered uric acid	Monitor laboratory values; administer appropriate IV infusions and medications to correct altered electrolytes as ordered; collaborate with physician in consideration of dialysis as appropriate to maintain homeostasis; monitor uric acid levels
Nutrition (<i>Related to altered taste, decreased food intake, nausea, vomiting</i>)	Poor nutrition with inadequate caloric intake; progressive weight loss; decreasing muscle mass; thin, weak, and apathetic; poor skin turgor with breakdown; difficulty healing; anemic; decreased respiratory and cardiac status	Assess nutritional requirements; seek a consult with the registered dietician; use a calorie count; correlate baseline nutritional intake with medical status; consider individual and cultural food preferences; collaborate with physician, pharmacist, and clinical dietician in consideration of enteral and parenteral nutrition

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing gout and assessing kidney function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex. Especially note pain and edema in joints and great toe (caused by precipitation of sodium urates), headache, fatigue, decreased urinary output, and hypertension.
- ▶ Obtain a history of the patient's genitourinary, hepatobiliary, and musculoskeletal

- systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased uric acid levels may be associated with the formation of kidney stones. Educate the patient, if appropriate, on the importance of drinking a sufficient amount of water when kidney stones are suspected.
- ▶ **Nutritional Considerations:** Increased uric acid levels may be associated with gout. Nutritional therapy may be appropriate for some patients identified as having gout. Educate the patient that foods high in oxalic acid include caffeinated beverages, raw blackberries, gooseberries and plums, whole-wheat bread, beets, carrots, beans, rhubarb, spinach, dry cocoa, and Ovaltine. Foods high in purines include organ meats, which should be restricted. In other cases, the requesting HCP may not prescribe a low-purine or purine-restricted diet for treatment of

- gout because medications can control the condition easily and effectively.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Discuss lifestyle alterations that may improve health.
- ▶ Provide written and verbal information on the anatomy and physiology of the disease process.

Expected Patient Outcomes:**Knowledge**

- ▶ States understanding of the importance of recognizing and reporting disease signs and symptoms to HCP
- ▶ Verbalizes food selections that are appropriate to health maintenance

Skills

- ▶ Demonstrates proficiency in performing and recording daily weight
- ▶ Demonstrates proficiency in self-administration of medication for gout after meals as appropriate

Attitude

- ▶ Expresses willingness to make necessary lifestyle changes to improve health management
- ▶ Complies with the recommended therapeutic plan of care

RELATED MONOGRAPHS:

- ▶ Related tests include arthroscopy, biopsy bone marrow, calcium, calculus kidney stone panel, cholesterol, collagen cross-linked telopeptide, CBC, CBC RBC count, CBC RBC indices, CBC RBC morphology, creatinine, creatinine clearance, gastrin stimulation,

G6PD, lactic acid, lead, PTH, parathyroid scan, phosphorus, sickle cell screen, synovial fluid analysis, UA, US abdomen, and uric acid urine.

Refer to the Genitourinary, Hepatobiliary, and Musculoskeletal systems tables at the end of the book for related tests by body system.

Uric Acid, Urine

SYNONYM/ACRONYM: Urine urate.

COMMON USE: To assist in confirming a diagnosis of gout, assess renal function, evaluate for genetic defects related to uric acid levels, and monitor the effectiveness of therapeutic interventions.

SPECIMEN: Urine (5 mL) from a random or timed specimen collected in a clean plastic, unrefrigerated collection container. Sodium hydroxide preservative may be recommended to prevent precipitation of urates.

NORMAL FINDINGS: (Method: Spectrophotometry)

Gender	Conventional Units	SI Units (Conventional Units × 0.0059)
Male	250–800 mg/24 hr	1.48–4.72 mmol/24 hr
Female	250–750 mg/24 hr	1.48–4.43 mmol/24 hr

Values reflect average purine diet.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Disorders associated with impaired renal tubular absorption, such as Fanconi's syndrome and Wilson's disease
- Disorders of purine metabolism
- Excessive dietary intake of purines
- Gout
- Neoplastic disorders, such as leukemia, lymphosarcoma, and multiple myeloma (*related to increased cell turnover*)
- Pernicious anemia (*related to increased cell turnover*)

- Polycythemia vera (*related to increased cell turnover*)
- Renal calculus formation (*related to increased urinary excretion*)
- Sickle cell anemia (*related to increased cell turnover*)

Decreased in

- Chronic alcohol ingestion (*related to decreased excretion*)
- Hypertension (*related to decreased excretion*)
- Severe renal damage (*possibly resulting from chronic glomerulonephritis, collagen disorders, diabetic glomerulosclerosis, lactic acidosis, ketoacidosis, or alcohol abuse*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Urinalysis

SYNONYM/ACRONYM: UA.

COMMON USE: To screen urine for multiple substances such as infection, blood, sugar, bilirubin, urobilinogen, nitrates, and protein to assist in diagnosing disorders such as renal and liver disease as well as assess hydration status.

SPECIMEN: Urine (15 mL) from an unpreserved, random specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Macroscopic evaluation by dipstick and microscopic examination) Urinalysis comprises a battery of tests including a description of the color and appearance of urine; measurement of specific gravity and pH; and semiquantitative measurement of protein, glucose, ketones, urobilinogen, bilirubin, hemoglobin, nitrites, and leukocyte esterase. Urine sediment may also be examined for the presence of crystals, casts, renal epithelial cells, transitional epithelial cells, squamous epithelial cells, white blood cells (WBCs), red blood cells (RBCs), bacteria, yeast, sperm, and any other substances excreted in the urine that may have clinical significance. Examination of urine sediment is performed microscopically under high power, and results are reported as the number seen per high-power field (hpf). The color of normal urine ranges from light yellow to deep amber. The color depends on the patient's state of hydration (more concentrated samples are darker in color), diet, medication regimen, and exposure to other substances that may contribute to unusual color or odor. The appearance of normal urine is clear. Cloudiness is sometimes attributable to the presence of amorphous phosphates or urates as well as blood, WBCs, fat, or bacteria. Normal specific gravity is 1.001 to 1.029.

Dipstick

pH	5–9
Protein	Less than 20 mg/dL
Glucose	Negative
Ketones	Negative
Hemoglobin	Negative
Bilirubin	Negative
Urobilinogen	Up to 1 mg/dL
Nitrite	Negative
Leukocyte esterase	Negative
Specific gravity	1.001–1.029

Microscopic Examination

Red blood cells	Less than 5/hpf
White blood cells	Less than 5/hpf
Renal cells	None seen
Transitional cells	None seen
Squamous cells	Rare; usually no clinical significance
Casts	Rare hyaline; otherwise, none seen
Crystals in acid urine	Uric acid, calcium oxalate, amorphous urates
Crystals in alkaline urine	Triple phosphate, calcium phosphate, ammonium biurate, calcium carbonate, amorphous phosphates
Bacteria, yeast, parasites	None seen

DESCRIPTION: Routine urinalysis, one of the most widely ordered laboratory procedures, is used for basic screening purposes. It is a group of tests that evaluate the kidneys' ability to selectively excrete and reabsorb substances while maintaining proper water balance. The results can provide valuable information regarding the overall health of the patient and the patient's response to disease and treatment. The urine dipstick has a number of pads on it to indicate various biochemical markers. Urine pH is an indication of the kidneys' ability to help maintain balanced hydrogen ion concentration in the blood. Specific gravity is a reflection of the concentration ability of the kidneys. Urine protein is the most common indicator of renal disease, although there are conditions that can cause benign proteinuria. Glucose is used as an indicator of diabetes. The presence of ketones indicates impaired carbohydrate metabolism. Hemoglobin indicates the presence of blood, which is associated with renal disease. Bilirubin is used to assist in the detection of liver disorders.

Urobilinogen indicates hepatic or hematopoietic conditions. Nitrites and leukocytes are used to test for bacteriuria and other sources of urinary tract infections (UTIs). Most laboratories have established criteria for the microscopic examination of urine based on patient population (e.g., pediatric, oncology, urology), unusual appearance, and biochemical reactions.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine the presence of a genitourinary infection or abnormality
- Monitor the effects of physical or emotional stress
- Monitor fluid imbalances or treatment for fluid imbalances
- Monitor the response to drug therapy and evaluate undesired reactions to drugs that may impair renal function
- Provide screening as part of a general physical examination, especially on admission to a health-care facility or before surgery

POTENTIAL DIAGNOSIS

Unusual Color

Color	Presence of
Deep yellow	Riboflavin
Orange	Bilirubin, chrysophanic acid, phenazopyridine, santonin
Pink	Beet pigment, hemoglobin, myoglobin, porphyrin, rhubarb
Red	Beet pigment, hemoglobin, myoglobin, porphyrin, uroerythrin
Green	Oxidized bilirubin, Clorets (breath mint)
Blue	Diagnex, indican, methylene blue
Brown	Bilirubin, hematin, methemoglobin, metronidazole, nitrofurantoin, metabolites of rhubarb, senna
Black	Homogentisic acid, melanin
Smoky	Red blood cells

Test	Increased in	Decreased in
pH	Ingestion of citrus fruits Vegetarian diets Metabolic and respiratory alkalosis	Ingestion of cranberries High-protein diets Metabolic or respiratory acidosis
Protein	Benign proteinuria owing to stress, physical exercise, exposure to cold, or standing Diabetic nephropathy Glomerulonephritis Nephrosis Toxemia of pregnancy	N/A
Glucose	Diabetes	N/A
Ketones	Diabetes Fasting Fever High-protein diets Isopropanol intoxication Postanesthesia period Starvation Vomiting	N/A
Hemoglobin	Diseases of the bladder Exercise (march hemoglobinuria) Glomerulonephritis Hemolytic anemia or other causes of hemolysis (e.g., drugs, parasites, transfusion reaction) Malignancy Menstruation Paroxysmal cold hemoglobinuria	N/A

Test	Increased in	Decreased in
Urobilinogen	Paroxysmal nocturnal hemoglobinuria	
	Pyelonephritis	
	Snake or spider bites	
	Trauma	
	Tuberculosis	
	Urinary tract infections	
	Urolithiasis	
	Cirrhosis	Antibiotic therapy (suppresses normal intestinal flora)
	Heart failure	Obstruction of the bile duct
	Hemolytic anemia	
Bilirubin	Hepatitis	
	Infectious mononucleosis	
	Malaria	
	Pernicious anemia	
Nitrites	Cirrhosis	N/A
	Hepatic tumor	
	Hepatitis	
Leukocyte esterase	Presence of nitrite-forming bacteria (e.g., <i>Citrobacter</i> , <i>Enterobacter</i> , <i>Escherichia coli</i> , <i>Klebsiella</i> , <i>Proteus</i> , <i>Pseudomonas</i> , <i>Salmonella</i> , and some species of <i>Staphylococcus</i>)	N/A
	Bacterial infection	
Specific gravity	Calculus formation	
	Fungal or parasitic infection	
	Glomerulonephritis	
	Interstitial nephritis	
	Tumor	
	Adrenal insufficiency	Diuresis
	Congestive heart failure	Excess IV fluids
	Dehydration	Excess hydration
	Diabetes	Hypothermia
	Diarrhea	Impaired renal concentrating ability
Fever		
Proteinuria		
Sweating		
Vomiting		
Water restriction		
X-ray dyes		

Formed Elements in Urine Sediment

Cellular Elements

- Clue cells (cell wall of the bacteria causes adhesion to epithelial cells) are present in nonspecific vaginitis

caused by *Gardnerella vaginitis*, *Mobiluncus cortisii*, and *M. mulieris*.

- RBCs are present in glomerulonephritis, lupus nephritis, focal glomerulonephritis, calculus, malignancy,

- infection, tuberculosis, infarction, renal vein thrombosis, trauma, hydro-nephrosis, polycystic kidney, urinary tract disease, prostatitis, pyelonephritis, appendicitis, salpingitis, diverticulitis, gout, scurvy, subacute bacterial endocarditis, infectious mononucleosis, hemoglobinopathies, coagulation disorders, heart failure, and malaria.
- Renal cells that have absorbed cholesterol and triglycerides are also known as oval fat bodies.
 - Renal cells come from the lining of the collecting ducts, and increased numbers indicate acute tubular damage as seen in acute tubular necrosis, pyelonephritis, malignant nephrosclerosis, acute glomerulonephritis, acute drug or substance (salicylate, lead, or ethylene glycol) intoxication, or chemotherapy, resulting in desquamation, urolithiasis, and kidney transplant rejection.
 - Squamous cells line the vagina and distal portion of the urethra. The presence of normal squamous epithelial cells in female urine is generally of no clinical significance. Abnormal cells with enlarged nuclei indicate the need for cytological studies to rule out malignancy.
 - Transitional cells line the renal pelvis, ureter, bladder, and proximal portion of the urethra. Increased numbers are seen with infection, trauma, and malignancy.
 - WBCs are present in acute UTI, tubulointerstitial nephritis, lupus nephritis, pyelonephritis, kidney transplant rejection, fever, and strenuous exercise.

Casts

- Granular casts are formed from protein or by the decomposition of cellular elements. They may be seen in renal disease, viral infections, or lead intoxication.
- Large numbers of hyaline casts may be seen in renal diseases, hypertension, congestive heart failure, or nephrotic

syndrome and in more benign conditions such as fever, exposure to cold temperatures, exercise, or diuretic use.

- RBC casts may be found in acute glomerulonephritis, lupus nephritis, and subacute bacterial endocarditis.
- Waxy casts are seen in chronic renal failure or conditions such as kidney transplant rejection, in which there is renal stasis.
- WBC casts may be seen in lupus nephritis, acute glomerulonephritis, interstitial nephritis, and acute pyelonephritis.

Crystals

- Crystals found in freshly voided urine have more clinical significance than crystals seen in a urine sample that has been standing for more than 2 to 4 hr.
- Calcium oxalate crystals are found in ethylene glycol poisoning, urolithiasis, high dietary intake of oxalates, and Crohn's disease.
- Cystine crystals are seen in patients with cystinosis or cystinuria.
- Leucine or tyrosine crystals may be seen in patients with severe liver disease.
- Large numbers of uric acid crystals are seen in patients with urolithiasis, gout, high dietary intake of foods rich in purines, or who are receiving chemotherapy (see monograph titled "Uric Acid, Urine").

Yeast

- Yeast cells, usually *Candida albicans* may be seen in diabetes and vaginal moniliasis.

CRITICAL FINDINGS

Possible critical values are the presence of uric acid, cystine, leucine, or tyrosine crystals.

The combination of grossly elevated urine glucose and ketones is also considered significant.

It is essential that a critical finding be communicated immediately to the

requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Certain foods, such as onion, garlic, and asparagus, contain substances that may give urine an unusual odor. An ammonia-like odor may be produced by the presence of bacteria. Urine with a maple syrup-like odor may indicate a congenital metabolic defect (maple syrup urine disease).
- The various biochemical strips are subject to interference that may produce false-positive or false-negative results. Consult the laboratory for specific information regarding limitations of the method in use and a listing of interfering drugs.
- The dipstick method for protein detection is mostly sensitive to the presence of albumin; light-chain or Bence Jones proteins may not be detected by this method. Alkaline pH may produce false-positive protein results.
- Large amounts of ketones or ascorbic acid may produce false-negative or decreased color development on

the glucose pad. Contamination of the collection container or specimen with chlorine, sodium hypochlorite, or peroxide may cause false-positive glucose results.

- False-positive ketone results may be produced in the presence of ascorbic acid, levodopa metabolites, valproic acid, phenazopyridine, phenylketones, or phthaleins.
- The hemoglobin pad may detect myoglobin, intact RBCs, and free hemoglobin. Contamination of the collection container or specimen with sodium hypochlorite or iodine may cause false-positive hemoglobin results. Negative or decreased hemoglobin results may occur in the presence of formalin, elevated protein, nitrite, ascorbic acid, or high specific gravity.
- False-negative nitrite results are common. Negative or decreased results may be seen in the presence of ascorbic acid and high specific gravity. Other causes of false-negative values relate to the amount of time the urine was in the bladder before voiding or the presence of pathogenic organisms that do not reduce nitrates to nitrites.
- False-positive leukocyte esterase reactions result from specimens contaminated by vaginal secretions. The presence of high glucose, protein, or ascorbic acid concentrations may cause false-negative results. Specimens with high specific gravity may also produce false-negative results. Patients with neutropenia (e.g., oncology patients) may also have false-negative results because they do not produce enough WBCs to exceed the sensitivity of the biochemical reaction.
- Specimens that cannot be delivered to the laboratory or tested within 1 hr should be refrigerated or should have a preservative added that is recommended by the laboratory. Specimens collected more

than 2 hr before submission may be rejected for analysis.

- Because changes in the urine specimen occur over time, prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Changes that may occur over time include: Production of a stronger odor and an increase in pH (bacteria in the urine break urea down to ammonia)

- A decrease in clarity (as bacterial growth proceeds or precipitates form)
- A decrease in bilirubin and urobilinogen (oxidation to biliverdin and urobilin)
- A decrease in ketones (lost through volatilization)
- Decreased glucose (consumed by bacteria)
- An increase in bacteria (growth over time)
- Disintegration of casts, WBCs, and RBCs
- An increase in nitrite (overgrowth of bacteria)

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fluid volume <i>(Related to hypovolemia associated with body fluid shifts to third space, body fluid loss, reduced oral intake; increased perspiration; diaphoresis; gastrointestinal [GI] tract loss from vomiting, diarrhea; overly aggressive diuresis)</i>	Deficient: decreased urinary output, fatigue, sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status	Record daily weight and monitor trends; record accurate intake and output; collaborate with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes as ordered
Confusion <i>(Related to an alteration in fluid and electrolytes secondary to hepatic disease and encephalopathy; acute alcohol</i>	Disorganized thinking, restlessness, irritability, altered concentration and attention span, changeable mental function over the day, hallucinations; altered attention span; inability to	Treat the medical condition; correlate confusion with the need to reverse altered electrolytes; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or restraints; consider pharmacological interventions; record accurate intake and output to assess fluid status;

Problem	Signs & Symptoms	Interventions
consumption; hepatic metabolic insufficiency)	follow directions; disoriented to person, place, time, and purpose; inappropriate affect	monitor blood ammonia level; determine last alcohol use; assess for symptoms of hepatic encephalopathy such as confusion, sleep disturbances, incoherence; protect the patient from physical harm; administer lactulose as prescribed
Self-care (Related to altered mental status; fatigue; weakness; secondary to renal insufficiency, hepatic disease, hypovolemia, dehydration)	Difficulty fastening clothing; difficulty performing personal hygiene; unable to maintain appropriate appearance; difficulty with independent mobility	Reinforce self-care techniques as taught by occupational therapy; ensure the patient has adequate time to perform self- care; encourage use of assistive devices to maintain independence
Renal function (Related to renal ischemia associated with shock, sepsis, hypovolemia; postoperative injury; trauma; nephrotoxic drugs [aminogly- coside, heavy metals, radiographic contrast]; renal vascular occlusion; hemolytic transfusion reaction; decreased cardiac output; tubular necrosis; obstruction; tumor;	Increased BUN; increased creatinine; decreased creatinine clearance; increased urine specific gravity (greater than 1.029); hematuria; proteinuria; decreased urine output less than 400 mL/day (with adequate intake and no fluid loss); weight gain; elevated potassium; elevated phosphate; decreased calcium; decreased sodium; increased magnesium; metabolic acidosis; decreased HGB/ HCT	Monitor, record, and trend intake and output; monitor urine specific gravity; monitor and trend renal specific urine and blood studies, BUN, creatinine, sodium, potassium, magnesium, pH, urinalysis, HGB/HCT; monitor and trend weight daily; assess and monitor for edema, JVD, hypertension, adventitious breath sounds, impaired gas exchange; use pulse oximetry; administer prescribed oxygen; administer prescribed hemodialysis; administer prescribed medications (diuretics); administer prescribed fluids; consider renal function with antibiotic administration

(table continues on page 1568)

medications
[NSAID, ACE,
immuno-
suppressants,
anti-
neoplastics,
antifungals])

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for disease, infection, and inflammation and evaluate for dehydration.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine, genitourinary, immune, hematopoietic, and hepatobiliary systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. If a catheterized specimen is to be collected, explain this procedure to the patient, and obtain a catheterization tray. Address concerns about pain and explain that there should be no discomfort during the procedure. Inform the patient that specimen collection takes approximately 5 to 10 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

Random Specimen (Collect in Early Morning)

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Pediatric Urine Collector

- ▶ Put on gloves. Appropriately cleanse the genital area, and allow the area to dry. Remove the covering over the adhesive strips on the collector bag, and apply the bag over the genital area. Diaper the child. When specimen is obtained, place the entire collection bag in a sterile urine container.

Indwelling Catheter

- ▶ Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen

port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Urinary Catheterization

- Place female patient in lithotomy position or male patient in supine position. Using sterile technique, open the straight urinary catheterization kit and perform urinary catheterization. Place the retained urine in a sterile specimen container.

Suprapubic Aspiration

- Place the patient in a supine position. Cleanse the area with antiseptic and drape with sterile drapes. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container.
- Perform catheterization through the stoma. Do not collect urine from the pouch from the patient with a urinary diversion (e.g., ileal conduit).

