As new scientific information becomes available through basic and clinical research, recommended treatments and drug therapies undergo changes. The authors and publisher have done everything possible to make this book accurate, up to date, and in accord with accepted standards at the time of publication. The authors, editors, and publisher are not responsible for errors or omissions or for consequences from application of the book, and make no warranty, expressed or implied, in regard to the contents of the book. Any practice described in this book should be applied by the reader in accordance with professional standards of care used in regard to the unique circumstances that may apply in each situation. The reader is advised always to check product information (package inserts) for changes and new information regarding dose and contraindications before administering any drug. Caution is especially urged when using new or infrequently ordered drugs.

Dedication

Inspiration springs from Passion. . . . Passion is born from unconstrained love, commitment, and a vision no one else can own.

Lynda—my best friend and extraordinarily gifted nurse—thank you, I could not have done this without your love, strong support, and belief in me. My gratitude to Mom, Dad, Adele, Gram . . . all my family and friends, for I am truly blessed by your humor and faith. A huge hug for my daughters, Sarah and Margaret—I love you very much. To my puppies, Maggie, Taylor, and Emma, for their endless and unconditional love. Many thanks to my friend and wonderful coauthor Mickey; to all the folks at F.A. Davis, especially Rob and Victoria for their guidance, support, and great ideas. And, very special thanks to Lisa Houck, publisher, for her friendship, excellent direction, and unwavering encouragement.

Anne M. Van Leeuwen, MA, BS, MT (ASCP)

Medical Laboratory Scientist & Independent Author
Greater Seattle Area, Washington

An eternity of searching would never have provided me with a man more loving and supportive than my husband, Eric. He is the sunshine in my soul, and I will be forever grateful for the blessing of his presence in my life. I am grateful to my five children, Eric, Anni, Phillip, Mari, and Melissa, for the privilege of being their mom; always remember that you are limited only by your imagination and willingness to try. To Anne, thanks so much for the opportunity to spread my wings, for your patience and guidance, and thanks to Lynda for the miracle of finding me. To all of those at F.A. Davis—Rob, Victoria, and Lisa—you are the best. Lastly, to my beloved parents, thanks with hugs and kisses.

Mickey L. Bladh, RN, MSN

Coordinator, Nursing Education
PIH Health Hospital
Whittier, California

We are so grateful to all the people who have helped us make this book possible. We thank our readers for allowing us this important opportunity to touch their lives. We are also thankful for our association with the F.A. Davis Company. We value and appreciate the efforts of all the people associated with F.A. Davis because without their hard work this publication could not succeed. We recognize all the wonderful people in leadership, the editors, freelance consultants, designers, IT gurus, and digital applications developers, as well as those in sales & marketing, distribution, and finance. We have a deep appreciation for the Davis Educational Consultants. They are tasked with being our voice. Their exceptional ability to communicate is what actually brings our book to the market. We would like to give special

acknowledgement to the outstanding publishing professionals who were our core support team throughout the development of this edition:

About This Book

This book is a reference for nurses, nursing students, and other health-care professionals. It is useful as a clinical tool as well as a supportive text to supplement clinical courses. It guides the nurse in planning what needs to be assessed, monitored, treated, and taught regarding pretest requirements, intratest procedures, and post-test care. It can be used by nursing students at all levels as a textbook in theory classes, integrating laboratory and diagnostic data as one aspect of nursing care; by practicing nurses to update information; and in clinical settings as a quick reference. Designed for use in academic and clinical settings, *Davis's Comprehensive Handbook of Laboratory and Diagnostic Tests—With Nursing Implications* provides a comprehensive reference that allows easy access to information about laboratory and diagnostic tests and procedures.

WHAT'S NEW IN THE 6TH EDITION?

Two new monographs:

- Genetic Testing
- Bioterrorism and Public Health Safety Concerns: Testing for Toxins and Infectious Agents

New or updated information for more than 50 different tests including further discussion of:

- Molecular testing and companion diagnostics
- Pediatric and geriatric considerations
- Specific contraindications and corresponding rationales
- Specific nursing problems, associated patient signs and symptoms, and potential nursing interactions
- Specific complications with corresponding rationales and potential interventions
- Patient education, including references to Websites for information related to specific health conditions or disease management guidelines
- Expected patient outcomes expressed in terms of understanding, ability, and response. The expected patient outcomes are expressed in statements that reflect the patient's understanding of their medical situation and what it will take to achieve the most positive outcome possible; their demonstrated ability to apply instructions, explanations, and education toward a goal; and their response to various aspects of Safe and Effective Nursing Care used in their situation
- Material regarding genetic markers for Alzheimer's disease; tests used to diagnose gluten-sensitive enteropathies; immunosuppressant therapies used for organ transplant patients; genetic testing for drug resistance; description of the arterial brachial index; tests used to evaluate intermediate glycemic control; the use of pharmacogenetics to help explain why some patients don't respond as expected to their medications; and the use of home test kits added in previous editions

Evidence-based practice is reflected throughout in:

- Suggestions for patient teaching that reflect changes in standards of care, particularly with respect to current guidelines for cancer screening
- The most current Centers for Disease Control and Prevention (CDC) guidelines for communicable diseases such as syphilis, tuberculosis, and HIV

- The most current guidelines for the prevention of cardiovascular disease (CVD) developed by the American College of Cardiology (ACA) and the American Heart Association (AHA) in conjunction with members of the National Heart, Lung, and Blood Institute's (NHLBI) ATP IV Expert Panel

Critical Findings sections now include:

- A sample statement that walks the nurse through the process for timely notification and documentation of critical values
- Conventional and SI units
- Commonly reported pediatric and neonatal values

The Reference Value heading in the laboratory monographs is now called Normal Findings to (a) use terminology that is easier to recognize and interpret and (b) use consistent terminology in laboratory and diagnostic monographs.

We've included related information within the following monographs for this edition:

- Nasal cytology in Allergen-Specific Immunoglobulin E
- Digital subtraction in all the angiography monographs
- Post void residual in Cystometry
- Xenon enhanced CT in Computed Tomography, Brain
- Magnetic resonance cholangiopancreatography in Magnetic Resonance Imaging, Abdomen
- Bladder scan in Ultrasound, Bladder
- Digital rectal examination (DRE) in Ultrasound, Prostate

Some monographs have been combined to consolidate similar tests, and a few less frequently used tests have been condensed into a mini-monograph format that highlights abbreviated test-specific facts, with the full monographs for those tests now resident on the DavisPlus Web site (<http://davisplus.fadavis.com>).

The *System Tables* at the back of the book now indicate the individual studies that contain information regarding genetic testing so the information, also in the index, can be located quickly.

New: The Intersection of Nursing Care and Lab/Dx Testing

We hear every day from students and instructors that they want a laboratory and diagnostic test reference that will help them “connect-the-dots”—that will show them how to integrate laboratory and diagnostic test results into safe, compassionate, comprehensive, and effective nursing care. So we have revised the 6th edition of the Handbook to be not only the comprehensive reference it was originally designed to be, but it now also presents carefully selected studies that have been enhanced to reflect aspects of Safe and Effective Nursing Care. The enhanced studies allow the reader to drill down further into the nursing implications. More than 80 studies have been expanded and examples include:

- Bilirubin
- Blood Gases
- Blood Groups and Antibodies
- Cerebrospinal Fluid Analysis
- Chlamydia Group Antibody
- Chloride, Sweat
- Complete Blood Count, Hemoglobin; Platelet Count; and WBC Count

- D-Dimer
- Glucose
- Glucose Tolerance Tests
- Newborn Screening
- Prostate Specific Antigen
- Prothrombin Time and INR
- Rheumatoid Factor
- Thyroid Stimulating Hormone
- Tuberculosis Testing

WHAT'S NEW ONLINE?

Davisplus

The following additional information is available at the DavisPlus web site (<http://davisplus.fadavis.com>):

- Case studies in both instructor and student versions formatted to help the novice learn how to clinically reason by using the nursing process to problem solve. Cases are purposefully designed to promote discussion of situations that may occur in the clinical setting. Situations may be medical, ethical, family-related, patient-related, nurse-related, or any combination.
- Common potential nursing diagnoses associated with laboratory and diagnostic testing.
- Age-specific nursing care guidelines with suggested approaches to persons at various developmental stages to assist the provider in facilitating cooperation and understanding.
- Transfusion reactions, their signs and symptoms, associated laboratory findings, and potential nursing interventions.
- Introduction to CLIA (Clinical Laboratory Improvement Amendments) with an explanation of the different levels of testing complexity.
- Herbs and nutraceuticals associated with adverse clinical reactions or drug interactions related to the affected body system.
- Standard precautions.
- Interactive drag-and-drop, quiz-show, flash card, and multiple-choice exercises.
- A printable file of critical findings for laboratory and diagnostic tests.

Instructor Guide and Student Guide

- Organized by nursing curriculum, presentations, and case studies with emphasis on laboratory and diagnostic test-related information and nursing implications have been developed for selected conditions and body systems, including sensory, obstetric, and nutrition coverage.
- Open-ended and NCLEX-type multiple-choice questions as well as suggested critical-thinking activities are provided.
- Updated with broadened age-related categories designed to enhance clinical communication. Each case study includes at least one test that appears in the 6e Handbook as an enhanced monograph. Information in the enhanced monograph can be referenced in the Handbook for the material that contains detailed nursing problems, complications, patient education, and expected patient outcomes for additional Safe and Effective Nursing Care teaching moments.
- PowerPoint presentation of laboratory and diagnostic pretest, intratest, and post-test concepts integrated with nursing process.

Monograph Library

- A searchable library of mini-monographs for all the active tests included in the text. The mini-monograph gives each test's full name, synonyms and acronyms, specimen type (laboratory tests) or area of application (diagnostic tests), reference ranges or contrast, and results.
- An archive of full monographs of retired tests that are referenced by mini-monographs in the text.