General

- Include on the collection container's label whether the specimen is clean catch or catheter and any medications that may interfere with test results.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to report symptoms such as pain related to tissue inflammation, pain or irritation during void, bladder spasms, or alterations in urinary elimination.
- Observe/assess for signs of inflammation if the specimen is obtained by suprapubic aspiration.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications

of the test results, as appropriate. Instruct the patient with a UTI, as appropriate, on the proper technique for wiping the perineal area (front to back) after a bowel movement. UTIs are more common in women who use diaphragm/spermicide contraception. These patients can be educated, as appropriate, in the proper insertion and removal of the contraceptive device to avoid recurrent UTIs.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- Instruct the patient to begin antibiotic therapy, as prescribed, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if symptoms are no longer present.
- Answer any questions or address any concerns voiced by the patient or family.
- Teach the patient to save urine for accurate measurement and evaluation of characteristics.

Expected Patient Outcomes:

Knowledge

- States symptoms of fluid overload, headache, tachycardia, shortness of breath, and understands to report symptoms to HCP
- States fluid preferences and identifies selections for fluid replacement

Skills

- Proficiently describes normal urine characteristics and identifies concerns that should be reported to HCP
- Demonstrates proficiency in recording intake and measuring and recording urine output

Attitude

- Complies with recommended medication regime

Complies with follow-up appointment schedule to monitor renal and urinary function

RELATED MONOGRAPHS:

Related tests include amino acids, angiography renal, antibodies, anti-glomerular basement membrane, biopsy bladder, biopsy kidney, bladder cancer marker, BUN, calcium, calculus kidney stone panel, CBC, creatinine, culture urine, cystometry, cystoscopy, cystourethrography

voiding, cytology urine, electrolytes, glucose, glycated hemoglobin, IFE, IVP, ketones, KUB study, microalbumin, osmolality, oxalate, protein total, phosphorus, renogram, retrograde ureteropyelography, urea nitrogen urine, uric acid (blood and urine), and US abdomen. Refer to the Endocrine, Genitourinary, Immune, Hematopoietic, and Hepatobiliary systems tables at the end of the book for related tests by body system.

Uterine Fibroid Embolization

SYNONYM/ACRONYM: UFE; uterine artery embolization.

COMMON USE: A less invasive modality used to assist in treating fibroid tumors found in the uterine lining, heavy menstrual bleeding, and pelvic pain.

AREA OF APPLICATION: Uterus.

CONTRAST: IV iodine based.

DESCRIPTION: Uterine fibroid embolization (UFE) is a way of treating fibroid tumors of the uterus. Fibroid tumors, also known as myomas, are masses of fibrous and muscle tissue in the uterine wall that are benign but that may cause heavy menstrual bleeding, pain in the pelvic region, or pressure on the bladder or bowel. Using angiographic methods, a catheter is placed in each of the two uterine arteries, and small particles are injected to block the arterial branches that supply blood to the fibroids. The fibroid tissue dies, the mass shrinks, and the symptoms are relieved. This procedure, which is done under local anesthesia, is less invasive than open surgery done to remove uterine

fibroids. Because the effects of uterine fibroid embolization on fertility are not yet known, the ideal candidate is a premenopausal woman with symptoms from fibroid tumors who no longer wishes to become pregnant. This technique is an alternative for women who do not want to receive blood transfusions or do not wish to receive general anesthesia. This procedure may be used to halt severe bleeding following childbirth or caused by gynecological tumors.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a

procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure.**
- ◆ Patients with bleeding disorders **because the puncture site may not stop bleeding.**
- ◆ Patients in whom cancer is a possibility or who have inflammation or infection in the pelvis.

INDICATIONS

- Treatment for anemia from chronic blood loss
- Treatment of fibroid tumors and tumor vascularity, for both single and multiple tumors
- Treatment of tumors in lieu of surgical resection

POTENTIAL DIAGNOSIS

Normal findings in

- Decrease in uterine bleeding
- Decrease of pelvic pain or fullness

Abnormal findings in

- No reduction in size of fibroid

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger

patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- A small percentage of women may pass a small piece of fibroid tissue after the procedure. Women with this problem may require a procedure called a D & C (dilatation and curettage).
- Some women may experience menopause shortly after the procedure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing and treating the uterus.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Note any recent procedures that can interfere with test results; include examinations utilizing barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Explain that a sedative and/or anesthetic may be administered before the procedure to promote relaxation. Inform the patient that the procedure is performed in a radiology or vascular department by an HCP, with support staff, and takes approximately 30 to 120 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.

- ▶ Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Instruct the patient to avoid taking anti-coagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

INTRATEST:

Potential Complications:

Establishing an IV site and injecting contrast medium by catheter are invasive procedures. Complications are rare but do include risk for allergic reaction (**related to contrast reaction**); bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners; postprocedural bleeding from the site is rare because at the conclusion of the procedure a resorbable device, composed of non-latex-containing arterial anchor, collagen plug, and suture, is deployed to seal the puncture site**); blood clot formation (**related to thrombus formation on the tip of the catheter sheath surface or in the lumen of the catheter; the use of a heparinized saline flush during the procedure decreases the risk of emboli**); cardiac arrhythmias; hematoma (**related to blood leakage into the tissue following insertion of the catheter**); infection (**which might occur if bacteria from the skin surface is introduced during**

- catheter insertion**); tissue damage (**related to extravasation of the contrast during injection**); nerve injury or damage to a nearby organ (**which might occur if the catheter strikes a nerve or perforates an organ**); detachment of small pieces of fibroid tissue during UFE which will pass, but a D & C may be required to verify that all material is removed to prevent further bleeding or infection; and the occurrence of menopause following UFE, which is generally experienced in women older than 45 yr of age.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
 - ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
 - ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use non-ionic contrast medium for the procedure.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Have emergency equipment readily available.
 - ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
 - ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
 - ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
 - ▶ Administer an anti-anxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to an uncooperative adult, as ordered.
 - ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.

- ▶ Using a pen, mark the site of the patient's peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- ▶ Place the patient in the supine position on an examination table. Cleanse the selected area, and cover with a sterile drape.
- ▶ The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.
- ▶ Ask the patient to inhale deeply and hold her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- ▶ Particles are injected through the catheter to block the blood flow to the fibroids. The particles include polyvinyl alcohol, gelatin sponge (Gelfoam), and microspheres.
- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Inform the patient that she may experience pelvic cramps for several days after the procedure and possible mild nausea and fever.
- ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to genitourinary system. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Monitor intake and
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage her to review corresponding literature provided by a pharmacist.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include CBC, CT angiography, CT pelvis, hysterosalpingography, laparoscopy, MRA, MRI pelvis, PT/INR, and US pelvis.
- Refer to the Reproductive System table at the end of the book for related tests by body system.

Vanillylmandelic Acid, Urine

SYNONYM/ACRONYM: VMA.

COMMON USE: To assist in the diagnosis and follow up treatment of pheochromocytoma, neuroblastoma, and ganglioblastoma. This test can also be useful in evaluation and follow-up of hypertension.

SPECIMEN: Urine (25 mL) from a timed specimen collected in a clean plastic collection container with 6N hydrochloric acid as a preservative.

NORMAL FINDINGS: (Method: High-pressure liquid chromatography)

Age	Conventional Units	SI Units (Conventional Units × 5.05)
3–6 yr	1–2.6 mg/24 hr	5–13 micromol/24 hr
7–10 yr	2–3.2 mg/24 hr	10–16 micromol/24 hr
11–16 yr	2.3–5.2 mg/24 hr	12–26 micromol/24 hr
17–83 yr	1.4–6.5 mg/24 hr	7–33 micromol/24 hr

DESCRIPTION: Vanillylmandelic acid (VMA) is a major metabolite of epinephrine and norepinephrine. It is elevated in conditions that also are marked by over production of catecholamines. Creatinine is usually measured simultaneously to ensure adequate collection and to calculate an excretion ratio of metabolite to creatinine.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of neuroblastoma, ganglioneuroma, or pheochromocytoma
- Evaluate hypertension of unknown cause

POTENTIAL DIAGNOSIS

Increased in
Catecholamine-secreting tumors will cause an increase in VMA.

- Ganglioneuroma
- Hypertension secondary to pheochromocytoma

- Neuroblastoma
- Pheochromocytoma

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase VMA levels include ajmaline, chlorpromazine, glucagon, guaifenesin, guanethidine, isoproterenol, methyl dopa, nitroglycerin, oxytetracycline, phenazopyridine, phenolsulfonphthalein, prochlorperazine, rauwolfia, reserpine, sulfobromophthalein, and syrosingopine.
- Drugs that may decrease VMA levels include brofaromine, guanethidine, guanfacine, imipramine, isocarboxazid, methyl dopa, monoamine oxidase inhibitors, morphine, nialamide (in patients with schizophrania), and reserpine.
- Stress, hypoglycemia, hyperthyroidism, strenuous exercise, smoking, and drugs can produce elevated catecholamines.
- Recent radioactive scans within 1 wk of the test can interfere with test results.

- Failure to collect all urine and store 24-hr specimen properly will result in a falsely low result.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating or the presence of tumors.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent

contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

- ▶ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.
- ▶ Note that there are no fluid restrictions unless by medical direction.
- ▶ Instruct the patient to abstain from smoking tobacco for 24 hr before testing.
- ▶ Inform the patient of the following dietary, medication, and activity restrictions in preparation for the test (protocols may vary among facilities):
- ▶ The patient should not consume foods high in amines for 48 hr before testing (bananas, avocados, beer, aged cheese, chocolate, cocoa, coffee, fava beans, grains, tea, vanilla, walnuts, and red wine).
- ▶ The patient should not consume foods or fluids high in caffeine for 48 hr before testing (coffee, tea, cocoa, and chocolate).
- ▶ The patient should not consume any foods or fluids containing vanilla or licorice.
- ▶ The patient should avoid self-prescribed medications (especially aspirin) and prescribed medications (especially pyridoxine, levodopa, amoxicillin, carbidopa, reserpine, and disulfiram) for 2 wk before testing and as directed.
- ▶ The patient should avoid excessive exercise and stress during the 24-hr collection of urine.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary, medication, and activity restrictions and pretesting preparations prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

Timed Specimen

- ▶ Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- ▶ Begin the test between 6 and 8 a.m. if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- ▶ Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ **Nutritional Considerations:** Instruct the patient to avoid foods or drinks containing caffeine. Over-the-counter medications should be taken only under the advice of the patient's HCP.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography adrenal, calcium, catecholamines, CT renal, homovanillic acid, metanephrines, and renin.
- ▶ Related to Endocrine System table at the end of the book for related tests by body system.

Varicella Antibodies

SYNONYM/ACRONYM: Varicella-zoster antibodies, chickenpox, VZ.

COMMON USE: To assist in diagnosing chickenpox or shingles related to a varicella-zoster infection and to assess for immunity.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Enzyme immunoassay)

	IgM	Interpretation	IgG	Interpretation
Negative	0.89 index or less	No significant level of detectable antibody	0.89 index or less	No significant level of detectable antibody; indicative of nonimmunity
Indeterminate	0.9–1.0 index	Equivocal results; retest in 10–14 d	0.9–1.0 index	Equivocal results; retest in 10–14 d
Positive	1.1 index or greater	Antibody detected; indicative of recent immunization, current or recent infection	1.1 index or greater	Antibody detected; indicative of immunization, current or past infection

DESCRIPTION: Varicella-zoster is a double-stranded DNA herpes virus that is responsible for two clinical syndromes: chickenpox and shingles. The incubation period for varicella infection is 2 to 3 wk, and it is highly contagious for about 2 wk beginning 2 days before a rash develops. It is transmitted in respiratory secretions and by direct contact with the secretions inside. Painful eruptions appear on the

skin and mucus membranes. The primary exposure to the highly contagious virus usually occurs in susceptible school-age children. Adults without prior exposure and who become infected may have severe complications, including pneumonia. Neonatal infection from the mother is possible if exposure occurs during the last 3 wk of gestation. The second syndrome, shingles, results when the presumably

latent virus is reactivated and produces painful skin eruptions along nerve tracks. In both syndromes, the presence of immunoglobulin (Ig) M antibodies indicates acute infection and the presence of IgG antibodies indicates current or past infection. A reactive varicella antibody result indicates immunity but does not protect an individual from shingles. There are also polymerase chain reaction methods that can detect varicella-zoster DNA in various specimen types.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine susceptibility or immunity to chickenpox

POTENTIAL DIAGNOSIS

Positive findings in

- Varicella infection

Negative findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to altered nerve root function secondary to viral infection</i>)	Pain that is burning, stabbing, tearing	Keep clothing or bedding from touching the effected area; use a foot cradle as appropriate; assess and monitor the location, duration, and characteristics of pain; explain the importance of pain medication and administer as prescribed; teach how to apply antipruritic lotion (e.g., calamine); discuss the application of wet compresses to decrease itching; consider the use of distraction and relaxation techniques as a pain management modality
Infection (<i>Related to exposure to Varicella zoster</i>)	Headache; fever; malaise; blister rash; chills; nausea; pain and tingling at area of rash before appearance; itching; open sores; loss of appetite	Encourage vaccination of all at-risk family members or friends; administer prescribed antiviral medication; monitor and trend white blood cell count; monitor and trend temperature; decrease exposure to noninfected individuals by limiting visitors; prevent exposure to others from cough or touching infected fluids; practice vigilant hand washing; keep infected individuals home

Problem	Signs & Symptoms	Interventions
Skin (<i>Related to itching secondary to varicella infection</i>)	Scratching with open sores; drainage from open sores	Teach how to decrease the itch-scratch cycle (use warm water and pat dry rather than rub); administer prescribed antipruritic creams or lotion
Fluid volume (<i>Related to inadequate fluid intake secondary to nausea and altered appetite associated with varicella infection</i>)	Hypotension; decreased cardiac output; decreased urinary output; dry skin/mucous membranes; poor skin turgor; sunken eyeballs; increased urine specific gravity; hemoconcentration	Monitor intake and output; assess for symptoms of dehydration (dry skin, dry mucous membranes, poor skin turgor, sunken eyeballs); monitor and trend vital signs; monitor for symptoms of poor cardiac output (rapid, weak, thready pulse); record daily weight with monitoring of trends; collaborate with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, hematocrit, sodium); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes as ordered

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for a viral infection or immunity.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of exposure to varicella.
- ▶ Obtain a history of the patient's immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional

- supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in detectable level of antibody. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Vaccination Considerations:** Record the date of last menstrual period and determine the possibility of pregnancy prior to administration of varicella vaccine to female varicella-nonimmune patients. Instruct patient not to become pregnant for 1 mo after being vaccinated with the varicella vaccine to protect any fetus from contracting the disease and having serious birth defects. Instruct on birth control methods to prevent pregnancy, if appropriate.
- ▶ Recognize anxiety related to test results, and provide emotional support if results are positive and the patient is pregnant. Inform the patient with shingles about access to pain management. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Educate the patient regarding access to counseling services.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Instruct the patient in isolation precautions during the time of communicability or contagion.
- ▶ Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Provide information regarding vaccine-preventable diseases where indicated (e.g., varicella).
- ▶ Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac).
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:**Knowledge**

- ▶ States importance of taking prescribed antiviral in its entirety to treat infection
- ▶ States the importance of good hand washing to prevent disease transmission to others

Skills

- ▶ Demonstrates proficiency in the application of antipruritic lotion
- ▶ Demonstrates proficiency in taking and recording temperature

Attitude

- ▶ Complies with the request to remain home to prevent spread of the varicella virus until no longer contagious
- ▶ Complies with the request to increase oral fluid intake to decrease dehydration risk

RELATED MONOGRAPHS:

- ▶ Refer to the Immune and Reproductive systems tables at the end of the book for related tests by body system.

Venography, Lower Extremity Studies

SYNONYM/ACRONYM: Lower limb venography, phlebography, venogram.

COMMON USE: To visualize and assess the venous vasculature in the lower extremities related to diagnosis of deep vein thrombosis and congenital anomalies.

AREA OF APPLICATION: Veins of the lower extremities.

CONTRAST: IV iodine based.

DESCRIPTION: Venography allows x-ray visualization of the venous vasculature system of the extremities after injection of an iodinated contrast medium. Lower extremity studies identify and locate thrombi within the venous system of the lower limbs. After injection of the contrast medium, x-ray images are taken at timed intervals. Usually both extremities are studied, and the unaffected side is used for comparison with the side suspected of having deep vein thrombosis (DVT) or other venous abnormalities, such as congenital malformations or incompetent valves. Thrombus formation usually occurs in the deep calf veins and at the venous junction and its valves. If DVT is not treated, it can lead to femoral and iliac venous occlusion, or the thrombus can become an embolus, causing a pulmonary embolism. Venography is accurate for identifying thrombi in veins below the knee.

This procedure is contraindicated for:

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of non-ionic contrast or an alternative non-contrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) because iodinated contrast is nephrotoxic.

-  Elderly and compromised patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
-  Patients with bleeding disorders because the puncture site may not stop bleeding.
-  Patients with severe edema of the legs in whom venous access is not possible.

INDICATIONS

- Assess deep vein valvular competence
- Confirm a diagnosis of DVT
- Determine the cause of extremity swelling or pain
- Determine the source of emboli when pulmonary embolism is suspected or diagnosed
- Distinguish clot formation from venous obstruction
- Evaluate congenital venous malformations
- Locate a vein for arterial bypass graft surgery

POTENTIAL DIAGNOSIS

Normal findings in

No obstruction to flow and no filling defects after injection of radiopaque contrast medium; steady opacification of superficial and deep vasculature with no filling defects

Abnormal findings in

- Deep vein valvular incompetence
- DVT
- Pulmonary embolism
- Venous obstruction

CRITICAL FINDINGS

- DVT
- Pulmonary embolism

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Movement of the leg being tested, excessive tourniquet constriction, insufficient injection of contrast medium, and delay between injection and the x-ray.
- Severe edema of the legs, making venous access impossible.

Other considerations

- Improper injection of the contrast medium that allows it to seep deep into the muscle tissue.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
- Consultation with a HCP should occur before the procedure for radiation safety concerns regarding

younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the veins in the lower extremities.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Obtain a history of the patient's cardiovascular and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants,

aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain to the patient that there may be moments of discomfort and some pain experienced during the procedure. Inform the patient that the procedure is usually performed in a radiology or vascular suite by an HCP, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.
- ▶ Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

INTRATEST:

Potential Complications:

- Complications include allergic reaction to the contrast medium, venous thrombophlebitis **that is caused by contrast**, venous embolism **related to dislodgement of a deep-vein clot**, and cellulitis or pain **related to infiltration at the injection site**.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
 - ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
 - ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Have emergency equipment readily available.
 - ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
 - ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
 - ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
 - ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.
 - ▶ Using a pen, mark the site of the patient's peripheral pulses before venography; this allows for quicker and more consistent assessment of the pulses after the procedure.
 - ▶ Place the patient in the supine position on an examination table. Cleanse the selected area, and cover with a sterile drape.
 - ▶ A local anesthetic is injected at the site, and a small incision is made or a needle inserted.
 - ▶ The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined.
 - ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale.
 - ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
 - ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
 - ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
 - ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume diet, fluids, and medications, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr

for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide

teaching and information regarding the clinical implications of the test results, as appropriate.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include alveolar/arterial gradient, angiography pulmonary, antibodies anticardiolipin, antithrombin III, blood gases, CT angiography, D-dimer, FDP, lactic acid, lung perfusion scan, lung ventilation scan, MRA, MRI abdomen, MRI venography, plethysmography, PT/INR, renogram, US peripheral Doppler, and US venous Doppler extremity studies.
- ▶ Refer to the Cardiovascular and Respiratory systems tables at the end of the book for related tests by body system.

Vertebroplasty

SYNONYM/ACRONYM: None.

COMMON USE: A minimally invasive procedure to treat the spine for disorders such as tumor, lesions, osteoporosis, vertebral compression, and pain.

AREA OF APPLICATION: Spine.

CONTRAST: None.

DESCRIPTION: Vertebroplasty is a minimally invasive, nonsurgical therapy used to repair a broken vertebra and to provide relief of

pain related to vertebral compression in the spine that has been weakened by osteoporosis or tumoral lesions. Osteoporosis

affects over 10 million women in the United States and accounts for over 700,000 vertebral fractures per year. This procedure is usually successful at alleviating the pain caused by a compression fracture less than 6 mo in duration with pain directly referable to the location of the fracture. Secondary benefits may include vertebra stabilization and reduction of the risk of further compression.

Vertebroplasty involves the injection of an orthopedic cement mixture through a needle into a fracture site. The cement hardens, stabilizes the bone preventing further collapse, and reduces the pain caused by bone rubbing against bone. The injection is visualized with guidance from radiological imaging or fluoroscopy; a small amount of contrast (with or without iodine) may be used to provide imaged guidance for the injection of the cement.

Vertebroplasty may be the preferred procedure when patients are too elderly or frail to tolerate open spinal surgery or if bones are too weak for surgical repair. Patients with a malignant tumor may benefit from vertebroplasty. Other possible applications include in younger patients whose osteoporosis is caused by long-term steroid use or a metabolic disorder. This procedure is recommended after basic treatments such as bedrest and orthopedic braces have failed or when pain medication has been ineffective or caused the patient medical problems, including stomach ulcers.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a

procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

- ◆ Patients with conditions associated with adverse reactions to vertebroplasty cement.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).
Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure.**
- ◆ Patients with bleeding disorders receiving an arterial or venous puncture **because the site may not stop bleeding.**

- ◆ Patients with pain that is primarily radicular in nature.
- ◆ Patients with pain that is improving or that has been present and unchanged for years.
- ◆ Patients who have undergone imaging procedures that suggest no fracture is present or that the fracture is remote from the patient's pain.

INDICATIONS

- Assist in the detection of nonmalignant tumors before surgical resection.
- Repair of compression spinal fractures of varying ages. Fractures older than 6 mo will respond but at a slower rate. Fractures less than 4 wk old should be given a chance to heal without intervention unless they are associated with disabling pain or hospitalization.
- Repair of spinal problems due to tumors.

POTENTIAL DIAGNOSIS

Normal findings in

- Improvement in the ability to ambulate without pain
- Relief of back pain

Abnormal findings in

- Failure to reduce the patient's pain
- Failure to improve the patient's mobility

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field,

which may inhibit organ visualization and cause unclear images.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status, may interfere with the test results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this procedure can assist in improving spinal cord function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, vertebroplasty cement, or sedatives.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Explain that contrast medium, if ordered, may be used to verify placement of the vertebroplasty cement. Inform the patient that the procedure is usually performed in the radiology department by an HCP, with support staff, and takes approximately 30 to 90 min.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**
- ▶ Note that this procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

INTRATEST:

Potential Complications:

- Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to cement or contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**. Other complications related to the use of the cement include soft tissue damage and nerve impingement **related to extravasation of cement**, embolism to the lungs **related to a blood clot or cement leakage**, and respiratory and cardiac failure; risk for complications increases when more than one vertebra is treated at the same time.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
 - ▶ Ensure the patient has removed all external metallic objects from the area to be examined.

- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.

- ▶ Have emergency equipment readily available.

- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

Geriatric Considerations Elderly patients present with a variety of concerns when undergoing diagnostic procedures. Level of cooperation and fall risk may be complicated by underlying problems such as visual and hearing impairment, joint and muscle stiffness, physical weakness, mental confusion, and the effects of medications. A fall injury can be avoided by providing assistance getting on and off the x-ray table. Elderly patients are often chronically dehydrated; anticipating the effects of hypovolemia and orthostasis can also help prevent falls.

- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.

- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.

- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.

- ▶ Administer an anti-anxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

- ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.

- ▶ Place the patient in the prone position on an examination table. Cleanse the selected area, and cover with a sterile drape.

- ▶ A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy.

- ▶ Orthopedic cement is injected through the needle into the fracture.

- ▶ Ask the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale.

- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.

- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- ▶ Instruct the patient to resume diet, fluids, and medications, as directed by the HCP. Renal function should be assessed before metformin is resumed.

- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.

- ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.

- ▶ Instruct the patient in the care and assessment of the site.

- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.

- ▶ Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.

- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide

teaching and information regarding the clinical implications of the test results, as appropriate.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and

determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include bone mineral densitometry, bone scan, CT spine, EMG, and MRI musculoskeletal.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Visual Fields Test

SYNONYM/ACRONYM: Perimetry, VF.

COMMON USE: To assess visual field function related to the retina, optic nerve, and optic pathways to assist in diagnosing visual loss disorders such as brain tumors, macular degeneration, and diabetes.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: The visual field (VF) is the area within which objects can be seen by the eye as it fixes on a central point. The central field is an area extending 25° surrounding the fixation point. The peripheral field is the remainder of the area within which objects can be viewed. This test evaluates the central VF, except within the physiological blind spot, through systematic movement of the test object across a tangent screen. It tests the function of the retina, optic nerve, and optic pathways. VF testing may be performed manually by the examiner (confrontation VF examination) or by using partially or fully automated equipment (tangent screen, Goldman, Humphrey VF examination). In the manual VF test, the patient is

asked to cover one eye and fix his or her gaze on the examiner. The examiner moves his or her hand out of the patient's VF and then gradually brings it back into the patient's VF. The patient signals the examiner when the hand comes back into view. The test is repeated on the other eye. The manual test is frequently used for screening because it is quick and simple. Tangent screen or Goldman testing is an automated method commonly used to create a map of the patient's VF.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect field vision loss and evaluate its progression or regression

POTENTIAL DIAGNOSIS

Normal findings in

- Normal central vision field extends in a circle approximately 25–30° on all sides of central fixation and out 60° superiorly (upward), 60° nasally (medially), 75° inferiorly (downward), and 90° temporally (laterally). There is a normal physiological blind spot, 12° to 15° temporal to the central fixation point and approximately 1.5° below the horizontal meridian which is approximately 7.5° high and 5.5° wide. The patient should be able to see the test object throughout the entire central vision field except within the physiological blind spot.

Abnormal findings in

- Amblyopia
- Blepharochalasis
- Blurred vision
- Brain injury
- Brain tumors
- Cerebrovascular accidents
- Choroidal nevus
- Diabetes with ophthalmic manifestations
- Glaucoma
- Headache
- Macular degeneration
- Macular drusen
- Nystagmus
- Optic neuritis or neuropathy
- Ptosis of eyelid
- Retinal detachment, hole, or tear
- Retinal exudates or hemorrhage
- Retinal occlusion of the artery or vein
- Retinitis pigmentosa
- Rheumatoid arthritis
- Stroke
- Subjective visual disturbance
- Use of high-risk medications
- VF defect
- Vitreous traction syndrome

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- An uncooperative patient or a patient with severe vision loss who has difficulty seeing even a large vision screen may have test results that are invalid.
- Assess and make note of the patient's cooperation and reliability as good, fair, or poor, because it is difficult to evaluate factors such as general health, fatigue, or reaction time that affect test performance.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure assesses visual field function and vision loss.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens.
- ▶ Obtain a history of the patient's known or suspected vision loss; changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- ▶ Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Measure visual acuity with and without corrective lenses prior to testing. Instruct the patient to wear corrective lenses if appropriate and if worn to correct for distance vision. Instruct the patient regarding the importance of keeping the eyes open for the test.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that no discomfort will be

experienced during the test. Inform the patient that a health-care provider (HCP) performs the test in a quiet, darkened room and that to evaluate both eyes, the test can take up 30 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Seat the patient 3 ft away from the tangent screen with the eye being tested directly in line with the central fixation tangent, usually a white disk, on the screen. Cover the eye that is not being tested. Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. Reposition the patient as appropriate to ensure the eye(s) to be tested are properly aligned in front of the VF testing equipment. While the patient stares at the disk on the screen, the examiner moves an object toward the patient's visual field. The patient signals the examiner when the object enters his or her visual field. The patient's responses are recorded, and a map of the patient's VF, including areas of visual defect, can be drawn on paper manually or by a computer.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss, perceived

loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of the test results on the patient's lifestyle.

Provide contact information, if desired, for a general patient education Web site on the topic of eye care (e.g., www.allaboutvision.com). Provide contact information regarding vision aids, if desired, for ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research [NIDRR], available at www.abledata.com).

Information can also be obtained from the American Macular Degeneration Foundation (www.macular.org), the Glaucoma Research Foundation (www.glaucoma.org), and the American Diabetes Association (www.diabetes.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CT brain, EEG, evoked brain potentials, fluorescein angiography, fructosamine, fundus photography, glucagon, glucose, glycosylated hemoglobin, gonioscopy, insulin, intraocular pressure, microalbumin, plethysmography, PET brain, and slit-lamp biomicroscopy.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Vitamin B₁₂

SYNONYM/ACRONYM: Cyanocobalamin.

COMMON USE: To assess vitamin B₁₂ levels to assist in diagnosing disorders such as pernicious anemia and malabsorption syndromes.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunochemiluminescent assay)

Age	Conventional Units	SI Units (Conventional Units × 0.738)
Newborn–11 mo	160–1,300 pg/mL	118–959 pmol/L
Adult	200–900 pg/mL	148–664 pmol/L

Values tend to decrease in older adults.

DESCRIPTION: Vitamin B₁₂ has a ringed crystalline structure that surrounds an atom of cobalt. It is essential in DNA synthesis, hematopoiesis, and central nervous system (CNS) integrity. It is derived solely from dietary intake. Animal products are the richest source of vitamin B₁₂. Its absorption depends on the presence of intrinsic factor. Circumstances that may result in a deficiency of this vitamin include the presence of stomach or intestinal disease as well as insufficient dietary intake of foods containing vitamin B₁₂. A significant increase in red blood cells (RBCs) mean corpuscular volume may be an important indicator of vitamin B₁₂ deficiency.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of CNS disorders

- Assist in the diagnosis of megaloblastic anemia
- Evaluate alcoholism
- Evaluate malabsorption syndromes

POTENTIAL DIAGNOSIS

Increased in

Increases are noted in a number of conditions; pathophysiology is unclear.

- Chronic granulocytic leukemia
- Chronic obstructive pulmonary disease
- Chronic renal failure
- Diabetes
- Leukocytosis
- Liver cell damage (hepatitis, cirrhosis) (*stores in damaged hepatocytes are released into circulation; synthesis of transport proteins is diminished by liver damage*)
- Obesity
- Polycythemia vera
- Protein malnutrition (*lack of transport proteins increases circulating levels*)
- Severe congestive heart failure
- Some carcinomas

Decreased in

- Abnormalities of cobalamin transport or metabolism
- Bacterial overgrowth (*vitamin is consumed and utilized by the bacteria*)
- Crohn's disease (*related to poor absorption*)
- Dietary deficiency (*related to insufficient intake, e.g., in vegetarians*)
- *Diphyllobothrium* (fish tapeworm) infestation (*vitamin is consumed and utilized by the parasite*)
- Gastric or small intestine surgery (*related to dietary deficiency or poor absorption*)
- Hypochlorhydria (*related to ineffective digestion resulting in poor absorption*)
- Inflammatory bowel disease (*related to dietary deficiency or poor absorption*)
- Intestinal malabsorption
- Intrinsic factor deficiency (*required for proper vitamin B₁₂ absorption*)
- Late pregnancy (*related to dietary deficiency or poor absorption*)
- Pernicious anemia (*related to dietary deficiency or poor absorption*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase vitamin B₁₂ levels include chloral hydrate.
- Drugs that may decrease vitamin B₁₂ levels include alcohol, amino-salicylic acid, anticonvulsants, ascorbic acid, cholestyramine, cimetidine, colchicine, metformin, neomycin, oral contraceptives, ranitidine, and triamterene.
- Hemolysis or exposure of the specimen to light invalidates results.
- Specimen collection soon after blood transfusion can falsely increase vitamin B₁₂ levels.

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing a vitamin toxicity or deficiency.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal and hematopoietic systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for at least 12 hr before specimen collection. Protocols may vary among facilities.
- ▶ Note that there are no fluid or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions; assure that food has been restricted for at least 12 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Protect the specimen from light.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, as directed by the HCP.
- ▶ **Nutritional Considerations:** Instruct the patient with vitamin B₁₂ deficiency, as appropriate, in the use of vitamin supplements. Inform the patient, as

appropriate, that the best dietary sources of vitamin B₁₂ are meats, fish, poultry, eggs, and milk.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Educate the patient regarding access to nutritional counseling services. Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CBC, CBC RBC count, CBC RBC indices, CBC RBC morphology, CBC WBC count and differential, folate, gastric acid stimulation, gastrin stimulation, homocysteine, and intrinsic factor antibodies.
- ▶ Refer to the Gastrointestinal and Hematopoietic systems tables at the end of the book for related tests by body system.

Vitamin D

SYNONYM/ACRONYM: Cholecalciferol, vitamin D 1,25-dihydroxy.

COMMON USE: To assess vitamin D levels toward diagnosing disorders such as vitamin toxicity, malabsorption, and vitamin deficiency.

SPECIMEN: Serum (1 mL) collected in a red-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: High-performance liquid chromatography)

Form	Conventional Units	SI Units (Conventional Units × 2.496)
Vitamin D 25-dihydroxy	20–100 ng/mL	49.9–249.6 nmol/L
Deficient	Less than 20 ng/mL	Less than 49.9 nmol/L
Insufficient	20–30 ng/mL	49.9–74.9 nmol/L
Optimal	Greater than 30 ng/mL	Greater than 74.9 nmol/L
Possible Toxicity	Greater than 150 ng/mL	Greater than 374.4 nmol/L
	Conventional Units	SI Units (Conventional Units × 2.6)
Vitamin D 1,25-dihydroxy	15–60 pg/mL	39–156 pmol/L

DESCRIPTION: Vitamin D is a group of interrelated sterols that have hormonal activity in multiple organs and tissues of the body, including the kidneys, liver, skin, and bones. There are two metabolically active forms of vitamin D: vitamin D 25-dihydroxy and vitamin D 1,25-dihydroxy. Ergocalciferol (vitamin D₂) is formed when ergosterol in plants is exposed to sunlight. Ergocalciferol is absorbed by the stomach and intestine when orally ingested. Cholecalciferol (vitamin D₃) is formed when the skin is exposed to sunlight or ultraviolet light. Vitamins D₂ and D₃ enter the bloodstream after absorption. Vitamin D₃ is converted to vitamin D 25-dihydroxy by the liver and is the major circulating form of the vitamin. Vitamin D₂ is converted to vitamin D 1,25-dihydroxy (calcitriol) by the kidneys and is the more biologically active form. Vitamin D acts with parathyroid hormone and calcitonin to regulate calcium metabolism and osteoblast function. The effects of vitamin D deficiency have been studied for many years, and continued research indicates a link between vitamin D deficiency and the development of

diseases such as heart failure, stroke, hypertension, cancer, autism, multiple sclerosis, type 2 diabetes, systemic lupus erythematosus, depression, and immune function. The amount of vitamin D₃ produced by exposure of the skin to UV radiation depends on the intensity of the radiation as well as the duration of exposure. The use of lotions containing sun block significantly decreases production of vitamin D₃.

This procedure is contraindicated for: N/A

INDICATIONS

- Differential diagnosis of disorders of calcium and phosphorus metabolism
- Evaluate deficiency or suspected toxicity
- Investigate bone diseases
- Investigate malabsorption

POTENTIAL DIAGNOSIS

Increased in

- Endogenous vitamin D intoxication (*in conditions such as sarcoidosis, cat scratch disease, and some lymphomas, extrarenal conversion of 25-dihydroxy to*

1,25-dihydroxy vitamin D occurs with a corresponding abnormal elevation of calcium)

- Exogenous vitamin D intoxication

Decreased in

- Bowel resection (*related to lack of absorption*)
- Celiac disease (*related to lack of absorption*)
- Inflammatory bowel disease (*related to lack of absorption*)
- Malabsorption (*related to lack of absorption*)
- Osteomalacia (*related to dietary insufficiency*)
- Pancreatic insufficiency (*lack of digestive enzymes to metabolize fat-soluble vitamin D; malabsorption*)
- Rickets (*related to dietary insufficiency*)
- Thyrotoxicosis (*possibly related to increased calcium loss through sweat, urine, or feces with corresponding decrease in vitamin D levels*)

CRITICAL FINDINGS

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the

critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. Most cases of toxicity are brought about by oversupplementing and can be avoided by consulting a qualified nutritionist for recommended daily dietary and supplemental allowances. Signs and symptoms of vitamin D toxicity include nausea, loss of appetite, vomiting, polyuria, muscle weakness, and constipation.

INTERFERING FACTORS

- Drugs that may increase vitamin D levels include pravastatin.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Health maintenance (<i>Related to failure to regulate diet and dietary supplements;</i>	Inability or failure to recognize or process information toward improving health and preventing illness with	Assess health habits to obtain an interventional baseline; obtain a current health history; identify the patient's and family's

(table continues on page 1600)

Problem	Signs & Symptoms	Interventions
<i>inadequate exposure to sunlight to support optimal vitamin D intake; inability to obtain or understand health-related information)</i>	associated mental and physical effects	learning style; refrain from using medical jargon; observe for altered literacy cues; provide most important information first and reinforce with additional education; ensure the patient understands the ramifications of a lack of vitamin D on the health of the patient's bones
Nutrition (<i>Related to lack of vitamin D-rich foods in the diet</i>)	Failure to select vitamin D-rich foods such as fish, fortified milk, breads, cereals, orange juice, eggs and mushrooms; difficulty in opening food containers and feeding self	Determine the patient's ability to select vitamin D-rich foods; discuss the efficacy of increasing exposure to sunlight; collaborate with the physician in determining the need for vitamin D supplements
Body image (<i>Related to deformities associated with bone loss from osteoporosis and vitamin D insufficiency</i>)	Visible physical deformity; presence of kyphosis or lordosis; verbalized negative feelings about appearance; altered social interactions with others due to embarrassment about appearance	Acknowledge the patient's emotional distress; encourage a positive attitude; coordinate meetings with a support group within the community
Self-care (<i>Related to loss of bone mass and physical deformity; pain; and limited range of motion</i>)	Difficulty fastening clothing; difficulty performing personal hygiene; unable to maintain appropriate appearance; difficulty with independent mobility	Reinforce self-care techniques as taught by occupational therapy; ensure the patient has adequate time to perform self-care; encourage use of assistive devices to maintain independence

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing vitamin toxicity or deficiency.
- ▶ Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's gastrointestinal and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional

supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- Nutritional Considerations:** Educate the patient with vitamin D deficiency, as appropriate, that the main dietary sources of vitamin D are fortified dairy foods and cod liver oil. Explain to the patient that vitamin D is also synthesized by the body, in the skin, and is activated by sunlight.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- Recognize anxiety related to test results and answer any questions or address any concerns voiced by the patient or family.
- Educate the patient regarding access to nutritional counseling services.
- Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
- Use plain, culturally appropriate and age-appropriate language in providing education to the patient and family.
- Provide written material that is appropriate to the patient's language and literacy level.

Expected Patient Outcomes:

Knowledge

- Discusses the importance of altering the diet to contain vitamin D-rich foods
- Concludes that adherence to a recommended vitamin D intake can preserve bone integrity

Skills

- Designs a strategy to ensure the daily minimal sun exposure for vitamin D
- Demonstrates proficiency in taking vitamin D supplements as recommended

Attitude

- Follows the recommendation to take positive measures to improve health
- Responds to the need to protect independent function related to lost bone mass by adhering to recommended vitamin D intake

RELATED MONOGRAPHS:

- Related tests include amylase, ANCA, biopsy intestinal, calcium, capsule endoscopy, colonoscopy, fecal analysis, fecal fat, antibodies gliadin

antibodies, kidney stone panel, laparoscopy abdominal, lipase, osteocalcin, oxalate, phosphorus, and proctosigmoidoscopy.

Refer to the Gastrointestinal and Musculoskeletal systems tables at the end of the book for related tests by body system.

Vitamin E

SYNONYM/ACRONYM: Tocopherol.

COMMON USE: To assess vitamin E levels to assist in diagnosing vitamin toxicity, malabsorption, neuromuscular disorders, and vitamin deficiency.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: High-performance liquid chromatography)

Age	Conventional Units	SI Units (Conventional Units × 2.322)
Newborn	1–3.5 mg/L	2.3–8.1 micromol/L
Neonate	2.5–3.7	5.8–8.6 micromol/L
2–5 mo	2–6	4.6–13.9 micromol/L
6–12 mo	3.5–8	8.1–18.6 micromol/L
1–6 yr	3–9	7–20.9 micromol/L
7–12 yr	4–9 mg/L	9.3–20.9 micromol/L
13–19 yr	6–10 mg/L	13.9–23.2 micromol/L
Adult	5–18 mg/L	11.6–41.8 micromol/L

Values tend to decrease in older adults.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Obstructive liver disease (*related to malabsorption associated with obstructive liver disease*)
- Vitamin E intoxication (*related to excessive intake*)

Decreased in

- Abetalipoproteinemia (*rare inherited disorder of fat metabolism evidenced by poor absorption of fat and fat-soluble vitamin E*)

- Hemolytic anemia (*related to deficiency of vitamin E, an important antioxidant that protects RBC cell membranes from weakening*)
- Malabsorption disorders, such as biliary atresia, cirrhosis, cystic fibrosis, chronic pancreatitis, pancreatic carcinoma, and chronic cholestasis

CRITICAL FINDINGS

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a

notification form with review by Risk Management.

Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. Most cases of toxicity are brought about by oversupplementing and can be avoided by consulting a qualified nutritionist for recommended daily dietary and supplemental allowances. *Note:* Excessive supplementation of vitamin E (greater than 60 times the recommended dietary allowance over a period of 1 yr or longer) can result in excessive bleeding, delayed healing of wounds, and depression.

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Vitamin K

SYNONYM/ACRONYM: Phylloquinone, phytonadione.