WHAT WE KEPT FROM PREVIOUS EDITIONS

System Tables

Alphabetical listings of laboratory and diagnostic tests organized by related body systems. The tables have been revised to quickly identify individual tests in each table that contain information regarding genetic testing.

Alphabetical Order

The tests and procedures are presented in this book in alphabetical order by their complete name, allowing the user to locate information quickly without having to first place tests in a specific category or body system. Wherever possible, information within the Indications, Potential Diagnosis, and Interfering Factors (drug lists) sections also has been organized alphabetically.

Consistent Format

The following information is provided for each laboratory and diagnostic tests:

- Each monograph is titled by the *test name* and given in its commonly used designation.
- *Synonyms and Acronyms* for each test are listed where appropriate.
- The *Common Use* section includes a brief description of the purpose for the study.
- The *Specimen* section includes the type of specimen usually collected and, where appropriate, the type of collection tube or container commonly recommended. The amount of specimen collected for blood studies reflects the amount of serum, plasma, or whole blood required to perform the test and thus provides a way to project the total number of specimen containers required because patients usually have multiple laboratory tests requested for a single draw. Specimen requirements vary by laboratory. The amount of specimen collected is usually more than what is minimally required so that additional specimen is available, if needed, for repeat testing (quality-control failure, dilutions, or confirmation of unexpected results). In the case of diagnostic tests, the *type* of procedure (e.g., nuclear medicine, x-ray) is given.
- *Normal Findings* for each monograph include age-specific, gender-specific, and ethnicity-specific variations, when indicated. It is important to consider the normal variation of laboratory values over the life span and across cultures; sometimes what might be considered an abnormal value in one circumstance is actually what is expected in another. Normal findings for laboratory tests are given in conventional and standard international (SI) units. The factor used to convert conventional to SI units is also given. Because laboratory values can vary by method, each laboratory reference range is listed along with the associated methodology.
- The *Description* section includes the study's purpose and insight into how and why the test results can affect health. Some test descriptions also provide

insight into how test results influence the development of national health guidelines.

- A separate *Contraindications* section has been created to differentiate circumstances that might put the patient at risk if the procedure is performed from interfering factors that may indirectly affect patient care by adversely affecting the results of the study.
- *Indications* are a list of what the test is used for in terms of assessment, evaluation, monitoring, screening, identifying, or assisting in the diagnosis of a clinical condition.
- The *Potential Diagnosis* section presents a list of conditions in which values may be increased or decreased and, in some cases, an explanation of variations that may be encountered.
- *Critical Findings* that may be life threatening or for which particular concern may be indicated are given in conventional and SI units, along with age span considerations where applicable. This section also includes signs and symptoms associated with a critical value as well as possible nursing interventions and the nurse's role in communication of critical findings to the appropriate health-care provider.
- *Interfering Factors* are substances or circumstances that may influence the results of the test, rendering the results invalid or unreliable. Knowledge of interfering factors is an important aspect of quality assurance and includes pharmaceuticals, foods, natural and additive therapies, timing of test in relation to other tests or procedures, collection site, handling of specimen, and underlying patient conditions.
- The *Pretest* section addresses the need to:
 - Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
 - Provide an explanation to the patient, in the simplest terms possible, of the purpose of the study.
 - Obtain pertinent clinical, laboratory, dietary, and therapeutic history of the patient, especially as it pertains to comparison of previous test results, preparation for the test, and identification of potentially interfering factors.
 - Explain the requirements and restrictions related to the procedure as well as what to expect; provide the education necessary for the patient to be properly informed.
 - Anticipate and allay patient and family concerns or anxieties with consideration of social and cultural issues during interactions.
 - Provide for patient safety.

Some monographs have an additional section for Nursing Problems at the beginning of the pretest section. The enhanced information presents problems the nurse might encounter relative to the study topic (e.g., glucose), signs and symptoms associated with abnormal study findings, and possible interventions. The additional information provides the reader with the opportunity to “drill” further down into the nursing implications. It is provided with the thought that incorporating laboratory and diagnostic data, on a day-to-day basis, by using the nursing process can be taught and reinforced using simple examples.

- The *Intratest* section can be used in a quality-control assessment or as a guide to the nurse who may be called on to participate in specimen collection or perform preparatory procedures. It provides:
 - Specific directions for specimen collection and test performance

- Important information such as patient sensation and expected duration of the procedure
- Precautions to be taken by the nurse and patient

Some monographs have an additional section for study specific complications and rationales in the Intratest section. The additional information is another opportunity to “drill” further down into the nursing implications. It is provided as a reminder to anticipate the potential for procedural complications and be prepared to identify them across the age continuum.

- The *Post-Test* section provides guidelines regarding:
 - Specific monitoring and therapeutic measures that should be performed after the procedure (e.g., maintaining bedrest, obtaining vital signs to compare with baseline values, signs and symptoms of complications)
 - Specific instructions for the patient and family, such as when to resume usual diet, medications, and activity
 - General nutritional guidelines related to excess or deficit as well as common food sources for dietary replacement
 - Indications for interventions from public health representatives or for special counseling related to test outcomes
 - Indications for follow-up testing that may be required within specific time frames
 - An alphabetical listing of related laboratory and/or diagnostic tests that is intended to provoke a deeper and broader investigation of multiple pieces of information; the tests provide data that, when combined, can form a more complete picture of health or illness
 - Reference to the specific body system tables of related laboratory and diagnostic tests that might bear on a patient’s situation

Some monographs have an additional section for specific patient education and expected patient outcomes in the post-test section. The additional information is another opportunity to “drill” further down into the nursing implications. It is provided as a reminder of the nurse’s role as educator and advocate.

Color and Icons

Design is used to facilitate locating critical information at a glance. On the inside front and back covers is a full-color chart describing tube tops used for various blood tests and their recommended order of draw.

Nursing Process

Within each phase of the testing procedure, we describe the nurse’s roles and responsibilities as defined by the nursing process.

Appendices

These include:

- A summary of guidelines for patient preparation with specimen collection procedures and materials which has been revised to reflect considerations for special patient populations.
- A listing of critical findings for laboratory studies.
- A listing of critical findings for diagnostic studies.

Index

Completely updated to reflect the addition of new tests, conditions, and other key words.

Assumptions

- The authors recognize that preferences for the use of specific medical terminology may vary by institution. Much of the terminology used in this Handbook is sourced from Taber's Cyclopedic Medical Dictionary.
- The definition, implementation, and interpretation of national guidelines for the treatment of various medical conditions changes as new information and new technology emerge. The publication of updated information may at times be contentious among the professional institutions that offer either support or dissent for the proposed changes. This can cause confusion when a patient asks questions about how their condition will be identified and managed. The authors believe that the most important discussion about health care occurs between the patient and their health-care provider(s). While the individual studies may point out various screening tests used to identify a disease, the authors often refer the reader to Websites maintained by nationally recognized authorities on a specific topic that reflect the most current information and recommendations for screening, diagnosis, and treatment.
- Most institutions have established policies, protocols, and interdisciplinary teams that provide for efficient and effective patient care within the appropriate scope of practice. While it is not our intention that the actual duties a nurse may perform be misunderstood by way of misinterpreted inferences in writing style, the information prepared by the authors considers that specific limitations are understood by the licensed professionals and other team members involved in patient care activities and that the desired outcomes are achieved by order of the appropriate health-care provider.

Laboratory and diagnostic testing. The words themselves often conjure up cold and impersonal images of needles, specimens lined up in collection containers, and high-tech electronic equipment. But they do not stand alone. They are tied to, bound with, and tell of health or disease in the blood and tissue of a person. Laboratory and diagnostic studies augment the health-care provider's assessment of the quality of an individual's physical being. Test results guide the plans and interventions geared toward strengthening life's quality and endurance. Beyond the pounding noise of the MRI, the cold steel of the x-ray table, the sting of the needle, the invasive collection of fluids and tissue, and the probing and inspection is the gathering of evidence that supports the health-care provider's ability to discern the course of a disease and the progression of its treatment. Laboratory and diagnostic data must be viewed with thought and compassion, however, as well as with microscopes and machines. We must remember that behind the specimen and test result is the person from whom it came, a person who is someone's son, daughter, mother, father, husband, wife, or friend.

This book is written to help health-care providers in their understanding and interpretation of laboratory and diagnostic procedures and their outcomes. Just as important, it is dedicated to all health-care professionals who experience the wonders in the science of laboratory and diagnostic testing, performed and interpreted in a caring and efficient manner.

The authors have continued to enhance four areas in this new edition: pathophysiology that affects test results, patient safety, patient education, and integration of related laboratory and diagnostic testing.

First, the Potential Diagnosis section includes an explanation of increased or decreased values, as many of you requested. We have added age-specific reference values for the neonatal, pediatric, and geriatric populations at the request of some of our readers. It should be mentioned that standardized information for the complexity of a geriatric population is difficult to document. Values may be increased or decreased in older adults due to the sole or combined effects of malnutrition, alcohol use, medications, and the presence of multiple chronic or acute diseases with or without muted symptoms.

Second, the authors appreciate that nurses are the strongest patient advocates with a huge responsibility to protect the safety of their patients, and we have observed student nurses in clinical settings being interviewed by facility accreditation inspectors, so we have updated safety reminders, particularly with respect to positive patient identification, communication of critical information, proper timing of diagnostic procedures, rescheduling of specimen collection for therapeutic drug monitoring, use of evidence-based practices for prevention of surgical site infections, information regarding the move to track or limit exposure to radiation from CT studies for adults, and the Image Gently campaign for pediatric patients who undergo diagnostic studies that utilize radiation. The pretest section reminds the nurse to positively identify the patient before providing care, treatment, or services. The pretest section also addresses hand-off communication of critical information.

The third area of emphasis coaches the student to focus on patient education and prepares the nurse to anticipate and respond to a patient's questions or concerns: describing the purpose of the procedure, addressing concerns

about pain, understanding the implications of the test results, and describing post-procedural care. Various related Websites for patient education are included throughout the book.