COMMON USE: Assessment of vitamin K levels to assist in diagnosing bleeding disorders where etiology is unknown, identify vitamin toxicity, and evaluate symptoms related to chronic antibiotic use.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: High-performance liquid chromatography)

Conventional Units

0.13–1.19 ng/mL

SI Units (Conventional Units × 2.22)

0.29–2.64 nmol/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Excessive administration of vitamin K

Decreased in

- Antibiotic therapy (*related to decreased intestinal flora*)
- Chronic fat malabsorption (*related to lack of digestive enzymes and poor absorption*)
- Cystic fibrosis (*related to lack of digestive enzymes and poor absorption*)
- Diarrhea (in infants) (*related to increased loss in feces*)
- Gastrointestinal disease (*related to malabsorption*)
- Hemorrhagic disease of the newborn (*newborns normally have low levels of vitamin K; neonates at risk are those who are not given a prophylactic vitamin K shot at birth or those receiving nutrition strictly from breast milk, which has less vitamin K than cow's milk*)
- Hypoprothrombinemia (*related to insufficient levels of prothrombin, a vitamin K–dependent protein*)
- Liver disease (*interferes with storage of vitamin K*)
- Obstructive jaundice (*related to insufficient levels of bile salts required for absorption of vitamin K*)
- Pancreatic disease (*related to insufficient levels of enzymes to metabolize vitamin K*)

CRITICAL FINDINGS

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. The naturally occurring forms, vitamins K₁ and K₂, do not cause toxicity. Signs and symptoms of vitamin K₃ toxicity include bleeding and jaundice. Possible interventions include withholding the source.

Vitamins A, B₁, B₆, and C

SYNONYM/ACRONYM: Vitamin A: retinol, carotene; vitamin B₁: thiamine; vitamin B₆: pyridoxine, P-5'-P, pyridoxyl-5-phosphate; vitamin C: ascorbic acid.

COMMON USE: To assess vitamin deficiency or toxicity to assist in diagnosing nutritional disorders such as malabsorption; disorders that affect vision, skin, and bones; and other diseases.

SPECIMEN: Serum (1 mL) collected in a red-top tube each for vitamins A and C; plasma (1 mL) collected in a lavender-top (EDTA) tube each for vitamins B₁ and B₆.

NORMAL FINDINGS: (Method: High-performance liquid chromatography)

Vitamin	Age	Conventional Units	SI Units
Vitamin A	Birth–1 yr	14–52 mcg/dL	(<i>Conventional Units</i> × 0.0349) 0.49–1.81 micromol/L
	1–6 yr	20–43 mcg/dL	0.7–1.5 micromol/L
	7–12 yr	26–49 mcg/dL	0.91–1.71 micromol/L
	13–19 yr	26–72 mcg/dL	0.91–2.51 micromol/L
	Adult	30–120 mcg/dL	1.05–4.19 micromol/L
Vitamin B ₁		0.21–0.43 mcg/dL	(<i>Conventional Units</i> × 29.6) 6.2–12.7 micromol/L
			(<i>Conversion Factor</i> × 4.046) 20–121 nmol/L
Vitamin B ₆		5–30 ng/mL	(<i>Conventional Units</i> × 56.78) 34.1–107.9 micromol/L
Vitamin C		0.6–1.9 mg/dL	

Vitamin B₁, vitamin B₆, and vitamin C levels tend to decrease in older adults.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Vitamin A:
 - Chronic kidney disease
 - Idiopathic hypercalcemia in infants
 - Vitamin A toxicity

Decreased in

- Vitamin A:
 - Abetalipoproteinemia (*related to poor absorption*)

Carcinoid syndrome (*related to poor absorption*)

Chronic infections (*vitamin A deficiency decreases ability to fight infection*)

Cystic fibrosis (*related to poor absorption*)

Disseminated tuberculosis (*related to poor absorption*)

Hypothyroidism (*condition decreases ability of beta carotene to convert to vitamin A*)

Infantile blindness (*related to dietary deficiency*)

Liver, gastrointestinal (GI), or pancreatic disease (*related to malabsorption or poor absorption*)

Night blindness (*related to chronic dietary deficiency or lack of absorption*)

Protein malnutrition (*related to dietary deficiency*)

Sterility and teratogenesis (*related to dietary deficiency*)

Zinc deficiency (*zinc is required for generation of vitamin A transport proteins*)

• **Vitamin B₁:**

Alcoholism (*related to dietary deficiency*)

Carcinoid syndrome (*related to dietary deficiency or lack of absorption*)

Hartnup's disease (*related to dietary deficiency*)

Pellagra (*related to dietary deficiency*)

• **Vitamin B₆ (*this vitamin is involved in many essential functions, such as nucleic acid synthesis, enzyme activation, antibody production, electrolyte balance, and RBC formation; deficiencies result in a variety of conditions*):**

Alcoholism (*related to dietary deficiency*)

Asthma

Carpal tunnel syndrome

Gestational diabetes

Lactation (*related to dietary deficiency and/or increased demand*)

Malabsorption

Malnutrition

Neonatal seizures

Normal pregnancies (*related to dietary deficiency and/or increased demand*)

Occupational exposure to hydrazine compounds (*enzymatic pathways are altered by hydralazines in a manner that increases excretion of vitamin B₆*)

Pellagra (*related to dietary deficiency*)

Pre-eclamptic edema

Renal dialysis

Uremia

• **Vitamin C:**

Alcoholism (*related to dietary deficiency*)

Anemia (*related to dietary deficiency*)

Cancer (*related to dietary deficiency or lack of absorption*)

Hemodialysis (*vitamin C is lost during the treatment*)

Hyperthyroidism (*related to dietary deficiency and/or increased demand*)

Malabsorption

Pregnancy (*related to dietary deficiency and/or increased demand*)

Rheumatoid disease

Scurvy (*related to dietary deficiency or lack of absorption*)

CRITICAL FINDINGS 

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for

toxicity is especially important to consider with respect to fat-soluble vitamins (A, D, E, and K), which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body. Most cases of toxicity are brought about by oversup-

plementing and can be avoided by consulting a qualified nutritionist for recommended daily dietary and supplemental allowances. Signs and symptoms of vitamin A toxicity may include headache, blurred vision, bone pain, joint pain, dry skin, and loss of appetite.

White Blood Cell Scan

SYNONYM/ACRONYM: Infection scintigraphy, inflammatory scan, labeled autologous leukocytes, labeled leukocyte scan, WBC imaging.

COMMON USE: To assist in identification of abscess, infection, and inflammation of the bone, bowel, wound, and skin.

AREA OF APPLICATION: Whole body.

CONTRAST: IV radionuclide combined with white blood cells.

DESCRIPTION: Because white blood cells (WBCs) naturally accumulate in areas of inflammation, the WBC scan uses radiolabeled WBCs to help determine the site of an acute infection or confirm the presence or absence of infection or inflammation at a suspected site. A gamma camera detects the radiation emitted from the injected radionuclide, and a representative image of the radionuclide distribution is obtained and recorded or stored electronically. Because of its better image resolution and greater specificity for acute infections, the WBC scan has replaced scanning with gallium-67 citrate (Ga-67). Some chronic infections associated with pulmonary disease, however, may be better imaged with Ga-67. The WBC scan is especially helpful in detecting postoperative infection sites and in documenting lack of residual infection after a course of therapy.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of infectious or inflammatory diseases
- Differentiate infectious from noninfectious process
- Evaluate the effects of treatment
- Evaluate inflammatory bowel disease (IBD)
- Evaluate patients with fever of unknown origin
- Evaluate postsurgical sites and wound infections
- Evaluate suspected infection of an orthopedic prosthesis
- Evaluate suspected osteomyelitis

POTENTIAL DIAGNOSIS

Normal findings in

- No focal localization of the radionuclide, along with some slight localization of the radionuclide within the reticuloendothelial system (liver, spleen, and bone marrow)

Abnormal findings in

- Abscess
- Arthritis
- Infection
- Inflammation
- IBD
- Osteomyelitis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Retained barium from a previous radiological procedure, which may inhibit visualization of an abdominal lesion.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Other nuclear scans done within 48 hr and Ga-67 scans within 4 wk before the procedure.
- Lesions smaller than 1 to 2 cm, which may not be detectable.
- A distended bladder, which may obscure pelvic detail.

Other considerations

- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- Patients with a low WBC count may need donor WBCs to complete the radionuclide labeling process; otherwise, Ga-67 scanning should be performed instead.
- False-negative images may be a result of hemodialysis, hyperglycemia, hyperalimentation, steroid therapy, and antibiotic therapy.
- The presence of multiple myeloma or thyroid cancer can result in a false-negative scan for bone abnormalities.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on

the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for the presence of infection or inflammation.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including barium examinations.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side

effects. Inform the patient that the procedure is performed in a nuclear medicine department by an HCP. It usually takes approximately 1 to 6 hr, and delayed images are needed 24 hr later. The patient may leave the department and return later to undergo delayed imaging.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no dietary or medication restrictions prior to the procedure, unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injecting radionuclides are invasive procedures. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; hematoma **related to blood leakage into the tissue following needle insertion**; infection **that might occur if bacteria from the skin surface is introduced at the puncture site**; or nerve injury **that might occur if the needle strikes a nerve.**

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

- ▶ Ensure the patient has removed all external metallic objects prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs, and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Administer sedative to a child or to an uncooperative adult, as ordered.
- ▶ Draw a 50- to 80-mL sample of blood on the day of the test for separating the WBCs from the blood and an in vitro process of labeling with radionuclide.
- ▶ IV radionuclide-labeled autologous WBCs are administered.
- ▶ Images are recorded 1 to 6 hr post-injection depending on the radionuclide used. Delayed images may be required at 24 hr after the injection.
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ If abdominal abscess or infection is suspected, laxatives or enemas may be ordered before delayed imaging.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient

that radionuclide is eliminated from the body within 6 to 24 hr.

- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test

results on the patient's lifestyle.

Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography pulmonary, bone scan, colonoscopy, CBC, CBC WBC count and differential, CT abdomen, CT pelvis, CT spine, culture (blood, skin, wound), ESR, fecal analysis, gallium scan, GI blood loss scan, KUB, MRI musculoskeletal, MRI pelvis, MRI spine, proctosigmoidoscopy, radiography bone, US abdomen, US pelvis, and vitamin D.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Zinc

SYNONYM/ACRONYM: Zn.

COMMON USE: To assist in assessing for vitamin deficiency or toxicity, monitor therapeutic interventions, and assist in diagnosing disorders such as acrodermatitis enteropathica.

SPECIMEN: Serum (1 mL) collected in a trace element-free, royal blue-top tube.

NORMAL FINDINGS: (Method: Atomic absorption spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.153)
Newborn–6 mo	26–141 mcg/dL	4–21.6 micromol/L
6–11 mo	29–131 mcg/dL	4.4–20 micromol/L
1–4 yr	31–115 mcg/dL	4.7–17.6 micromol/L
4–5 yr	48–119 mcg/dL	7.3–18.2 micromol/L
6–9 yr	48–129 mcg/dL	7.3–19.7 micromol/L
10–13 yr	25–148 mcg/dL	3.8–22.6 micromol/L
14–17 yr	46–130 mcg/dL	7–19.9 micromol/L
Adult	70–120 mcg/dL	10.7–18.4 micromol/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Zinc is contained in and secreted by numerous types of cells in the body. Damaged cells release zinc into circulation and increase blood levels.

- Anemia (related to competitive relationship with copper; copper deficiency is associated with decreased production of red blood cells)

Decreased in

This trace metal is an essential component of enzymes that participate in protein and carbohydrate metabolism. It is involved in DNA replication, insulin storage, carbon dioxide gas exchange, cellular immunity and healing, promotion of body growth, and sexual maturity. Deficiencies result in a variety of conditions.

- Acrodermatitis enteropathica (*congenital abnormality that affects zinc uptake and results in zinc deficiency*)
- AIDS
- Acute infections
- Acute stress
- Burns
- Cirrhosis
- Conditions that decrease albumin (*related to lack of available transport proteins*)
- Diabetes
- Long-term total parenteral nutrition
- Malabsorption
- Myocardial infarction
- Nephrotic syndrome
- Nutritional deficiency
- Pregnancy (*related to increased uptake by fetus; related to excessive levels of iron and folic acid prescribed during pregnancy and which interfere with absorption*)
- Pulmonary tuberculosis

CRITICAL FINDINGS: N/A

Endocrine System

Laboratory Tests Associated With the Endocrine System

Adrenocorticotrophic hormone (and challenge tests), 10–19	C-peptide, 617–620
Aldosterone, 28–34	Dehydroepiandrosterone sulfate, 711–713
Angiotensin-converting enzyme, 109–110	Dexamethasone suppression test, 609
Anion gap, 110	Estradiol, 768
Antibodies, antithyroglobulin and antithyroid peroxidase, 132–133	Follicle-stimulating hormone, 816–821
Antidiuretic hormone, 153–154	Fructosamine, 821–822
Biopsy, thyroid, 272–276	Glucagon, 852–853
Monograph contains information regarding genetic studies.	Glucose (fasting, random, 2-hr postprandial), 853–860
Calcitonin and calcitonin stimulation tests, 339–340	Monograph contains information regarding genetic studies.
Calcium, urine, 352–353	Glucose tolerance tests, 865–874
Catecholamines, blood and urine, 373–378	Glycated hemoglobin, 874–880
Chloride, blood, 400–404	Growth hormone, stimulation and suppression tests, 890–891
Chloride, sweat, 405–409	Homovanillic acid, 931–933
Monograph contains information regarding genetic studies.	Human chorionic gonadotropin, 934–938
Cortisol and challenge tests, 608–617	5-Hydroxyindoleacetic acid, 946
	Insulin and insulin response to glucose, 977–981
	Insulin antibodies, 981–984
	Ketones, blood and urine, 1004–1008

Laboratory Tests Associated With the Endocrine System

Lactic acid, 1013–1018	Prolactin, 1302–1305
Luteinizing hormone, 1057–1061	Renin, 1355–1358
Magnesium, blood, 1071–1076	Sodium, blood, 1396–1402
Magnesium, urine, 1076–1077	Sodium, urine, 1402–1405
Metanephrines, 1137–1139	Testosterone, total, 1421–1425
Metyrapone stimulation, 609–610	Thyroglobulin, 1425–1426
Microalbumin, 1141–1147	Thyroid-binding inhibitory immunoglobulin, 1426–1427
Newborn screening, 1164–1194	Thyroid-stimulating hormone, 1431–1436
Monograph contains information regarding genetic studies.	Thyroid-stimulating immunoglobulins, 1436
Osmolality, blood and urine, 1195–1199	Thyroxine-binding globulin, 1437
Parathyroid hormone, 1217–1221	Thyroxine, free, 1438–1442
Phosphorus, blood, 1240–1243	Thyroxine, total, 1442–1445
Phosphorus, urine, 1244	Triiodothyronine, free, 1459–1461
Potassium, blood, 1277–1285	Triiodothyronine, total, 1461–1463
Potassium, urine, 1286–1289	Urinalysis, 1560–1570
Prealbumin, 1290–1292	Vanillylmandelic acid, urine, 1576–1578
Progesterone, 1299–1302	

Diagnostic Tests Associated With the Endocrine System

Adrenal gland scan, 6–10	Parathyroid scan, 1221–1224
Angiography, adrenal, 80–85	Radioactive iodine uptake, 1339–1342
Computed tomography, pituitary, 574–578	Sialography, 1387–1390
Lymphangiography, 1065–1070	Thyroid scan, 1427–1430
Magnetic resonance imaging, pancreas, 1107–1111	Ultrasound, thyroid and parathyroid, 1527–1530
Magnetic resonance imaging, pituitary, 1116–1120	

Gastrointestinal System

Laboratory Tests Associated With the Gastrointestinal System

Albumin and albumin/globulin ratio, 24–27	Bioterrorism and public health safety concerns: testing for toxins and infectious agents, 276–288
Amylase, 63–69	Calcium, blood, 340–347
Antibodies, antineutrophilic cytoplasmic, 122	Calcium, ionized, 348–351
Antibodies, gliadin (immunoglobulin G and immunoglobulin A), endomysial (immunoglobulin A), tissue transglutaminase (immunoglobulin A), 137–140 Monograph contains information regarding genetic studies.	Cancer antigens, 358–362
Biopsy, intestinal, 240–242	Monograph contains information regarding genetic studies.
	Cholesterol, total, 428–434
	Complete blood count, 470–479
	Complete blood count, hematocrit, 479–485
	Complete blood count, hemoglobin, 486–494

(table continues on page 1616)

Laboratory Tests Associated With the Gastrointestinal System

Complete blood count, RBC count, 503–509	<i>Helicobacter pylori</i> antibody, 895–898
Complete blood count, RBC indices, 510–514	5-Hydroxyindoleacetic acid, 946
Complete blood count, RBC morphology and inclusions, 514–520	Intrinsic factor antibodies, 994
Culture, bacterial, stool, 667–670	Iron, 994–1000
Culture, viral, 680–683	Lactose tolerance test, 1018–1022
D-Xylose tolerance test, 718–719	Lipase, 1035–1038
Endomysial antibodies (immunoglobulin G and immunoglobulin A), 119–122	Magnesium, blood, 1071–1076
Fecal analysis, 778–783	Magnesium, urine, 1076–1077
Monograph contains information regarding genetic studies.	Ova and parasites, stool, 1203–1207
Fecal fat, 783–784	Oxalate, urine, 1207–1208
Folate, 812–816	Peritoneal fluid analysis, 1235–1239
Fructosamine, 821–822	Phosphorus, blood, 1240–1243
Gastric analysis and gastric acid stimulation test, 834–835	Potassium, blood, 1277–1285
Gastrin and gastrin stimulation test, 839–840	Potassium, urine, 1286–1289
Genetic testing, 848–852	Prealbumin, 1290–1292
Monograph contains information regarding genetic studies.	Protein, blood, total and fractions, 1310–1313
Gram stain, 884–886	Transglutaminase antibodies (immunoglobulin G and immunoglobulin A), 133–137
	Triglycerides, 1452–1459
	Vitamin B ₁₂ , 1595–1597
	Vitamin D, 1597–1602
	Vitamin E, 1602–1603
	Vitamins A, B ₁ , B ₆ , and C, 1605–1607

Diagnostic Tests Associated With the Gastrointestinal System

Barium enema, 197–202	Gastric emptying scan, 836–843
Barium swallow, 202–206	Gastroesophageal reflux scan, 840–843
Capsule endoscopy, 362–366	Gastrointestinal blood loss scan, 844–848
Cholangiography, percutaneous transhepatic, 409–414	Hydrogen breath test, 1018–1022
Cholangiography, postoperative, 414–418	Kidney, ureter, and bladder study, 1008–1011
Cholangiopancreatography, endoscopic retrograde, 418–422	Laparoscopy, abdomen, 1023–1026
Colonoscopy, 456–461	Magnetic resonance imaging, abdomen, 1082–1087
Computed tomography, abdomen, 532–537	Meckel's diverticulum scan, 1129–1133
Computed tomography, colonoscopy, 559–564	Positron emission tomography, pelvis, 1273–1277
Computed tomography, pancreas, 564–569	Proctosigmoidoscopy, 1295–1299
Computed tomography, pelvis, 569–574	Ultrasound, abdomen, 1478–1480
Esophageal manometry, 760–763	Ultrasound, pancreas, 1512–1514
Esophagogastroduodenoscopy, 763–767	Upper gastrointestinal and small bowel series, 1535–1540
	Urea breath test, 1540–1542

Genitourinary System

Laboratory Tests Associated With the Genitourinary System

Acetaminophen, 69–74	Complete blood count, hemoglobin, 486–494
Acid phosphatase, prostatic, 5–6	Complete blood count, RBC count, 503–509
Albumin and albumin/globulin ratio, 24–27	Creatinine, blood, 631–638
Aldosterone, 28–34	Creatinine, urine, and creatinine clearance, urine, 638–643
Amikacin, 154–161	Culture, bacterial, urine, 673–676
Amino acid screen, blood, 47–48	Culture, viral, 680–683
Monograph contains information regarding genetic studies.	Cyclosporine, 968–974
Amino acid screen, urine, 48	Cytology, urine, 700–702
Monograph contains information regarding genetic studies.	Erythropoietin, 757–759
Anion gap, 110	Genetic testing, 848–852
Antiarrhythmic drugs, 111–117	Monograph contains information regarding genetic studies.
Antimicrobial drugs, 154–161	Gentamicin, 154–161
Antibodies, anti-glomerular basement membrane, 120	Gram stain, 884–886
Antibodies, antineutrophil cytoplasmic, 122	Lithium, 161–166
Anticonvulsant drugs, 140–147	Monograph contains information regarding genetic studies.
Monograph contains information regarding genetic studies.	Magnesium, blood, 1071–1076
Antidepressant drugs, 148–152	Magnesium, urine, 1076–1077
Monograph contains information regarding genetic studies.	Methotrexate, 968–974
Antidiuretic hormone, 153–154	Microalbumin, 1141–1147
Antipsychotic drugs, 161–166	Newborn screening, 1164–1194
Monograph contains information regarding genetic studies.	Monograph contains information regarding genetic studies.
β_2 -Microglobulin, blood and urine, 191–197	Osmolality, blood and urine, 1195–1199
Biopsy, bladder, 214–218	Oxalate, urine, 1207–1208
Biopsy, kidney, 243–246	Phosphorus, blood, 1240–1243
Biopsy, prostate, 263–268	Phosphorus, urine, 1244
Bioterrorism and public health safety concerns: testing for toxins and infectious agents, 276–288	Potassium, blood, 1277–1285
Bladder cancer markers, urine, 289–291	Potassium, urine, 1286–1289
Monograph contains information regarding genetic studies.	Prostate-specific antigen, 1305–1310
Blood gases, 293–307	Protein, urine: total quantitative and fractions, 1315–1318
Calcium, blood, 340–347	Renin, 1355–1358
Calcium, ionized, 348–351	Salicylate, 69–74
Calcium, urine, 352–353	Sodium, blood, 1396–1402
Calculus, kidney stone panel, 353–358	Sodium, urine, 1402–1405
Carbon dioxide, 366–369	Tobramycin, 154–161
Chloride, blood, 400–404	Urea nitrogen, blood, 1542–1548
Complete blood count, 470–479	Urea nitrogen, urine, 1549
Complete blood count, hematocrit, 479–485	Uric acid, blood, 1553–1559
	Uric acid, urine, 1559
	Urinalysis, 1560–1570
	Vancomycin, 154–161
	Vitamins A, B ₁ , B ₆ , and C, 1605–1607