And fourth, laboratory and diagnostic tests do not stand on their own—all the pieces fit together to form a picture. The section at the end of each monograph integrates both laboratory and diagnostic tests, providing a more complete picture of the studies that may be encountered in a patient's health-care experience. The authors thought it useful for a nurse to know what other tests might be ordered together—and all the related tests are listed alphabetically for ease of use.

Laboratory and diagnostic studies are essential components of a complete patient assessment. Examined in conjunction with an individual's history and physical examination, laboratory studies and diagnostic data provide clues about health status. Nurses are increasingly expected to integrate an understanding of laboratory and diagnostic procedures and expected outcomes in assessment, planning, implementation, and evaluation of nursing care. The data help develop and support nursing diagnoses, interventions, and outcomes.

Nurses may interface with laboratory and diagnostic testing on several levels, including:

- Interacting with patients and families of patients undergoing diagnostic tests or procedures, and providing pretest, intratest, and posttest information and support
- Maintaining quality control to prevent or eliminate problems that may interfere with the accuracy and reliability of test results
- Providing education and emotional support at the point of care
- Ensuring completion of testing in a timely and accurate manner
- Collaborating with other health-care professionals in interpreting findings as they relate to planning and implementing total patient care
- Communicating significant alterations in test outcomes to appropriate health-care team members
- Coordinating interdisciplinary efforts

Whether the nurse's role at each level is direct or indirect, the underlying responsibility to the patient, family, and community remains the same.

The authors hope that the changes and additions made to the book and its Web-based ancillaries will reward users with an expanded understanding of and appreciation for the place laboratory and diagnostic testing holds in the provision of high-quality nursing care and will make it easy for instructors to integrate this important content in their curricula. The authors would like to thank all the users of the previous editions for helping us identify what they like about this book as well as what might improve its value to them. We want to continue this dialogue. As writers, it is our desire to capture the interest of our readers, to provide essential information, and to continue to improve the presentation of the material in the book and ancillary products. We encourage our readers to provide feedback to the Website and to the publisher's sales professionals. Your feedback helps us modify the material—to change with your changing needs.

Bibliography

Acetylcholine Receptor Antibody

SYNONYM/ACRONYM: AChR (AChR-binding antibody, AChR-blocking antibody, and AChR-modulating antibody).

COMMON USE: To assist in confirming the diagnosis of myasthenia gravis (MG).

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Radioimmunoassay) AChR-binding antibody: Less than 0.4 nmol/L, AChR-blocking antibody: Less than 25% blocking, and AChR-modulating antibody: Less than 30% modulating.

DESCRIPTION: Normally when impulses travel down a nerve, the nerve ending releases a neurotransmitter called acetylcholine (ACh), which binds to receptor sites in the neuromuscular junction, eventually resulting in muscle contraction. Once the neuromuscular junction is polarized, ACh is rapidly metabolized by the enzyme acetylcholinesterase. When present, AChR-binding antibodies can activate complement and create a complex of ACh, AChR-binding antibodies, and complement. This complex renders ACh unavailable for muscle receptor sites. If AChR—binding antibodies are not detected, and myasthenia gravis (MG) is strongly suspected, AChR-blocking and AChR-modulating antibodies may be ordered. AChR-blocking antibodies impair or prevent ACh from attaching to receptor sites on the muscle membrane, resulting in poor muscle contraction. AChR-modulating antibodies destroy AChR sites, interfering with neuromuscular transmission. The lack of ACh bound to muscle receptor sites results in muscle weakness. Antibodies to AChR sites are present in 90% of patients with generalized MG and in 55% to 70% of patients who either have ocular forms of MG or are in remission.

Approximately 10% to 15% of people with confirmed MG do not demonstrate detectable levels of AChR-binding, -blocking, or -modulating antibodies. MG is an acquired autoimmune disorder that can occur at any age. Its exact cause is unknown, and it seems to strike women between ages 20 and 40 years; men appear to be affected later in life than women. It can affect any voluntary muscle, but muscles that control eye, eyelid, facial movement, and swallowing are most frequently affected. Antibodies may not be detected in the first 6 to 12 months after the first appearance of symptoms. MG is a common complication associated with thymoma. The relationship between the thymus gland and MG is not completely understood. It is believed that miscommunication in the thymus gland directed at developing immune cells may trigger the development of autoantibodies responsible for MG. Remission after thymectomy is associated with a progressive decrease in antibody level. Other markers used in the study of MG include striational muscle antibodies, thyroglobulin, HLA-B8, and HLA-DR3. These antibodies are often undetectable in the early stages of MG.

This procedure is contraindicated for

-  Patients who have received radioactive scans or radiation within 1 wk of the test. Results may be invalidated when radioimmunoassay is the test method. Appropriate timing when scheduling multiple studies should be taken into consideration.

INDICATIONS

- Confirm the presence but not the severity of MG
- Detect subclinical MG in the presence of thymoma
- Monitor the effectiveness of immunosuppressive therapy for MG
- Monitor the remission stage of MG

POTENTIAL DIAGNOSIS

Increased in

- Autoimmune liver disease
- Generalized MG (*Defective transmission of nerve impulses to muscles evidenced by muscle weakness. It occurs when normal communication between the nerve and muscle is interrupted at the neuromuscular junction. It is believed that miscommunication in the thymus gland directed at developing immune cells may trigger the development of autoantibodies responsible for MG.*)
- Lambert-Eaton myasthenic syndrome
- Primary lung cancer
- Thymoma associated with MG (*Defective transmission of nerve impulses to muscles evidenced by muscle weakness. It occurs when normal communication between the nerve and muscle is interrupted at the neuromuscular junction. It is believed that miscommunication*

in the thymus gland directed at developing immune cells may trigger the development of autoantibodies responsible for MG.)

Decreased in

- Postthymectomy (*The thymus gland produces the T lymphocytes responsible for cell-mediated immunity. T cells also help control B-cell development for the production of antibodies. T-cell response is directed at cells in the body that have been infected by bacteria, viruses, parasites, fungi, or protozoans. T cells also provide immune surveillance for cancerous cells. Removal of the thymus gland is strongly associated with a decrease in AChR antibody levels.*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase AChR levels include penicillamine (long-term use may cause a reversible syndrome that produces clinical, serological, and electrophysiological findings indistinguishable from MG).
- Biological false-positive results may be associated with amyotrophic lateral sclerosis, autoimmune hepatitis, Lambert-Eaton myasthenic syndrome, primary biliary cirrhosis, and encephalomyeloneuropathies associated with carcinoma of the lung.
- Immunosuppressive therapy is the recommended treatment for MG; prior immunosuppressive drug administration may result in negative test results.
- Recent radioactive scans or radiation within 1 wk of the test can interfere with test results when radioimmunoassay is the test method.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Urination (<i>Related to neurogenic bladder; spastic bladder; associated with disease process</i>)	Urinary retention; urinary frequency; urinary urgency; pain and abdominal distention; urinary dribbling	Assess amount of fluid intake as it may be necessary to limit fluids to control incontinence; assess risk of urinary tract infection with limiting oral intake; begin bladder training program; teach catheterization techniques to family and patient self-catheterization
Self-care (<i>Related to spasticity; altered level of consciousness; paresis; increasing weakness; paralysis</i>)	Difficulty fastening clothing; difficulty performing personal hygiene; inability to maintain appropriate appearance; difficulty with independent mobility; declining physical function	Reinforce self-care techniques as taught by occupational therapy; ensure the patient has adequate time to perform self-care; encourage use of assistive devices to maintain independence; assess ability to perform ADLs; provide care assistance appropriate to degree of disability while maintaining as much independence as possible
Mobility (<i>Related to weakness; tremors; spasticity</i>)	Unsteady gait; lack of coordination; difficult purposeful movement; inadequate range of motion	Assess gait; assess muscle strength; assess weakness and coordination; assess physical endurance and level of fatigue; assess ability to perform independent ADLs; assess ability for safe, independent movement; identify need for assistive device; encourage safe self-care
Pain (<i>Related to motor and sensory nerve damage associated with disease process</i>)	Self-report of pain; emotional symptoms of distress; crying; agitation; facial grimace; moaning; verbalization of pain; rocking motions; irritability; disturbed sleep; diaphoresis; altered blood pressure and heart rate; nausea; vomiting	Keep the immediate environment cool to decrease aggravating MG symptoms; use passive or active range of motion to decrease muscle tightness; administer analgesics, tranquilizers, antispasmodics, and neuropathic pain medication, as ordered

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that the test is used to identify antibodies responsible for decreased neuromuscular transmission and associated muscle weakness.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, and any prior complications with general anesthesia.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of activity challenges related to lack of neuromuscular control, anticipated loss of independence, and fear of death. It is important to note that a diagnosis of MG should be based on abnormal findings from two different diagnostic tests. These tests include AChR antibody assay, anti-MuSK antibody assay (an antibody which is produced in 40% to 70% of the remaining 15% who have MG but test negative for AChR antibody), edrophonium test (which involves injection of edrophonium or tensilon, a medication that temporarily blocks the degradation of acetylcholine, allowing normal measurable neuromuscular transmission that dissipates as the effects of the injection wear off), repetitive nerve stimulation (small pulses of electricity are repeatedly sent to specific muscles by way of electrodes to measure a decrease in response due to muscle weakening), and single-fiber electromyography (see EMG monograph for more detailed information). Discuss the implications of positive test results on the patient's lifestyle. Positive test results may lead to testing for other conditions associated with MG. Thyrotoxicosis may occur in conjunction with MG; related thyroid testing may be indicated. MG patients may also produce antibodies, such as antinuclear antibody and rheumatoid factor, not primarily associated with MG that demonstrate measurable reactivity.
- ▶ Evaluate test results in relation to future general anesthesia, especially regarding therapeutic management of MG with cholinesterase inhibitors.

Succinylcholine-sensitive patients may be unable to metabolize the anesthetic quickly, resulting in prolonged or unrecoverable apnea.