Diagnostic Tests Associated With the Genitourinary System

Angiography, renal, 104–108	Computed tomography, pelvis, 569–574
Bladder scan, 1497–1500	Computed tomography, renal, 579–583

Diagnostic Tests Associated With the Genitourinary System

Cystometry, 683–687	Magnetic resonance imaging, pelvis, 1112–1116
Cystoscopy, 687–690	Renogram, 1359–1362
Cystourethrography, voiding, 691–694	Retrograde ureteropyelography, 1366–1370
Digital rectal examination (DRE), 1518–1521	Ultrasound, abdomen, 1478–1480
Electromyography, pelvic floor sphincter, 743–745	Ultrasound, bladder, 1497–1500
IV pyelography, 990–993	Ultrasound, kidney, 1503–1506
Kidney, ureter, and bladder study, 1008–1011	Ultrasound, prostate, 1518–1521
Magnetic resonance imaging, abdomen, 1082–1087	Urethrography, retrograde, 1549–1552

Hematopoietic System

Laboratory Tests Associated With the Hematopoietic System

11-Dehydrothromboxane B ₂ , 1139–1140	Complete blood count, RBC indices, 510–514
δ-Aminolevulinic acid, 49	Complete blood count, RBC morphology and inclusions, 514–520
Anion gap, 110	Complete blood count, WBC count and differential, 520–532
Antibodies, cardiolipin, immunoglobulin A, immunoglobulin G, and immunoglobulin M, 133–137	Coombs' antiglobulin, direct, 599–603
Antithrombin III, 166–167	Coombs' antiglobulin, indirect, 603–606
β-2 Glycoprotein 134	Copper, 606–607
Biopsy, bone marrow, 222–227	CYP2C19, 497–498
Bioterrorism and public health safety concerns: testing for toxins and infectious agents, 276–288	D-Dimer, 707–711
Bleeding time, 291–292	Eosinophil count, 750
Blood groups and antibodies, 308–315	Erythrocyte protoporphyrin, free, 751
Calcium, blood, 340–347	Erythrocyte sedimentation rate, 751–757
Calcium, ionized, 348–351	Erythropoietin, 757–759
CD4/CD8 enumeration, 379–384	Ferritin, 784–787
Clot retraction, 440–441	Fibrinogen degradation products, 802–807
Coagulation factors, 441–450	Fibrinogen, 799–802
Monograph contains information regarding genetic studies.	Folate, 812–816
Complete blood count, 470–479	Genetic testing, 848–852
Complete blood count, hematocrit, 479–484	Monograph contains information regarding genetic studies.
Complete blood count, hemoglobin, 485–494	Glucose-6-phosphate dehydrogenase, 864
Complete blood count, platelet count, 495–503 Monograph contains information regarding genetic studies.	Ham's test for paroxysmal nocturnal hemoglobinuria, 892
Complete blood count, RBC count, 503–509	Haptoglobin, 892–894
	Hemoglobin electrophoresis, 898–903
	Hemosiderin, 904
	Homocysteine and methylmalonic acid, 927–931

Laboratory Tests Associated With the Hematopoietic System

Immunofixation electrophoresis, blood and urine, 954–958	Osmotic fragility, 1199
Immunoglobulins A, D, G, and M, 962–967	Partial thromboplastin time, activated, 1225–1229
International normalized ratio (INR), 1319–1326	Plasminogen, 1244–1245
Intrinsic factor antibodies, 994	Platelet antibodies, 1245–1246
Iron, 994–1000	Porphyryns, urine, 1256–1257
Iron-binding capacity (total), transferrin, and iron saturation, 1000–1003	Protein C, 1314
Kleihauer-Betke test, 1011	Protein S, 1314–1315
Lactate dehydrogenase and isoenzymes, 1012–1013	Prothrombin time and INR, 1319–1326
Lead, 1031–1033	Monograph contains information regarding genetic studies.
Leukocyte alkaline phosphatase, 1034 Monograph contains information regarding genetic studies.	Pyruvate kinase, 1337–1338
Lupus anticoagulant antibodies, 1053–1057	Red blood cell cholinesterase, 1350
Methemoglobin, 1139–1140	Reticulocyte count, 1363–1365
	Sickle cell screen, 1391–1393
	Transferrin, 1450–1452
	Urinalysis, 1560–1570
	Vitamin B ₁₂ , 1595–1597
	Vitamin E, 1602–1603
	Vitamin K, 1603–1604

Diagnostic Tests Associated With the Hematopoietic System

Computed tomography, spleen, 589–593	Lymphangiography, 1065–1070
Liver and spleen scan, 1040–1044	Ultrasound, spleen, 1524–1527

Hepatobiliary System

Laboratory Tests Associated With the Hepatobiliary System

Acetaminophen, 69–74	α_1 -Antitrypsin and α_1 -antitrypsin phenotyping, 167–168
Acetylsalicylic acid, 69–74	Monograph contains information regarding genetic studies.
Alanine aminotransferase, 19–23	Aspartate aminotransferase, 180–185
Albumin, 24–27	Bilirubin and bilirubin fractions, 206–214
Aldolase, 27–28	Biopsy, liver, 247–250
Alkaline phosphatase and isoenzymes, 34–38	Bioterrorism and public health safety concerns: testing for toxins and infectious agents, 276–288
Amino acid, blood, 47–48 Monograph contains information regarding genetic studies.	Calcium, blood, 340–347
Amino acid, urine, 48 Monograph contains information regarding genetic studies.	Calcium, ionized, 348–351
Amitriptyline, 148–152 Monograph contains information regarding genetic studies.	Carbamazepine, 140–147
Ammonia, 50–54	Monograph contains information regarding genetic studies.
Amylase, 63–69	Ceruloplasmin, 391
Antibodies, actin (smooth muscle), and mitochondrial M2, 121	Cholesterol, total, 428–434
Antibodies, antineutrophilic cytoplasmic, 122	Coagulation factors, 441–450
	Monograph contains information regarding genetic studies.
	Complete blood count, 470–479

(table continues on page 1620)

Laboratory Tests Associated With the Hepatobiliary System

- Complete blood count, hematocrit, 479–485
- Complete blood count, hemoglobin, 486–494
- Complete blood count, RBC count, 503–509
- Complete blood count, RBC morphology and inclusions, 514–520
- Copper, 606–607
- Diazepam, 148–152 **Monograph contains information regarding genetic studies.**
- Doxepin, 148–152 **Monograph contains information regarding genetic studies.**
- Ethosuximide, 147–154 **Monograph contains information regarding genetic studies.**
- Fibrinogen, 799–802
- δ -Glutamyltransferase, 829–834
- Genetic testing, 848–852 **Monograph contains information regarding genetic studies.**
- Haloperidol, 161–166 **Monograph contains information regarding genetic studies.**
- Haptoglobin, 892–894
- Hepatitis A antibody, 904–908
- Hepatitis B antigen and antibody, 908–913
- Hepatitis C antibody, 914–918
- Hepatitis D antibody, 918–919
- Hepatitis E antibody, 919
- Imipramine, 148–152 **Monograph contains information regarding genetic studies.**
- Infectious mononucleosis screen, 974–977
- International normalized ratio (INR), 1318–1326
- Lactate dehydrogenase and isoenzymes, 1012–1013
- Lactic acid, 1013–1018
- Lipase, 1035–1038
- Lipoprotein(a), 428–434
- Newborn screening, 1164–1194
- Monograph contains information regarding genetic studies.**
- Nortriptyline, 148–152 **Monograph contains information regarding genetic studies.**
- Partial thromboplastin time, activated, 1225–1230
- Phenobarbital, 140–147 **Monograph contains information regarding genetic studies.**
- Phenytoin, 140–147 **Monograph contains information regarding genetic studies.**
- Prealbumin, 1290–1292
- Primidone, 140–147 **Monograph contains information regarding genetic studies.**
- Protein, blood, total and fractions, 1310–1313
- Protein C, 1314
- Protein S, 1314–1315
- Prothrombin time and INR, 1319–1326
- Monograph contains information regarding genetic studies.**
- Pseudocholinesterase, 1327–1328
- Urea nitrogen, blood, 1542–1548
- Uric acid, blood, 1553–1559
- Urinalysis, 1560–1570
- Valproic acid, 140–147
- Monograph contains information regarding genetic studies.**
- Vitamin E, 1602–1603
- Vitamin K, 1603–1604
- Zinc, 1612

Diagnostic Tests Associated With the Hepatobiliary System

- Cholangiography, percutaneous transhepatic, 409–414
- Cholangiography, postoperative, 414–418
- Cholangiopancreatography, endoscopic retrograde, 418–422
- Computed tomography, abdomen, 532–537
- Computed tomography, biliary tract and liver, 544–548
- Computed tomography, pancreas, 564–569
- Hepatobiliary scan, 919–923
- Laparoscopy, abdomen, 1023–1026
- Liver and spleen scan, 1040–1044
- Magnetic resonance imaging, abdomen, 1082–1087
- Magnetic resonance cholangiopancreatography (MRCP), 1082–1087
- Magnetic resonance imaging, pancreas, 1107–1111
- Radiofrequency ablation, liver, 1342–1346
- Ultrasound, abdomen, 1478–1480
- Ultrasound, liver and biliary system, 1506–1509

Immune System

Laboratory Tests Associated With the Immune System

- Allergen-specific immunoglobulin E, 39–41
 Amikacin, 154–161
 Angiotensin-converting enzyme, 109–110
 Anion gap, 110
 Antibodies, actin (smooth muscle) and mitochondrial M2, 121
 Antibodies, anti-cyclic citrullinated peptide, 118–120
 Antibodies, antineutrophilic cytoplasmic, 122
 Antibodies, anti-glomerular basement membrane, 120
 Antibodies, antinuclear, anticentromere, anti-DNA, 122–128
 Antibodies, antistreptolysin O, 132
 Antibodies, antithyroglobin and antithyroid peroxidase, 132–133
 Antibodies, cardiolipin, immunoglobulin A, immunoglobulin G, and immunoglobulin M, 133–137
 Antibodies, gliadin (immunoglobulin G and immunoglobulin A), endomysial (immunoglobulin A), tissue transglutaminase (immunoglobulin A), 137–140 **Monograph contains information regarding genetic studies.**
 Antideoxyribonuclease-B, streptococcal, 147
 Antigens/antibodies, antiextractable nuclear, Anti-Jo, antiscleroderma, 122–128
 β_2 -Glycoprotein 1, 134
 β_2 -Microglobulin, 191–197
 Biopsy, bone, 218–221
 Biopsy, bone marrow, 222–227
 Biopsy, breast, 227–232 **Monograph contains information regarding genetic studies.**
 Biopsy, intestinal, 240–242
 Biopsy, kidney, 243–246
 Biopsy, liver, 247–250
 Biopsy, lung, 250–255
 Biopsy, lymph node, 256–259
 Biopsy, muscle, 260–263
 Biopsy, skin, 269–272 **Monograph contains information regarding genetic studies.**
 Biopsy, thyroid, 272–276 **Monograph contains information regarding genetic studies.**
 Bioterrorism and public health safety concerns: testing for toxins and infectious agents, 276–288
 Blood groups and antibodies, 308–315
 Cancer antigens, 358–362 **Monograph contains information regarding genetic studies.**
 CD4/CD8 enumeration, 379–384
 Cerebrospinal fluid analysis, 385–390
Chlamydia group antibody, IgG and IgM, 395–400
 Cold agglutinin titer, 451
 Complement C3 and complement C4, 467–469
 Complement, total, 469–470
 Complete blood count, 470–479
 Complete blood count, hematocrit, 479–485
 Complete blood count, hemoglobin, 486–494
 Complete blood count, platelet count, 495–503 **Monograph contains information regarding genetic studies.**
 Complete blood count, RBC count, 503–509
 Complete blood count, RBC indices, 510–514
 Complete blood count, RBC morphology and inclusions, 514–520
 Complete blood count, WBC count and differential, 520–532
 Copper, 606–607
 C-reactive protein, 620–624
 Cryoglobulin, 644
 Culture and smear, mycobacteria, 644–650
 Culture, bacterial, anal/genital, ear, eye, skin, and wound, 651–656
 Culture, bacterial, blood, 657–661
 Culture, bacterial, sputum, 662–667
 Culture, bacterial, stool, 667–670
 Culture, bacterial, throat or nasopharyngeal, 670–673
 Culture, bacterial, urine, 673–676
 Culture, fungal, 677–679
 Culture, specific body fluid, 677–679
 Culture, synovial fluid, 1411–1415
 Culture, viral, 680–683
 Cytology, sputum, 695–699

(table continues on page 1622)

Laboratory Tests Associated With the Immune System

- Cytology, urine, 700–702
- Cytomegalovirus, immunoglobulin G and immunoglobulin M, 702–706
- Endomysial antibodies, 137–140
- Eosinophil count, 750
- Erythrocyte sedimentation rate, 751–757
- α_1 -Fetoprotein, 789–796
- Genetic testing, 848–852 **Monograph contains information regarding genetic studies.**
- Gentamicin, 154–161
- Gram stain, 884–886
- Group A streptococcal screen, 887–890
- Haptoglobin, 892–894
- Hepatitis A antibody, 904–908
- Hepatitis B antigen and antibody, 908–913
- Hepatitis C antibody, 914–918
- Hepatitis D antibody, 918–919
- Hepatitis E antibody, 919
- Human chorionic gonadotropin, 934–938
- Human immunodeficiency virus type 1 and type 2 antibodies, 939–945
- Human leukocyte antigen B27, 945 **Monograph contains information regarding genetic studies.**
- Human T-lymphotropic virus type I and type II antibodies, 945–946
- 5-Hydroxyindoleacetic acid, 946
- Hypersensitivity pneumonitis, serology, 947
- Immunofixation electrophoresis, blood and urine, 954–958
- Immunoglobulin E, 958–962
- Immunoglobulins A, D, G, and M, 962–967
- Infectious mononucleosis screen, 974–977
- Insulin antibodies, 981–984
- Latex allergy, 1031
- Leukocyte alkaline phosphatase, 1034 **Monograph contains information regarding genetic studies.**
- Lupus anticoagulant antibodies, 1053–1057
- Lyme antibody, 1062–1065
- Mumps serology, 1147–1149
- Ova and parasites, stool, 1203–1207
- Papanicolaou smear, 1209–1216
- Parvovirus B19 immunoglobulin G and immunoglobulin M antibodies, 1230–1231
- Pericardial fluid analysis, 1231–1235
- Peritoneal fluid analysis, 1235–1239
- Platelet antibodies, 1245–1246
- Pleural fluid analysis, 1251–1256
- Potassium, blood, 1277–1285
- Procalcitonin, 1292–1295
- Protein, blood: total and fractions, 1310–1313
- Protein, urine: total quantitative and fractions, 1315–1318
- Rheumatoid factor, 1371–1374
- Rubella antibodies, IgG and IgM, 1375–1379
- Rubeola antibodies, 1379–1381
- Semen analysis, 1384–1387
- Streptococcal screen, rapid, 887–890
- Synovial fluid analysis, 1411–1415
- Syphilis serology, 1415–1420
- Tissue transglutaminase antibodies, 296
- Tobramycin, 154–161
- Toxoplasma* antibody, 1445–1449
- Tuberculosis: skin and blood tests, 1469–1475
- Urinalysis, 1560–1570
- Vancomycin, 139–144
- Varicella, 1579–1582
- Vitamins A, B₁, B₆, and C, 1605–1607
- Zinc, 1612

Diagnostic Tests Associated With the Immune System

- Bronchoscopy, 329–333
- Gallium scan, 826–829
- Liver and spleen scan, 1040–1044
- Lymphangiography, 1065–1070
- Mediastinoscopy, 1133–1137
- Ultrasound, lymph nodes and retroperitoneum, 1509–1511
- White blood cell scan, 1608–1611

Musculoskeletal System

Laboratory Tests Associated With the Musculoskeletal System

Acetylcholine receptor antibody, 1–5	Calcium, urine, 352–353
Aldolase, 27–28	Cerebrospinal fluid analysis, 385–390
Alkaline phosphatase and isoenzymes, 34–38	Collagen cross-linked N-telopeptide, 451–456
Alzheimer's disease markers, 43–46 Monograph contains information regarding genetic studies.	Creatine kinase and isoenzymes, 625–631
Amyloid precursor protein, 43–46	Creatinine, blood, 631–638
Angiotensin-converting enzyme, 109–110	Genetic testing, 848–852
Antibodies, anti-cyclic citrullinated peptide, 118–120	Monograph contains information regarding genetic studies.
Antibodies, antineutrophilic cytoplasmic, 122	Lactate dehydrogenase and isoenzymes, 1012–1013
Antibodies, antinuclear, anti-DNA, and anticentromere, 122–128	Lactic acid, 1013–1018
Antigens/antibodies, anti-extractable nuclear, Anti-Jo, antiscleroderma, 122–128	Lyme antibody, 1062–1065
Apolipoprotein E4 alleles, 43–46	Myoglobin, 1160–1163
Biopsy, bone, 218–221	Osteocalcin, 1200–1201
Biopsy, muscle, 260–263	Phosphorus, blood, 1240–1243
Biopsy, skin, 269–272 Monograph contains information regarding genetic studies.	Presenilin 1 gene, 43–44
Bioterrorism and public health safety concerns: testing for toxins and infectious agents, 276–288	Presenilin 2 gene, 43–44
Calcium, blood, 340–347	Pseudocholinesterase and dibucaine number, 1327–1328
Calcium, ionized, 348–351	Rheumatoid factor, 1371–1374
	Synovial fluid analysis, 1411–1415
	Uric acid, blood, 1553–1559
	Vitamins A, B ₁ , B ₆ , and C, 1605–1607
	Vitamin D, 1597–1602
	Zinc, 1612

Diagnostic Tests Associated With the Musculoskeletal System

Arthrogram, 173–177	Electroneurography, 745–747
Arthroscopy, 177–180	Evoked brain potentials, 769–772
Bone mineral density, 320–324	Magnetic resonance imaging, brain, 1087–1092
Bone scan, 324–328	Magnetic resonance imaging, musculoskeletal, 1102–1107
Computed tomography, brain, 549–554	Positron emission tomography, brain, 1258–1262
Computed tomography, spine, 584–588	Positron emission tomography, FDG, 1262–1267
Computed tomography, xenon enhanced, 549–554	Radiography, bone, 1347–1350
Electroencephalography, 736–739	Vertebroplasty, 1587–1592
Electromyography, 739–742	

Nutritional Considerations

Laboratory Tests With Nutritional Considerations

Albumin and albumin/globulin ratio, 24–27	Magnesium, blood, 1071–1076
Calcium, blood, 340–347	Oxalate, urine, 1207–1208
Chloride, blood, 400–404	Phosphorus, blood, 1240–1243
Cholesterol, HDL and LDL, 423–428	Potassium, blood, 1277–1285
Cholesterol, total, 428–434	Sodium, blood, 1396–1402
Copper, 606–607	Triglycerides, 1452–1459
Folate, 812–816	Uric acid, blood, 1553–1559
Glucose, 853–863 Monograph contains information regarding genetic studies.	Vitamin B ₁₂ , 1595–1597
Insulin and insulin response to glucose, 977–981	Vitamin D, 1597–1602
Iron, 994–1000	Vitamin E, 1602–1603
	Vitamin K, 1603–1604
	Vitamins A, B ₁ , B ₆ , and C, 1605–1607