- ▶ Provide contact information, if desired, for the Myasthenia Gravis Foundation of America (www.myasthenia.org) and the Muscular Dystrophy Association (www.mdaua.org).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. If a diagnosis of MG is made, a computed tomography (CT) scan of the chest should be performed to rule out thymoma. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Discuss the implications of positive test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's health-care provider (HCP) regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach family to place self-care items within the patients reach to promote as much independence in care as possible.

▶ Teach the family and patient that assistive devices can improve quality of life and decrease injury risk.

Expected Patient Outcomes:

Knowledge

- ▶ The patient and family verbalize understanding that spasms can be decreased by adhering to recommended physical therapy.
- ▶ The patient and family describe the necessity to promote independent self-care while seeking assistance as necessary to prevent injury.

Skills

- ▶ The patient and family demonstrate the ability to perform passive and active range of motion activities.
- ▶ The patient and family demonstrate how to apply splints to hands to help control hand spasms.

Attitude

- ▶ The patient and family set personal goals regarding performance of self-care activities that are in realistic proportion to disease progression.
- ▶ The patient and family accept the physical limitations related to the disease process.

RELATED MONOGRAPHS:

- ▶ Related tests include ANA, antithyroglobulin and antithyroid peroxidase antibodies, CT chest, myoglobin, pseudocholinesterase, RF, TSH, and total T₄.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Acid Phosphatase, Prostatic

SYNONYM/ACRONYM: Prostatic acid phosphatase, *o*-phosphoric monoester phosphohydrolase, PACP PAP.

COMMON USE: To assist in staging prostate cancer and document evidence of sexual intercourse through semen identification in alleged cases of rape and sexual abuse.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

A swab with vaginal secretions may be submitted in the appropriate transfer container. Other material such as clothing may be submitted for analysis. Consult the laboratory or emergency services department for the proper specimen collection instructions and containers.

NORMAL FINDINGS: (Method: Immunochemiluminometric)

Conventional & SI Units

Less than 3.5 ng/mL

Values are elevated at birth, decrease by 6 mo, increase at approximately 10 yr through puberty, level off through adulthood, and may increase in advancing age.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

PACp is released from any damaged cell in which it is stored, so diseases of the bone, prostate, and liver that cause cellular destruction demonstrate elevated PACp levels. Conditions that result in abnormal elevations of cells that contain PACp (e.g., leukemia, thrombocytosis) or conditions that result in rapid cellular destruction

(sickle cell crisis) also reflect increased levels.

- Acute myelogenous leukemia
- After prostate surgery or biopsy
- Benign prostatic hypertrophy
- Liver disease
- Lysosomal storage diseases (Gaucher's disease and Niemann-Pick disease) *(PACp is stored in the lysosomes of blood cells, and increased levels are present in lysosomal storage diseases)*
- Metastatic bone cancer
- Paget's disease
- Prostatic cancer
- Prostatic infarct
- Prostatitis
- Sickle cell crisis
- Thrombocytosis

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Adrenal Gland Scan

SYNONYM/ACRONYM: Adrenal scintiscan.

COMMON USE: To assist in the diagnosis of Cushing's syndrome and differentiate between adrenal gland cancer and infection.

AREA OF APPLICATION: Adrenal gland.

CONTRAST: Intravenous radioactive NP-59 (iodomethyl-19-norcholesterol) or metaiodobenzylguanidine (MIBG).

DESCRIPTION: This nuclear medicine study evaluates the function of the adrenal glands. The secretory function of the adrenal glands is controlled primarily by the anterior pituitary, which produces adrenocorticotropic hormone (ACTH). ACTH stimulates the adrenal cortex to produce cortisone and secrete aldosterone. Adrenal imaging is most useful in differentiation of hyperplasia from adenoma in primary aldosteronism when computed tomography (CT) and magnetic resonance imaging (MRI) findings are equivocal. High concentrations of cholesterol (the precursor in the synthesis of adrenocorticosteroids, including aldosterone) are stored in the adrenal cortex and this allows the radionuclide, which attaches to the cholesterol, to be used in identifying pathology in the secretory function of the adrenal cortex. The uptake of the radionuclide occurs gradually over time and imaging is performed within 24 to 48 hr of radionuclide injection and continued daily for 3 to 5 days. Imaging can reveal increased uptake, unilateral or bilateral uptake, or absence of uptake in the detection of pathological processes. Following prescanning treatment with corticosteroids, suppression studies can also be done to differentiate the presence of tumor from hyperplasia of the glands.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

- ◆ Conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine; in fact, an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

INDICATIONS

- Aid in the diagnosis of Cushing's syndrome and aldosteronism
- Aid in the diagnosis of gland tissue destruction caused by infection, infarction, neoplasm, or suppression
- Aid in locating adrenergic tumors
- Determine adrenal suppressibility with prescan administration of corticosteroid to diagnose and localize adrenal adenoma, aldosteronomas, androgen excess, and low-renin hypertension
- Differentiate between asymmetric hyperplasia and asymmetry from aldosteronism with dexamethasone suppression test