Ocular System

Laboratory Tests Associated With the Ocular System

Antiarrhythmic drugs: amiodarone, digoxin, disopyramide, flecainide, lidocaine, procainamide, quinidine, 111–117	C-peptide, 617–620
Antibodies, antinuclear, anti-DNA, anticentromere, antiextractable nuclear antigen, and antiscleroderma, 122–128	Culture, bacterial, anal/genital, ear, eye, skin, and wound, 651–656
Anticonvulsant drugs: carbamazepine, ethosuximide, lamotrigine, phenobarbital, phenytoin, primidone, valproic acid, 140–147 Monograph contains information regarding genetic studies.	Fructosamine, 821–822
	Glucagon, 852–853
	Glucose, 853–863 Monograph contains information regarding genetic studies.
	Glycated hemoglobin A _{1c} , 874–880
	Insulin and insulin response to glucose, 977–981
	Microalbumin, 1141–1147
	Rheumatoid factor, 1371–1374
	Vitamins A, B ₁ , B ₆ , and C, 1605–1607

Diagnostic Tests Associated With the Ocular System

Color perception test, 461–463	Nerve fiber analysis, 1164
Computed tomography, brain, 549–554	Pachymetry, 1209
Evoked brain potentials, 769–772	Plethysmography, 1246–1251
Fluorescein angiography, 808–812	Refraction, 1351–1354
Fundus photography, 822–825	Schirmer test, 1382–1384
Gonioscopy, 881–883	Slit-lamp biomicroscopy, 1393–1396
Intraocular muscle function, 984–986	Ultrasound, A-scan, 1489–1491
Intraocular pressure, 986–989	Visual fields test, 1592–1594
Magnetic resonance imaging, brain, 1087–1092	

Reproductive System

Laboratory Tests Associated With the Reproductive System

- Acid phosphatase, prostatic, 5–6
 Amino acid screen, blood, 47–48
Monograph contains information regarding genetic studies.
 Amino acid screen, urine, 48
Monograph contains information regarding genetic studies.
 Amniotic fluid analysis, 54–63
Monograph contains information regarding genetic studies.
 Antibodies, antisperm, 128–131
 Antibodies, cardiolipin, immunoglobulin A, immunoglobulin G, and immunoglobulin M, 133–137
 β_2 -Glycoprotein 1, 134
 Biopsy, breast, 227–232 **Monograph contains information regarding genetic studies.**
 Biopsy, cervical, 232–236
 Biopsy, chorionic villus, 236–239
Monograph contains information regarding genetic studies.
 Cancer antigens, 358–362 **Monograph contains information regarding genetic studies.**
Chlamydia group antibody, IgG and IgM, 395–400
 Chromosome analysis, blood, 435–440
Monograph contains information regarding genetic studies.
 Collagen cross-linked N-telopeptide, 451–456
 Culture, bacterial, anal/genital, 651–656
 Culture, viral, 680–683
 Cytomegalovirus, immunoglobulin G, and immunoglobulin M, 702–706
 Estradiol, 768
 Fern test, 56
 Fetal fibronectin, 787–789
 α_1 -Fetoprotein, 789–796
 Follicle-stimulating hormone, 816–821
 Genetic testing, 848–852
Monograph contains information regarding genetic studies.
 Gram stain, 884–886
 Her-2/neu oncoprotein, 227–228
 Hexosaminidase A and B, 923–924
Monograph contains information regarding genetic studies.
 Human chorionic gonadotropin, 934–938
 Human immunodeficiency virus type 1 and type 2 antibodies, 939–944
 Human papillomavirus, 1211–1212
 Inhibin-A, 792
 Ki67, 228
 Kleihauer-Betke test, 1011

Patient Preparation and Specimen Collection

PATIENT PREPARATION BEFORE DIAGNOSTIC AND LABORATORY PROCEDURES

Successful encounters with patients begin with a professional, respectful, and compassionate approach. Positive communications should begin by addressing the patient using proper titles such as Ms., Mrs., or Mr.; the use of inappropriate terms of endearment is a common patient complaint. First names may be used with the permission of the patient. Health care providers should also always introduce and identify themselves to the patient before explaining the upcoming procedure, when and where the procedure will take place, and the expected duration of the scheduled procedure.

The first step in any laboratory or diagnostic procedure is patient preparation or patient teaching before the performance of the procedure. This pretesting explanation to the patient or caregiver follows essentially the same pattern for all sites and types of studies and includes the following:

- *Statement of the purpose of the study.* The level of detail provided to patients about the test purpose depends on numerous factors and should be individualized appropriately in each particular setting.
- *Description of the procedure, including site and method.* It is a good idea to explain to the patient that you will be wearing gloves throughout the procedure. The explanation should help the patient understand that the use of gloves is standard practice established for his or her protection as well as yours. Many institutions require hand washing at the beginning and end of each specimen collection encounter and between each patient.
- *Description of the sensations, including discomfort and pain, that the patient may experience during the specimen collection procedure.* Address concerns about pain related to the procedure and suggest breathing or visualization techniques to promote relaxation. For pediatric patients, a doll may be used to “show” the procedure. Where appropriate, the use of sedative or anesthetizing agents may assist in allaying anxiety the patient may experience related to anticipation of pain associated with the procedure. Sensitivity to cultural and social issues, as well as concern for modesty, is important in providing psychological support.
- *Instruction regarding pretesting preparations related to diet, liquids, medications, and activity as well as any restrictions regarding diet, liquids, medications, activity, known allergies, therapies, or other procedures that might affect test results.* To increase patient compliance, the instructions should include an explanation of why strict adherence to the instructions is required.
- *Recognition of anxiety related to test results.* Provide a compassionate, reassuring environment. Be prepared to educate the patient regarding access to the appropriate counseling services. Encourage the patient to ask questions and verbalize his or her concerns.

Specific collection techniques and patient preparation vary by site, study required, and level of invasiveness. These techniques are described in the individual monographs.

- It is essential that the patient be positively and properly identified before providing care, treatment, or services. Specimens should always be labeled with the patient's name, date of birth (or some other unique identifier), date collected, time collected, and initials of the person collecting the sample.
- Orders should be completed accurately and submitted per laboratory policy.

BLOOD SPECIMENS

Most laboratory tests that require a blood specimen use venous blood. Venous blood can be collected directly from the vein or by way of capillary puncture. Capillary blood can be obtained from the fingertips or earlobes of adults and small children. Capillary blood can also be obtained from the heels of infants. The circumstances in which the capillary method is selected over direct venipuncture include cases in which:

- The patient has poor veins.
- The patient has small veins.
- The patient has a limited number of available veins.
- The patient has significant anxiety about the venipuncture procedure.

Venous blood also can be obtained from vascular access devices, such as heparin locks and central venous catheters. Examples of central venous catheters include the triple-lumen subclavian, implanted venous access port, and Groshong catheters.

Fetal blood samples can be obtained, when warranted, by a qualified health-care provider (HCP) from the scalp or from the umbilical cord.

Arterial blood can be collected from the radial, brachial, or femoral artery if blood gas analysis is requested.

Some general guidelines should be followed in the procurement and handling of blood specimens:

- The practice of an overnight fast before specimen collection is a general recommendation. Reference ranges are often based on fasting populations to provide some level of standardization for comparison. Some test results are dramatically affected by foods, however, and fasting is a pretest requirement. The presence of lipids in the blood also may interfere with the test method; fasting eliminates this potential source of error, especially if the patient already has elevated lipid levels. The laboratory should always be consulted if there is a question whether fasting is a requirement or a recommendation.
- Gloves and any other additional personal protective equipment indicated by the patient's condition should always be worn during the specimen collection process. Appendix I online at DavisPlus provides a more detailed description of standard precautions.
- Stress can cause variations in some test results. A sleeping patient should be gently awakened and allowed the opportunity to become oriented before collection site selection. Comatose or unconscious patients should be greeted in the same gentle manner because, although they are unable to respond, they may be capable of hearing and understanding. Anticipate instances in which patient cooperation may be an issue. Enlist a second person to assist with specimen collection to ensure a safe, quality collection experience for all involved.
- Localized activity such as the application of a tourniquet or clenching the hand to assist in visualizing the vein can cause variations in some test results. It is important to be aware of affected studies before specimen collection.

- Hemoconcentration may cause variations in some test results. The tourniquet should never be left in place for longer than 1 min.
- Previous puncture sites should be avoided when accessing a blood vessel by any means to reduce the potential for infection.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. It is also possible that substances in the IV solution could contaminate the specimen and result in falsely elevated test results.
- Changes in posture from supine to erect or long-term maintenance of a supine posture causes variations in some test results. It is important to be aware of this effect when results are interpreted and compared with previous values.
- Collection times for therapeutic drug (peak and trough) or other specific monitoring (e.g., chemotherapy, glucose, insulin, or potassium) should be documented carefully in relation to the time of medication administration. It is essential that this information be communicated clearly and accurately to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in the calculation of future therapies.
- The laboratory should be consulted regarding minimum specimen collection requirements when multiple tube types or samples are required. The amount of serum or plasma collected can be estimated using assumptions of packed cell volume or hematocrit. The packed cell volume of a healthy woman is usually 38% to 44% of the total blood volume. If a full 5-mL red-top tube is collected, and the hematocrit is 38% to 44%, approximately 2.8 to 3.1 mL, or $[5 - (5 \times 0.44)]$ to $[5 - (5 \times 0.38)]$, of the total blood volume should be serum. Factors that invalidate estimation include conditions such as anemia, polycythemia, dehydration, and overhydration.
- The laboratory should be consulted regarding the preferred specimen container before specimen collection. Specific analytes may vary in concentration depending on whether the sample is serum or plasma. It is strongly recommended that when serial measurements are to be carried out, the same type of collection container be used so that fluctuations in values caused by variations in specimen type are not misinterpreted as changes in clinical status. Consultation regarding collection containers is also important because some laboratory methods are optimized for a specific specimen type (serum versus plasma). Also, preservatives present in collection containers, such as sodium fluoride, may exhibit a chemical interference with test reagents that can cause underestimation or overestimation of measured values. Other preservatives, such as EDTA, can block the analyte of interest in the sample from participating in the test reaction, invalidating test results. Finally, it is possible that some high-throughput, robotic equipment systems require specific and standardized collection containers.
- Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. Specimens collected in containers with solid or liquid preservatives or with gel separators should be mixed by inverting the tube 10 times immediately after the tube has been filled. Handle the specimen

gently to avoid hemolysis. Specimens should always be transported to the laboratory as quickly as possible after collection.

- Results that are evaluated outside the entire context of the preparatory, collection, and handling process may be interpreted erroneously if consideration is not given to the above-listed general guidelines.

Site Selection

Capillary Puncture: Assess the selected area. It should be free of lesions and caluses, there should be no edema, and the site should feel warm. If the site feels cool or appears pale or cyanotic, warm compresses can be applied over 3 to 5 min to dilate the capillaries. For fingersticks, the central, fleshy, distal portions of the third or fourth fingers are the preferred collection sites (Fig. A-1). For neonatal heel sticks, the medial and lateral surfaces of the plantar area are preferred to avoid direct puncture of the heel bone, which could result in osteomyelitis (Fig. A-2).

Venipuncture of Arm: Assess the arm for visibly accessible veins. The selected area should not be burned or scarred, have a tattoo, or have hematoma present. Even after the tourniquet is applied, not all patients have a prominent median cubital, cephalic, or basilic vein. Both arms should be observed because some

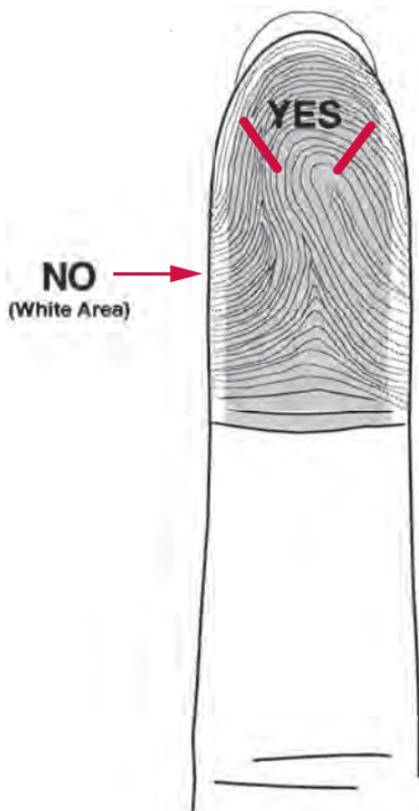

Figure A-1 Site selection. Capillary puncture of the finger.

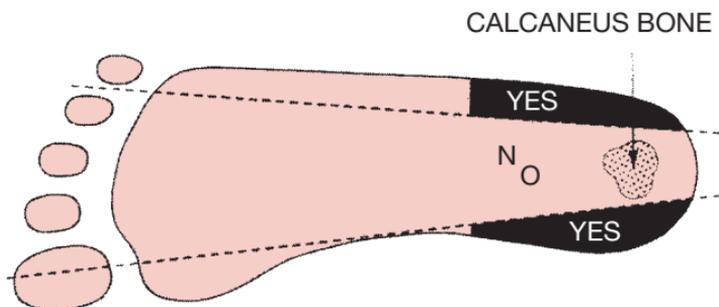

Figure A-2 Site selection. Capillary puncture of the heel.

patients have accessible veins in one arm and not the other. The median cubital vein in the antecubital fossa is the preferred venipuncture site. The patient may be able to provide the best information regarding venous access if he or she has had previous venipuncture experience (Fig. A-3). Alternative techniques to increase visibility of veins may include warming the arm, allowing the arm to dangle downward for a minute or two, tapping the antecubital area with the index finger, or massaging the arm upward from wrist to elbow. The condition of the vein also should be assessed before venipuncture. Sclerotic (hard, scarred) veins or veins in which phlebitis previously occurred should be avoided. Arms with a functioning hemodialysis access site should not be used. The arm on the affected side of a mastectomy should be avoided. In the case of a double mastectomy, the requesting HCP should be consulted before specimen collection.

Venipuncture of Hand and Wrist: If no veins in the arms are available, hands and wrists should be examined as described for the arm (see Fig. A-3). Consideration should be given to the venipuncture equipment selected because the veins in these areas are much smaller. Pediatric-sized collection containers and needles with a larger gauge may be more appropriate.

Venipuncture of Legs and Feet: The veins in the legs and feet can be accessed with sites located on the arm, hand, or wrist. These extremities should be used only on the approval of the requesting HCP because veins in these locations are more prone to infection and formation of blood clots, especially in patients with diabetes, cardiac disease, and bleeding disorders.

Radial Arterial Puncture: The radial artery is the artery of choice for obtaining arterial blood gas specimens because it is close to the surface of the wrist and does not require a deep puncture. Its easy access also allows for more effective compression after the needle has been removed. The nearby ulnar artery can provide sufficient collateral circulation to the hand during specimen collection and postcollection compression (Fig. A-4).

Percutaneous Umbilical Cord Sampling: The blood is aspirated from the umbilical cord under the guidance of ultrasonography and using a 20- or 22-gauge spinal needle inserted through the mother's abdomen.

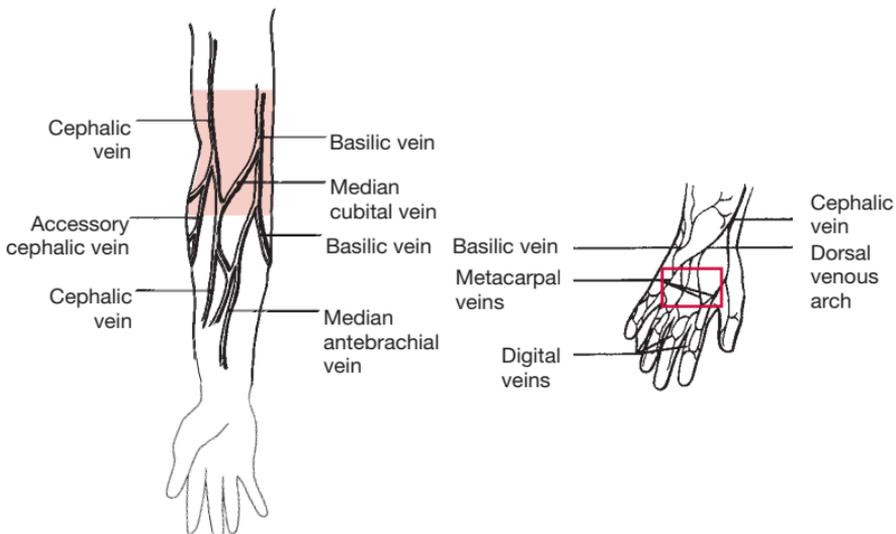

Figure A-3 Site selection. Venipuncture arm/hand.

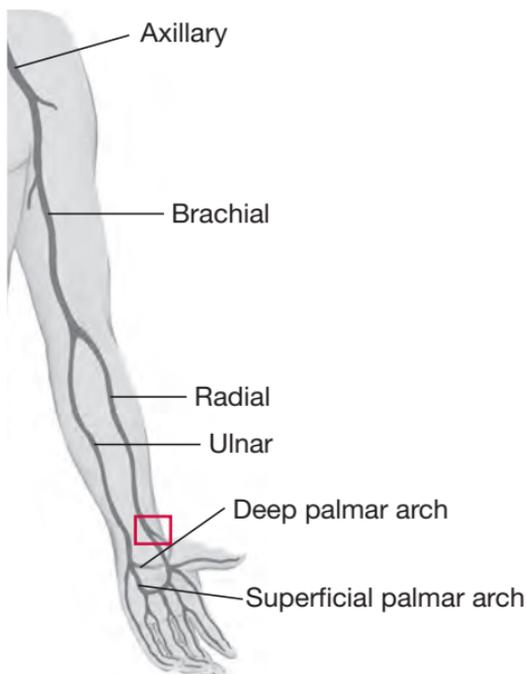

Figure A-4 Site selection. Arterial arm/hand.

Postnatal Umbilical Cord Sampling: The blood is aspirated from the umbilical cord using a 20- or 22-gauge needle and transferred to the appropriate collection container.

Fetal Scalp Sampling: The requesting HCP makes a puncture in the fetal scalp using a microblade, and the specimen is collected in a long capillary tube. The tube is usually capped on both ends immediately after specimen collection.

Locks and Catheters: These devices are sometimes inserted to provide a means for the administration of fluids or medications and to obtain blood specimens without the need for frequent venipuncture. The device first should be assessed for patency. The need for heparinization, irrigation, or clot removal depends on the type of device in use and the institution-specific or HCP-specific protocols in effect. Use sterile technique because these devices provide direct access to the patient's bloodstream. When IV fluids are being administered via a device at the time of specimen collection, blood should be obtained from the opposite side of the body. If this is not possible, the flow should be stopped for 5 min before specimen collection. The first 5 mL of blood collected should be discarded.

Selection of Blood Collection Equipment

In many cases when a blood sample is required, serum is the specimen type of choice. Plasma may be frequently substituted, however. Specimen processing is more rapid for plasma samples than serum samples because the anticoagulated sample does not need to clot before centrifugation. Plasma samples also require less centrifugation time to achieve adequate separation. Consult with the testing laboratory regarding recommended specimen types. The basic blood collection tubes are shown on the inside cover of this book. Consider latex allergy when selecting the collection equipment appropriate for each patient. Equipment used in specimen collection includes:

- Gloves and other personal protective equipment depending on the situation
- Tourniquet
- Materials to cleanse or disinfect the collection site (alcohol preparations [70% alcohol], povidone-iodine solution [Betadine], or green soap are the most commonly used materials)
- Gauze (to wipe collection site dry after cleansing)
- Sterile lancet (capillary puncture)
- Syringe and needle (arterial puncture or venipuncture)
- Vial of heparin and syringe or heparin unit dose
- Sterile normal saline in 50-mL syringe (for indwelling devices such as Groshong catheter)
- Sterile cap or hub (for indwelling devices when the cap or hub will be replaced after specimen procurement)
- Needle and holder for vacuumized collection tube system (arterial puncture or venipuncture)
- Butterfly or winged infusion set (venipuncture)
- Collection container (vacuumized collection tube, capillary tube, or Microtainer)
- Bandage (to cover puncture site after specimen collection)

Collection Procedure

The procedures outlined here are basic in description. Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected.

Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

Pediatric and Geriatric Considerations: Two venipuncture-related concerns that are especially important pertain to the selection of specimen collection materials and the volume of specimen required.

- Iatrogenic anemia is a significant concern for hospitalized infants. Anemia from chronic blood sampling can also be an issue for older adults who may also suffer malnutrition, dehydration, and diminished hematopoietic system response. The use of Microtainers allows for specimen collection from capillary sites. Many vacuum tubes, including blood culture tubes, are available in pediatric sizes to reduce collection volume. Advances in the technology of laboratory equipment has dramatically reduced, to microsamples, the amount of specimen required for testing.
- There have been other changes in equipment used specifically to address specimen collection issues in the pediatric and geriatric populations. The use of butterfly needles or winged infusion sets has become very popular with older adults who believe “they hurt less and are smaller” than conventional needles. Smaller needle size is a patient perception; butterfly and vacutainer holder needles are available in the same sizes. The way the butterfly needle is designed is the reason the patient perceives a less painful venipuncture. The butterfly wings are held by the phlebotomist and because the wings are closer to the needle than with a traditional vacutainer holder, the needle can be placed with greater precision; the tubing also allows for greater freedom and mobility in site selection to include surface veins (hand, wrist, scalp) that tend to “roll” when a traditional vacutainer holder is used. The skin of pediatric and geriatric patients is very delicate and tape was typically used to hold the bandage in place after the venipuncture. Many patients could not even tolerate the paper tape that is made with less adhesive. A self-adhesive wrap is now commonly used instead of tape; a section of the wrap is placed over the bandage and then the roll of adhesive is wrapped several times around the bandage. The wrap sticks to itself instead of the skin, very effectively holds the bandage in place, comes in every color imaginable, and is very popular with patients.

Complications: There are a number of complications associated with invasive punctures of the skin. Pain is commonly associated with needles and while pain experienced during a needle puncture is usually mild, on a rare occasion the needle may strike a nerve causing severe and lasting pain. Hematoma results when blood leaks into the tissue during or after a needle puncture as evidenced by pain, bruising, and/or swelling at the puncture site. The swelling can cause temporary or permanent injury by compressing the surrounding nerves. Hematomas occur more often in elderly or frail patients, or those with difficult vessels to access. Prolonged bleeding is a complication that occurs with patients who are taking blood thinners such as aspirin or warfarin, or who have coagulopathies such as hemophilia. Bleeding or bruising can be prevented by applying direct pressure to the puncture site, once the needle has been removed, with gauze for a minute or two. The site should then be observed/assessed for bleeding or bruising. If no further action is required, the site can be covered by the gauze and an adhesive bandage or paper tape. Some patients experience a vasovagal reaction during the needle puncture procedure, evidenced by sweating (diaphoresis), low blood pressure (hypotension), fainting

(syncope), or near fainting (near syncope). The potential for a fall injury is a significant concern related to vasovagal reactions. Other more unusual complications of needle puncture include cellulitis, phlebitis, seizures, inadvertent arterial puncture during a venipuncture, and sepsis. Sepsis can be caused by introduction of bacteria from the surface of the skin into the blood as the result of improper cleansing of the puncture site. Immunocompromised patients are at higher risk for developing this complication.

Capillary: Place the patient in a comfortable position either sitting or lying down. Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected. Assess whether the patient has allergies to the disinfectant or to latex if latex gloves or tourniquet will be used in the collection procedure. Use gloved hands to select the collection site as described in the site selection section. Cleanse the skin with the appropriate disinfectant and dry the area. Pull the skin tight by the thumb and index finger of the nondominant hand on either side of the puncture site and move them in opposite directions. Puncture the skin with a sterile lancet to a depth of approximately 2 mm, using a quick, firm motion. Wipe the first drop of blood away using the gauze. If flow is poor, the site should not be squeezed or the specimen may become contaminated with tissue fluid. Do not allow the collection container to touch the puncture site. Collect the sample in the capillary tube or Microtainer. The capillary tube should be held in a horizontal position to avoid the introduction of air bubbles into the sample. Microtainer tubes should be held in a downward-slanted direction to facilitate the flow of blood into the capillary scoop of the collection device. If a smear is required, allow a drop of blood to fall onto a clean microscope slide. Gently spread the drop across the slide using the edge of another slide. Apply slight pressure to the puncture site with a clean piece of gauze until bleeding stops, and then apply a bandage. Safely dispose of the sharps. Transport properly labeled specimens immediately to the laboratory.

Venipuncture Using a Syringe or Vacuumized Needle and Holder System: Place the patient in a comfortable position either sitting or lying down. Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected. Assess whether the patient has allergies to the disinfectant or to latex if latex gloves or tourniquet will be used in the collection procedure. Use gloved hands to select the collection site as described in the Site Selection section. Locate the vein visually, then by palpation using the index finger. The thumb should not be used because it has a pulse beat and may cause confusion in site selection or in differentiating a vein from an artery. Select the appropriate collection materials (needle size, butterfly, syringe, collection container size) on the basis of the vein size, vein depth, appearance of the collection site, patient's age, and anticipated level of cooperation. Cleanse the skin with the appropriate disinfectant and dry the area. Select the appropriate collection tubes. If blood cultures are to be collected, disinfect the top of the collection containers as directed by the testing laboratory. Be sure to have extra tubes within easy reach in case the vacuum in a collection tube is lost and a substitute is required. Apply the tourniquet 3 to 4 in. above the selected collection site. Remove the sterile needle cap, and inspect

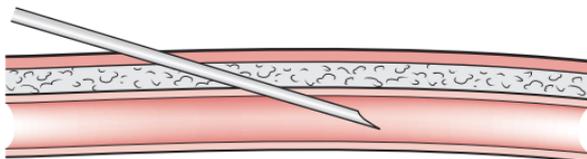

Figure A-5 Venipuncture needle placement at insertion.

the tip of the needle for defects. Pull the skin tight by placing the thumb of the nondominant hand 1 or 2 in. below the puncture site and moving the thumb in the opposite direction. The thumb is placed below the puncture site to help avoid an accidental needle stick if the patient moves suddenly. Ensure that the needle is bevel up and held at an angle of approximately 15° to 30° (depending on the depth of the vein) (Fig. A-5).

Puncture the skin with a smooth, firm motion using a sterile needle held by the dominant hand. A reduction in pressure is achieved when the needle has penetrated the vein successfully. Be sure to release the tourniquet within 1 min of application. Fill the vacuumized collection containers in the prescribed order of draw for the studies ordered. Tubes with anticoagulants can be gently mixed with the free nondominant hand as they are filled. When the required containers have been filled, withdraw the needle and apply pressure to the collection site until the bleeding stops. In most cases, a piece of gauze can be placed on the collection site and the arm bent upward to hold it in place while attention is given to disposing of the sharps safely. In cases in which a syringe is used, the barrel of the syringe should be gently pulled back during specimen collection and gently pushed in during the transfer to collection tubes. The vacuum in the collection container should not be allowed to suck the sample into the container, but rather the speed of entry should be controlled by the pressure applied to the barrel. The blood should gently roll down the side of the tube to prevent hemolysis. Transport properly labeled specimens immediately to the laboratory.

Radial Artery Puncture: Place the patient in a comfortable position either sitting or lying down. Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected. Assess whether the patient has allergies to the disinfectant or to latex if latex gloves or tourniquet will be used in the collection procedure. Assess if the patient has an allergy to local anesthetics, and inform the HCP accordingly. Glove the hands, and select the collection site as described in the site selection section. Ensure that the patient has adequate collateral circulation to the hand if thrombosis of the radial artery occurs after arterial puncture by performing an Allen test before puncture. The Allen test is performed by occlusion of the ulnar and radial arteries on the palmar surface of the wrist with two fingers. The thumb should not be used to locate these arteries because it has a pulse. Compress both arteries, and ask the patient to open and close the fist several times until the palm turns pale. Release pressure only on the ulnar artery. Color should return to the palm within 5 sec if the ulnar artery is functioning. If color returns above the wrist, the Allen test is positive. The Allen test also should be performed on the opposite hand. The wrist to which color is restored fastest has better circulation and should be selected as the site for blood gas collection. Be sure to explain to the patient that an arterial puncture

is painful. The site may be anesthetized with 1% to 2% lidocaine (Xylocaine) before puncture. The index finger of the nondominant hand is placed over the site where the needle will enter the artery, not the site where the needle will penetrate the skin. The specimen is collected in an air-free heparinized syringe, which is held like a dart in the dominant hand and inserted slowly, bevel up, about 5 to 10 mm below the palpating finger at a 45° to 60° angle. When blood enters the needle hub, arterial pressure should cause blood to pump into the syringe. When enough specimen has been collected, the needle is withdrawn from the arm, and pressure is applied to the collection site for a minimum of 5 to 10 min. Immediately after the needle has been withdrawn safely from the arm, the exposed end of the syringe should be stoppered.

Samples should be gently and well mixed to ensure proper mixing of the heparin with the sample. The heparin prevents formation of small clots that result in rejection of the sample. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Transport properly labeled specimens immediately to the laboratory.

Indwelling Devices: Positively identify the patient using at least two unique identifiers before providing care, treatment, or services. Label the appropriate tubes with the corresponding patient demographics, date, and time of collection before the specimen is collected. Indwelling devices are either heparinized or irrigated after specimen collection. Before specimen collection, prepare the heparin in a syringe, if required. Allow the heparin (unit dose or prepared solution in the syringe) to equilibrate at room temperature during specimen collection. Cleanse the catheter cap or hub with povidone-iodine and 70% alcohol over 2 min. Using sterile gloves, remove the cap and attach a 5- or 10-mL syringe to the connector. Withdraw 5 mL of blood to be discarded. Clamp the catheter. (The Groshong catheter does not require clamping because it has a special valve that eliminates the need for clamping.) Attach another 5- or 10-mL syringe and begin collecting blood for transfer to the collection tubes. After the required specimen has been withdrawn, the device is heparinized by slowly injecting the heparin into the cap or hub of the device. Clamp the device 2 in. from the cap, remove the needle, and unclamp the device. Attach a new sterile cap or hub if the old one has been discarded. Groshong catheters are irrigated rather than heparinized. Irrigation of a Groshong catheter is accomplished by gently injecting 20 to 30 mL of sterile normal saline through the cap with moderate force. Remove the needle using some positive pressure (pressing down on the plunger) to prevent the solution from backing up into the syringe. Transport properly labeled specimens immediately to the laboratory.

Order of Draw for Glass or Plastic Tubes (Reflects Current CLSI [formerly NCCLS] Guideline: Procedures for the Collection of Diagnostic Blood Specimens by Venipuncture, GP41-A6, Sixth Edition)

Note: Always follow your facility's protocol for order of draw.

- First—Blood culture and other tests requiring sterile specimen (yellow or yellow/black stopper); blood culture bottle first, followed by sodium polyethanol sulfonate (SPS) tube for acid-fast bacilli specimens.
- Second—Coagulation studies (light blue [sodium citrate] stopper); sodium citrate forms calcium salts to remove calcium, and this prevents specimen

clotting. *Note:* When using a winged blood or vacutainer collection set and the blue-top tube is the first tube drawn, a nonadditive red-top or coagulation discard tube should be collected first and discarded. The amount of blood in the discard tube needs to be sufficient to fill the winged collection set tubing's "dead space" or fill one-quarter of the discard tube. This is done to ensure complete filling of the blue-top tube. The blue-top tube to be used for testing must be filled to ensure the proper ratio of blood to additive in the test specimen blue-top tube.

- Third—Plain or nonadditive (red or red/gray [gel] stopper); red/gray-top serum separator tube (SST) contains a gel separator and clot activator. SSTs are not appropriate for all testing requiring a serum specimen. They are generally unacceptable for therapeutic drug monitoring and serology studies. The laboratory should be consulted if there are questions regarding the use of SSTs.
- Fourth—Additive tubes in the following order:

Green stopper: Tube contains sodium heparin or lithium heparin anticoagulant (heparin inactivates thrombin and thromboplastin, and this prevents specimen clotting). For ammonia levels, use sodium or lithium heparin. For lithium levels, use sodium heparin.

Lavender stopper: Tube contains K_3 EDTA (tripotassium EDTA forms calcium salts to remove calcium from the sample, and this prevents specimen clotting while preserving the integrity of the red blood cell wall).

White stopper: Tube contains K_3 EDTA with gel (this preservative is intended for polymerase chain reaction [PCR] and branched DNA amplification [bDNA] techniques used in molecular diagnostics testing).

Blue/black stopper: Tube contains sodium citrate or sodium heparin with gel (this tube should be collected after EDTA but before any tube containing a liquid additive; this tube is intended for separation and harvesting of mononuclear cells from the whole blood matrix for use in molecular diagnostics testing).

Gray stopper: Tube contains potassium oxalate/sodium fluoride (the potassium oxalate acts as an anticoagulant, and the sodium fluoride prevents glycolysis).

Clear stopper: Tube contains PAXgene blood RNA preservative solution (this tube should always be collected last, and if no other tubes are collected, a discard tube should be collected first and discarded; this tube is preferred for subsequent isolation and purification of intracellular RNA from whole blood for PCR used in molecular diagnostics testing).

URINE SPECIMENS

The patient should be informed that improper collection, storage, and transport are the primary reasons for specimen rejection and subsequent requests for recollection. If the specimen is to be collected at home, it should be collected in a clean plastic container (preferably a container from the testing laboratory). Many studies require refrigeration after collection. If the collection container includes a preservative, the patient should be made aware of the contents and advised as to what the precaution labels mean (caution labels such as caustic, corrosive, acid, and base should be affixed to the container as appropriate). When a preservative or fixative is included in the container, the patient should be advised not to remove it. The patient also should be told not to void directly into the container. The patient should be given a collection device, if indicated, and instructed to void into the collection device. The specimen should be carefully transferred into the collection container. Urinary output should be recorded throughout the collection time if the specimen is

being collected over a specified time interval. Some laboratories provide pre-printed collection instructions tailored to their methods. The specimen should be transported promptly to the laboratory after collection.

Wear gloves and any other additional personal protective equipment indicated by the patient's condition. See Appendix I online at DavisPlus for a more detailed description of standard precautions. Assess whether the patient has allergies to the disinfectant or anesthetic, or to latex if latex gloves or catheter will be used in the procedure.

Random: These samples are mainly used for routine screening and can be collected at any time of the day. The patient should be instructed to void either directly into the collection container (if there is no preservative) or into a collection device for transfer into the specimen container.

First Morning: Urine on rising in the morning is very concentrated. These specimens are indicated when screening for substances that may not be detectable in a more dilute random sample. These specimens are also necessary for testing conditions such as orthostatic proteinuria, in which levels vary with changes in posture.

Second Void: In some cases, it is desirable to test freshly produced urine to evaluate the patient's current status, as with glucose and ketones. Explain to the patient that he or she should first void and then drink a glass of water. The patient should be instructed to wait 30 min and then void either directly into the collection container or into a collection device for transfer into the collection container.

Clean Catch: These midstream specimens are generally used for microbiological or cytological studies. They also may be requested for routine urinalysis to provide a specimen that is least contaminated with urethral cells, microorganisms, mucus, or other substances that may affect the interpretation of results. Instruct the male patient first to wash hands thoroughly, then cleanse the meatus, void a small amount into the toilet, and void either directly into the specimen container or into a collection device for transfer into the specimen container. Instruct the female patient first to wash hands thoroughly, and then to cleanse the labia from front to back. While keeping the labia separated, the patient should void a small amount into the toilet, and then, without interrupting the urine stream, void either directly into the specimen container or into a collection device for transfer into the specimen container.

Catheterized Random or Clean Catch: "Straight catheterization" is indicated when the patient is unable to void, when the patient is unable to prepare properly for clean-catch specimen collection, or when the patient has an indwelling catheter in place from which a urine sample may be obtained. Before collecting a specimen from the catheter, observe the drainage tube to ensure that it is empty, and then clamp the tube distal to the collection port 15 min before specimen collection. Cleanse the port with an antiseptic swab such as 70% alcohol and allow the port to dry. Use a needle and syringe (sterile if indicated) to withdraw the required amount of specimen. Unclamp the tube.

Timed: To quantify substances in urine, 24-hr urine collections are used. They are also used to measure substances whose level of excretion varies over time. The use of preservatives and the handling of specimens during the timed collection may be subject to variability among laboratories. The testing laboratory should

be consulted regarding specific instructions before starting the test. Many times the specimen must be refrigerated or kept on ice throughout the entire collection period. Explain to the patient that it is crucial for all urine to be included in the collection. Urinary output should be recorded throughout the collection time if the specimen is being collected over a specified time interval. The test should begin between 6 and 8 a.m. if possible. Instruct the patient to collect the first void of the day and discard it. The start time of the collection period begins at the time the first voided specimen was discarded and should be recorded along with the date on the collection container. The patient should be instructed to void at the same time the following morning and to add this last voiding to the container. This is the end time of the collection and should be recorded along with the date on the container. For patients who are in the hospital, the urinary output should be compared with the volume measured in the completed collection container. Discrepancies between the two volumes indicate that a collection might have been discarded. A creatinine level often is requested along with the study of interest to evaluate the completeness of the collection.

Catheterized Timed: Instructions for this type of collection are basically the same as those for timed specimen collection. The test should begin by changing the tubing and drainage bag. If a preservative is required, it can be placed directly in the drainage bag, or the specimen can be removed at frequent intervals (every 2 hr) and transferred to the collection container to which the preservative has been added. The drainage bag must be kept on ice or emptied periodically into the collection container during the entire collection period if indicated by the testing laboratory. The tubing should be monitored throughout the collection period to ensure continued drainage.

Suprapubic Aspiration: This procedure is performed by inserting a needle directly into the bladder. Because the bladder is normally sterile, the urine collected should also be free from any contamination caused by the presence of microorganisms. Place the patient in a supine position. Cleanse the area with antiseptic and drape with sterile drapes. A local anesthetic may be administered before insertion of the needle. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container. The site must be observed for signs of inflammation or infection.

Pediatric: Specimen collection can be achieved by any of the above-described methods using collection devices specifically designed for pediatric patients. Appropriately cleanse the genital area and allow the area to dry. For a random collection, remove the covering of the adhesive strips on the collector bag and apply over the genital area. Diaper the child. When the specimen is obtained, place the entire collection bag in the specimen container (use a sterile container as appropriate for the requested study). Some laboratories may have specific preferences for the submission of urine specimens for culture. Consult the laboratory before collection to avoid specimen rejection.

BODY FLUID, STOOL, AND TISSUE

Wear gloves and any other additional personal protective equipment indicated by the patient's condition. See Appendix I online at DavisPlus for a more detailed description of standard precautions. Assess whether the

patient has allergies to the disinfectant or anesthetic or to latex if latex gloves will be used in the procedure.

Specific collection techniques vary by site, study required, and level of invasiveness. These techniques are described in the individual monographs.

DIAGNOSTIC TESTING

Wear gloves and any other additional personal protective equipment indicated by the patient's condition. See Appendix I online at DavisPlus for a more detailed description of standard precautions. Assess whether the patient has allergies to the disinfectant, anesthetic, contrast material, or medications or to latex if latex gloves, catheter, or tourniquet will be used in the procedure.

A sleeping patient should be gently awakened and allowed the opportunity to become oriented before preparation for the selected study. Comatose or unconscious patients should be greeted in the same gentle manner because, although they are unable to respond, they may be capable of hearing and understanding. Anticipate instances in which patient cooperation may be an issue. Enlist a second person to help with preparing the patient for the procedure to ensure a safe, quality testing experience for all involved.

Specific techniques and patient preparation vary by site, study required, age of the patient, and level of invasiveness. These techniques are described in the individual monographs. The pediatric, maternity, special needs, and geriatric patient populations require special considerations when preparing for diagnostic studies.

Pediatric Considerations Preparing children for a diagnostic study depends on the age of the child. Encourage parents to be truthful about unpleasant sensations (cramping, pressure, pinching, etc.) the child may experience during the procedure and to use words that they know their child will understand. Toddlers and preschool-age children have a very short attention span, so the best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with the child during the procedure. Special equipment (e.g., balloon-tip catheters to assist with retention of barium during a barium enema, foam wedges used to hold a limb in place during a nuclear scan, etc.) may be needed to assist with a successful study. Postprocedural recovery interventions, such as achieving adequate hydration, require close attention. The parents or caregivers must receive education to help them address specific needs and to be watchful for indications of a developing problem because pediatric patients cannot do these things for themselves.

Geriatric Considerations Elderly patients present with a variety of concerns when undergoing diagnostic procedures. Level of cooperation and fall risk may be complicated by underlying problems such as visual and hearing impairment, joint and muscle stiffness, physical weakness, mental confusion, and the effects of medications. A fall injury can be avoided by providing assistance getting on and off the examination table and getting on and off the toilet before and at the end of the exam. Older patients who are small in size compared to other adults also may receive a higher radiation dose than necessary if settings are not adjusted for their size. Elderly patients are often chronically dehydrated; anticipating the effects of hypovolemia and orthostasis can also help prevent falls. Special equipment (e.g., balloon-tip catheters to assist with retention of barium during a barium enema, foam wedges used to hold a limb in place during a nuclear scan, etc.) may be needed to assist with a successful study. Postprocedural recovery interventions,

such as achieving adequate hydration, require close attention. Many older patients wish to maintain their independence. Their caregivers must receive education to help them address specific needs and to be watchful for indications of a developing problem; the limits of an older patient's physical and mental abilities may be an obstacle to independently carrying out the proper postprocedural care.

Radiation Safety Consultation with a HCP should occur before procedures involving radiation to discuss safety concerns regarding younger patients or patients who are lactating.

Pediatric Imaging Radiation risk is higher in young patients as they have more rapidly dividing cells than adults, and radiation damage occurs during cell division. Therefore, the younger the patient, the more radiation-sensitive the patient is. The Image Gently Campaign is an initiative of the Alliance for Radiation Safety in Pediatric Imaging. Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/). The campaign goal is to change practice by increasing awareness of the opportunities to promote radiation protection in the imaging of children. Three unique considerations in pediatric imaging are as follows:

- Children are considerably more sensitive to radiation than adults, which is evidenced in epidemiologic studies of exposed populations.
- Children have a longer life expectancy than adults, resulting in a larger window of opportunity for showing radiation damage.
- Children may receive a higher radiation dose than necessary if settings are not adjusted for their small size.

In addition to radiation safety, there are risks associated with the use of contrast media, especially iodinated contrast mediums. Pediatric patients have immature or incompletely developed organ and immune systems that do not tolerate the rigors of diagnostic testing as well as adults. Older adults are also potentially less able to tolerate some procedures because their systems are weakened by the natural aging process and interactions that may occur due to the presence of complex multisystem diseases.

- Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
- If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).

Laboratory Critical Findings

Monograph Title	Critical Finding (Conventional Units)	Conversion Factor	Critical Finding (SI)
Therapeutic Drugs			
<i>Analgesic and Antipyretic Drugs</i>			
Acetaminophen	Greater than 200 mcg/mL (4 hr post-ingestion)	SI = CU × 6.62	Greater than 1,324 micromol/L (4 hr postingestion)
Acetylsalicylic acid	Greater than 40 mg/dL	SI = CU × 0.073	Greater than 2.9 mmol/L
<i>Antiarrhythmic Drugs</i>			
Amiodarone	Greater than 2.5 mcg/mL	SI = CU × 1.55	Greater than 3.9 micromol/L
Digoxin	Greater than 2.5 ng/mL	SI = CU × 1.28	Greater than 3.2 nmol/L
Disopyramide	Greater than 7 mcg/mL	SI = CU × 2.95	Greater than 20.6 micromol/L
Flecainide	Greater than 1 mcg/mL	SI = CU × 2.41	Greater than 2.41 micromol/L
Lidocaine	Greater than 6 mcg/mL	SI = CU × 4.27	Greater than 25.6 micromol/L
Procainamide	Greater than 10 mcg/ mL	SI = CU × 4.25	Greater than 42.5 micromol/L
N-Acetyl Procainamide	Greater than 40 mcg/ mL	SI = CU × 4.25	Greater than 170 micromol/L
Quinidine	Greater than 6 mcg/mL	SI = CU × 3.08	Greater than 18.5 micromol/L
<i>Anticonvulsant Drugs</i>			
Carbamazepine	Greater than 20 mcg/ mL	SI = CU × 4.23	Greater than 85 micromol/L
Ethosuximide	Greater than 200 mcg/mL	SI = CU × 7.08	Greater than 1,416 micromol/L
Lamotrigine	Greater than 20 mcg/ mL	SI = CU × 3.9	Greater than 78 micromol/L
Phenobarbital	Greater than 60 mcg/ mL	SI = CU × 4.31	Greater than 259 micromol/L
Phenytoin	Greater than 40 mcg/ mL	SI = CU × 3.96	Greater than 158 micromol/L
Primidone	Greater than 15 mcg/ mL	SI = CU × 4.58	Greater than 69 micromol/L
Valproic Acid	Greater than 200 mcg/mL	SI = CU × 6.93	Greater than 1,386 micromol/L

Fibrinogen	Less than 80 mg/dL	SI = CU × 0.0294	Less than 2.4 micromol/L
Glucose	<i>Adults & children</i> : less than 40 mg/dL; greater than 400 mg/dL; <i>newborns</i> : less than 32 mg/dL; greater than 328 mg/dL	SI = CU × 0.0555	<i>Adults & children</i> : less than 2.22 mmol/L; greater than 22.2 mmol/L; <i>newborns</i> : less than 1.8 mmol/L; greater than 18.2 mmol/L
Gram Stain	Any positive results in blood, cerebrospinal fluid, or any body cavity fluid	N/A	

Monograph Title	Critical Finding (Conventional Units)	Conversion Factor	Critical Finding (SI)
Iron	Serious toxicity: greater than 400 mcg/dL; lethal: greater than 1,000 mcg/dL	SI = CU × 0.179	Serious toxicity: greater than 71.6 micromol/L; lethal: greater than 179 micromol/L
Ketones, Blood and Urine	Strongly positive test results for ketones	N/A	
Lactic Acid	<i>Adults</i> : greater than 31 mg/dL; <i>children</i> : greater than 37 mg/dL	SI = CU × 0.111	<i>Adults</i> : greater than 3.4 mmol/L; <i>children</i> : greater than 4.1 mmol/L
Lead	Levels greater than 30 mcg/dL indicate significant exposure; levels greater than 60 mcg/dL may require chelation therapy	SI = CU × 0.0483	Levels greater than 1.4 micromol/L indicate significant exposure; levels greater than 2.9 micromol/L may require chelation therapy
Magnesium, Blood	<i>Adults</i> : less than 1.2 mg/dL; greater than 4.9 mg/dL; <i>children</i> : less than 1.2 mg/dL; greater than 4.3 mg/dL	SI = CU × 0.4114	<i>Adults</i> : less than 0.5 mmol/L; greater than 2 mmol/L; <i>children</i> : less than 0.5 mmol/L; greater than 1.8 mmol/L
Methemoglobin	Signs of central nervous system depression can occur at levels greater than 45%; death may occur at levels greater than 70%	N/A	
Osmolality, Blood	Less than 265 mOsm/kg; greater than 320 mOsm/kg	SI = CU × 1	Less than 265 mmol/kg; greater than 320 mmol/kg
Partial Thromboplastin Time (PTT)	<i>Adults & children</i> : Greater than 70 sec	N/A	
Pericardial Fluid	Positive culture findings in any sterile body fluid	N/A	
Peritoneal Fluid	Positive culture findings in any sterile body fluid	N/A	

(table continues on page 1652)

Monograph Title	Critical Finding (Conventional Units)	Conversion Factor	Critical Finding (SI)
Phosphorus, Blood	<i>Adults:</i> less than 1 mg/dL; greater than 8.9 mg/dL; <i>children:</i> less than 1.3 mg/dL; greater than 8.9 mg/dL	SI = CU × 0.323	<i>Adults:</i> less than 0.3 mmol/L; greater than 2.9 mmol/L; <i>children:</i> less than 0.4 mmol/L; greater than 2.9 mmol/L
Pleural Fluid	Positive culture findings in any sterile body fluid	N/A	
Potassium, Blood	<i>Adults & children:</i> less than 2.5 mEq/L or mmol/L; greater than 6.2 mEq/L or mmol/L; <i>newborns:</i> less than 2.8 mEq/L or mmol/L; greater than 7.6 mEq/L or mmol/L	SI = CU × 1	<i>Adults & children:</i> less than 2.5 mmol/L; greater than 6.2 mmol/L; <i>newborns:</i> less than 2.8 mmol/L; greater than 7.6 mmol/L
Prothrombin Time and International Normalized Ratio	PT greater than 27 sec; INR greater than 5	N/A	
Pseudocholinesterase and Dibucaine Number	A positive result indicates that the patient is at risk for prolonged or unrecoverable apnea related to the inability to metabolize succinylcholine	N/A	
Rubella Antibodies	A nonimmune status in pregnant patients may present significant health consequences for the developing fetus if the mother is exposed to an infected individual	N/A	
Sodium, Blood	Less than 120 mEq/L or mmol/L; greater than 160 mEq/L or mmol/L	SI = CU × 1	Less than 120 mmol/L; greater than 160 mmol/L
Synovial Fluid	Positive culture findings in any sterile body fluid	N/A	

Monograph Title	Critical Finding (Conventional Units)	Conversion Factor	Critical Finding (SI)
Thyroxine, Total	Less than 2 mcg/dL; greater than 20 mcg/dL	SI = CU × 17.1	Less than 34.2 nmol/L; greater than 342 nmol/L
Tuberculin Skin Tests	Positive results	N/A	
Urea Nitrogen, Blood	<i>Adults</i> : greater than 100 mg/dL (nondialysis patients); <i>children</i> : greater than 55 mg/dL (nondialysis patients)	SI = CU × 0.357	<i>Adults</i> : greater than 35.7 mmol/L (nondialysis patients); <i>children</i> : greater than 19.6 mmol/L (nondialysis patients)
Uric Acid, Blood	<i>Adults</i> : greater than 13 mg/dL; <i>children</i> : greater than 12 mg/dL	SI = CU × 0.059	<i>Adults</i> : greater than 0.8 mmol/L; <i>children</i> : greater than 0.7 mmol/L
Urinalysis	Presence of uric acid, cystine, leucine, or tyrosine crystals; the combination of grossly elevated urine glucose and ketones is also considered significant	N/A	
Vitamins A, D, E, K	Vitamin toxicity can be as significant as problems brought about by vitamin deficiencies. The potential for toxicity is especially important to consider with respect to fat-soluble vitamins, which are not eliminated from the body as quickly as water-soluble vitamins and can accumulate in the body	N/A	

Appendix C

Diagnostic Critical Findings

Monograph Title	Critical Finding
Angiography, Abdomen	Abscess; aneurysm
Angiography, Coronary	Aneurysm; aortic dissection
Angiography, Pulmonary	Pulmonary embolism
Blood Pool Imaging	Myocardial infarction
Chest X-Ray	Foreign body; malposition of tube, line, or post-operative device (pacemaker); pneumonia; pneumoperitoneum; pneumothorax; spine fracture
Computed Tomography, Abdomen	Abscess; acute gastrointestinal (GI) bleed; aortic aneurysm; appendicitis; aortic dissection; bowel perforation; bowel obstruction; mesenteric torsion; tumor with significant mass effect; visceral injury (significant solid organ laceration)
Computed Tomography, Angiography	Brain or spinal cord ischemia; emboli; hemorrhage; leaking aortic aneurysm; occlusion; tumor with significant mass effect
Computed Tomography, Brain	Abscess; acute hemorrhage; aneurysm; infarction; infection; tumor with significant mass effect
Computed Tomography, Pelvis	Ectopic pregnancy; tumor with significant mass effect
Computed Tomography, Spine	Cord compression; fracture; tumor with significant mass effect
Computed Tomography, Spleen	Abscess; hemorrhage; laceration
Computed Tomography, Thoracic	Aortic aneurysm; aortic dissection; pneumothorax; pulmonary embolism
Ductography	Ductal carcinoma in situ (DSIS); invasive breast cancer
Echocardiography	Aneurysm; infection; obstruction; tumor with significant mass effect
Echocardiography, Transesophageal	Aneurysm; aortic dissection
Electrocardiogram	Adult: Acute changes in ST elevation may indicate acute myocardial infarction or pericarditis; asystole; heart block, second and third degree with bradycardia less than 60 beats per min; pulseless electrical activity; pulseless ventricular tachycardia; PVCs greater than three in a row, pauses greater than 3 sec, or identified blocks; unstable tachycardia; ventricular fibrillation

Monograph Title	Critical Finding
Electrocardiogram	Pediatric: Asystole; bradycardia less than 60 beats per minute; pulseless electrical activity; pulseless ventricular tachycardia; supraventricular tachycardia; ventricular fibrillation
Electroencephalography	Abscess; brain death; head injury; hemorrhage; intracranial hemorrhage
Esophagogastroduodenoscopy	Presence and location of acute GI bleed
Gastrointestinal Blood Loss Scan	Acute GI bleed
Kidney, Ureter, and Bladder Study	Bowel obstruction; ischemic bowel; visceral injury
Laparoscopy, Abdominal	Appendicitis
Laparoscopy, Gynecologic	Ectopic pregnancy; foreign body; tumor with significant mass effect
Liver and Spleen Scan	Visceral injury
Lung Perfusion Scan	Pulmonary embolism
Lung Ventilation Scan	Pulmonary embolism
Magnetic Resonance Angiography	Aortic aneurysm; aortic dissection; occlusion; tumor with significant mass effect; vertebral artery dissection
Magnetic Resonance Imaging, Abdomen	Acute GI bleed; aortic aneurysm; infection; tumor with significant mass effect
Magnetic Resonance Imaging, Brain	Abscess; cerebral aneurysm; cerebral infarct; hydrocephalus; skull fracture or contusion; tumor with significant mass effect
Magnetic Resonance Imaging, Chest	Aortic aneurysm; aortic dissection; tumor with significant mass effect
Magnetic Resonance Imaging, Venography	Cerebral embolus; occlusion; pulmonary embolus; tumor with significant mass effect
Plethysmography	Deep vein thrombosis
Positron Emission Tomography, Brain	Aneurysm; cerebrovascular accident; tumor with significant mass effect
Ultrasound, Abdomen	Aneurysm 4 cm or greater
Ultrasound, Biophysical Profile, Obstetric	Abruption placentae; adnexal torsion; biophysical profile score between 0 and 2 is abnormal and indicates the need for assessment and immediate delivery; ectopic pregnancy; fetal death; placenta previa
Ultrasound, Pelvis (Gynecologic, Nonobstetric)	Abscess; adnexal torsion; appendicitis; infection; tumor with significant mass effect
Ultrasound, Scrotal	Testicular torsion
Ultrasound, Venous Doppler, Extremity Studies	Deep vein thrombosis
Upper Gastrointestinal and Small Bowel Series	Foreign body; perforated bowel; tumor with significant mass effect
Venography, Lower Extremity Studies	Deep vein thrombosis; pulmonary embolism

1,5-Anhydroglucitol, and diabetes, 855
 11-Dehydrothromboxane B2, and platelet response to aspirin, 1139-1140.

Abdomen

angiogram/arteriogram of, 74-79

computed tomography of, 532-537

FDG-PET scan of, 1262

gastrointestinal blood loss scan and, 844

KUB study and, 1008-1009

laparoscopy of, 1023-1026

liver and spleen scan of, 1040-1044

lymph node sonography of, 1509-1511

MRI of, 1082-1087

pelvic sonography of, 1514-1518

ultrasound of, 1478-1480

Abdominal abscess, CT of, 534

Abdominal malignancy, peritoneal fluid analysis in, 1237

Abdominal mass

KUB study of, 1008-1009

laparoscopy for, 1023-1024

liver and spleen scan of, 1041

MRI of, 1084

Abdominal pain

acetaminophen intoxication and, 71

gastrointestinal blood loss scan in, 845

KUB study in, 1008-1009

laparoscopy in, 1023-1024

Meckel's diverticulum scan in, 1130

nursing implications and procedures, 780, 896, 1020

parasites and, 1205

urine porphyrins in. *See* DavisPlus

Abdominal trauma/injury

amylase levels in, 64

CT of, 534

laparoscopy in, 1023

liver/spleen scan after, 1041

peritoneal fluid analysis in, 1237

ultrasonography after, 1516

Abdominal wall defect, fetal, AFP levels in, 792

Abetalipoprotein deficiency, fecal fat in, 784

Abetalipoproteinemia

apolipoprotein A in, 170

HDLC and LDLC levels in, 425

triglyceride levels in, 1454

vitamin A levels in, 1605

vitamin E and, 1602

ABGs (arterial blood gases), 293-307

ABI (ankle-brachial index), 730-731

ABO blood group, 308-315

ABO hemolytic reaction, transfusion related. *See* DavisPlus

Abortion

AFP levels in, 792

progesterone testing in, 1300

threatened. *See* Threatened abortion

ABR (auditory brainstem response), 769, 770

Abrasion, corneal, slit-lamp biomicroscopy of, 1394

Abruptio placentae

fibrin degradation products in, 803

ultrasonography in, 1494

Abscess

abdominal angiography of, 74-79

abdominal CT of, 534

abdominal ultrasonography of, 1479

brain CT of, 551

brain MRI for, 1089

breast ultrasonography of, 1501

bronchoscopy for, 330

cancer antigen levels in, 360

carotid angiography of, 87

CT angiography of, 539

EEG in, 736-737

gallium scan in, 827

liver and spleen scan for, 1041

liver/biliary tract CT of, 545

lymph node and retroperitoneal

ultrasonography for, 1510

mammography for, 1127

pancreatic CT of, 566

pelvic CT of, 571

pituitary CT of, 576

pituitary MRI for, 1118

proctosigmoidoscopy for, 1296

prostatic ultrasonography for, 1519

renal angiography in, 105

renal CT for, 580-581

renogram for, 1360

scrotal ultrasound for, 1522

splenic CT of, 590

splenic ultrasound for, 1525

BD Vacutainer® Venous Blood Collection

Tube Guide

Tubes with BD Hemogard™ Closure	Tubes with Conventional Stopper	Additive	Inversions at Blood Collection*	Laboratory Use
Gold 	Red/Gray 	<ul style="list-style-type: none"> Clot activator and gel for serum separation 	5	For serum determinations in chemistry. May be used for routine blood donor screening and diagnostic testing of serum for infectious disease.** Tube inversions ensure mixing of clot activator with blood. Blood clotting time: 30 minutes.
Light Green 	Green/Gray 	<ul style="list-style-type: none"> Lithium heparin and gel for plasma separation 	8	For plasma determinations in chemistry. Tube inversions ensure mixing of lot activator with blood. Blood clotting time: 60 minutes.
Red 		<ul style="list-style-type: none"> None (glass) Clot activator (plastic) 	0 5	For serum determinations in chemistry. May be used for routine blood donor screening and diagnostic testing of serum for infectious disease.** Tube inversions ensure mixing of clot activator with blood. Blood clotting time: 60 minutes.
Orange 		<ul style="list-style-type: none"> Thrombin-based clot activator with gel for serum separation 	5-6	For stat serum determinations in chemistry. Tube inversions ensure mixing of clot activator with blood. Blood clotting time: 5 minutes.
Orange 		<ul style="list-style-type: none"> Thrombin-based clot activator 	8	For stat serum determinations in chemistry. Tube inversions ensure mixing of clot activator with blood. Blood clotting time: 5 minutes.
Royal Blue 		<ul style="list-style-type: none"> Clot activator (plastic serum) K₂EDTA (plastic) 	8 8	For trace-element, toxicology, and nutritional chemistry determinations. Special stopper formulation provides low levels of trace elements (see package insert). Tube inversions ensure mixing of either clot activator or anticoagulant (EDTA) with blood.
Green 	Green 	<ul style="list-style-type: none"> Sodium heparin Lithium heparin 	8 8	For plasma determinations in chemistry. Tube inversions ensure mixing of anticoagulant (heparin) with blood to prevent clotting.
Gray 	Gray 	<ul style="list-style-type: none"> Potassium oxalate/sodium fluoride Sodium fluoride/Na₂ EDTA Sodium fluoride (serum tube) 	8 8 8	For glucose determinations. Oxalate and EDTA anticoagulants will give plasma samples. Sodium fluoride is the antiglycolytic agent. Tube inversions ensure proper mixing of additive and blood.
Tan 		<ul style="list-style-type: none"> K₂EDTA (plastic) 	8	For lead determinations. This tube is certified to contain less than .01 µg/mL (ppm) lead. Tube inversions prevent clotting.

Tubes with BD Hemogard™ Closure	Tubes with Conventional Stopper	Additive	Inversions at Blood Collection*	Laboratory Use
	Yellow 	<ul style="list-style-type: none"> Sodium polyanethol sulfonate (SPS) Acid citrate dextrose additives (ACD): Solution A - 22.0 g/L trisodium citrate, 8.0 g/L citric acid, 24.5 g/L dextrose Solution B - 13.2 g/L trisodium citrate, 4.8 g/L citric acid, 14.7 g/L dextrose 	8 8 8	SPS for blood culture specimen collections in microbiology. ACD for use in blood bank studies, HLA phenotyping, and DNA and paternity testing. Tube inversions ensure mixing of anticoagulant with blood to prevent clotting.
Lavender 	Lavender 	<ul style="list-style-type: none"> Liquid K₂EDTA (glass) Spray-coated K₂EDTA (plastic) 	8 8	K ₂ EDTA and K ₃ EDTA for whole blood hematology determinations. K ₂ EDTA may be used for routine immunohematology testing and blood donor screening.*** Tube inversions ensure mixing of anticoagulant (EDTA) with blood to prevent clotting.
White 		<ul style="list-style-type: none"> K₂EDTA and gel for plasma separation 	8	For use in molecular diagnostic test methods (such as, but not limited to, polymerase chain reaction [PCR] and/or branched DNA [bDNA] amplification techniques). Tube inversions ensure mixing of anticoagulant (EDTA) with blood to prevent clotting.
Pink 	Pink 	<ul style="list-style-type: none"> Spray-coated K₂EDTA (plastic) 	8	For whole blood hematology determinations. May be used for routine immunohematology testing and blood donor screening.*** Designed with special cross-match label for patient information required by the AABB. Tube inversions prevent clotting.
Light Blue 	Light Blue 	<ul style="list-style-type: none"> Buffered sodium citrate 0.105 M (≈3.2%) glass 0.109 M (≈3.2%) plastic Citrate, theophylline, adenosine, dipyridamole (CTAD) 	3-4 3-4	For coagulation determinations. CTAD for platelet function assays and routine coagulation determination. Tube inversions ensure mixing of anticoagulant (citrate) to prevent clotting.
Clear 				
Clear 	Red/Lite Gray NEW 	<ul style="list-style-type: none"> None (plastic) 	0	For use as a discard tube or secondary specimen collection tube.

* Invert gently, do not shake

** The performance characteristics of these tubes have not been established for infectious disease testing in general; therefore, users must validate the use of these tubes for their specific assay-instrument/reagent system combinations and specimen storage conditions.

*** The performance characteristics of these tubes have not been established for immunohematology testing in general; therefore, users must validate the use of these tubes for their specific assay-instrument/reagent system combinations and specimen storage conditions.