POTENTIAL DIAGNOSIS**Normal findings in**

- No evidence of tumors, infection, infarction, or suppression
- Normal bilateral uptake of radionuclide and secretory function of adrenal cortex
- Normal salivary glands and urinary bladder; vague shape of the liver and spleen sometimes seen

Abnormal findings in

- Adrenal gland suppression
- Adrenal infarction
- Adrenal tumor
- Hyperplasia
- Infection
- Pheochromocytoma

CRITICAL FINDINGS: N/A**INTERFERING FACTORS****Factors that may impair clear imaging**

- Retained barium from a previous radiological procedure.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation

Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their radiation exposure level.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can visualize and assess the function of the adrenal gland, which is located near the kidney.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Perform all adrenal blood tests before doing this test.
- ▶ Record the date of last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side

effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).

- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a nuclear medicine department by a nuclear medicine technologist with support staff, and it takes approximately 1 to 2 hr each day. Inform the patient the test usually involves a prolonged scanning schedule over a period of days.
- ▶ Administer saturated solution of potassium iodide (SSKI or Lugol iodine solution) 24 hr before the study to prevent thyroid uptake of the free radioactive iodine.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, contrast medium, or emergency medications.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Injection of the contrast is an invasive procedure. Complications are rare but do include risk for: allergic reaction (**related to contrast reaction**), hematoma (**related to blood leakage into the tissue following needle insertion**), bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**), or infection (**which might occur if bacteria from the skin surface is introduced at the puncture site**).

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Insert an IV line, and inject the radionuclide IV on day 1; images are taken on days 1, 2, and 3. Imaging is done from the urinary bladder to the base of the skull to scan for a primary tumor. Each image takes 20 min, and total imaging time is 1 to 2 hr per day.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Advise the patient to drink increased amounts of fluids for 24 to 48 hrs to eliminate the radionuclide from the body, unless contraindicated. Inform the patient that radionuclide is eliminated from the body within 24 to 48 hr.
- ▶ Do not schedule other radionuclide tests 24 to 48 hr after this procedure.
- ▶ Observe/assess the needle site for bleeding, hematoma formation, and inflammation.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ If a woman who is breast-feeding must have a nuclear scan, she should not breast-feed the infant until the radionuclide has been eliminated. This could take as long as 3 days. Instruct her to express the milk and discard it

during the 3-day period to prevent cessation of milk production.

- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 48 hrs after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 48 hrs after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after the gloves are removed.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Advise the patient that SSKI (120 mg/day) will be administered for

10 days after the injection of the radionuclide. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH and challenge tests, aldosterone, angiography adrenal, catecholamines, CT abdomen, cortisol and challenge tests, HVA, MRI abdomen, metanephrines, potassium, renin, sodium, and VMA.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Adrenocorticotrophic Hormone (and Challenge Tests)

SYNONYM/ACRONYM: Corticotropin, ACTH.

COMMON USE: To assist in the investigation of adrenocortical dysfunction using ACTH and cortisol levels in diagnosing disorders such as Addison's disease, Cushing's disease, and Cushing's syndrome.

SPECIMEN: Plasma (2 mL) from a lavender-top (EDTA) tube for adrenocorticotrophic hormone (ACTH) and serum (1 mL) from a red-top tube for cortisol and 11-deoxycortisol. Collect specimens in a prechilled lavender- and red-top tubes. Gold-tiger- and green-top (heparin) tubes are also acceptable for cortisol, but take care to use the same type of collection container for serial measurements. Immediately transport specimen, tightly capped and in an ice slurry, to the laboratory. The specimens should be immediately processed. Plasma for ACTH analysis should be transferred to a plastic container.

Procedure	Indications	Medication Administered, Adult Dosage	Recommended Collection Times
ACTH stimulation, rapid test	Suspect adrenal insufficiency (Addison's disease) or congenital adrenal hyperplasia	1 mcg (low-dose physiologic protocol) cosyntropin IM or IV; 250 mcg (standard pharmacologic protocol) cosyntropin IM or IV	Three cortisol levels: baseline immediately before bolus, 30 min after bolus, and 60 min (optional) after bolus. Baseline and 30 min levels are adequate for accurate diagnosis using either dosage; low dose protocol sensitivity is most accurate for 30 min level only
Corticotropin-releasing hormone (CRH) stimulation	Differential diagnosis between ACTH-dependent conditions such as Cushing's disease (pituitary source) or Cushing's syndrome (ectopic source) and ACTH-independent conditions such as Cushing's syndrome (adrenal source)	IV dose of 1 mcg/kg human CRH	Eight cortisol and eight ACTH levels: baseline collected 15 min before injection, 0 min before injection, and then 5, 15, 30, 60, 120, and 180 min after injection
Dexamethasone suppression (overnight)	Differential diagnosis between ACTH-dependent conditions such as Cushing's disease (pituitary source) or Cushing's syndrome (ectopic source) and ACTH-independent conditions such as Cushing's syndrome (adrenal source)	Oral dose of 1 mg dexamethasone (Decadron) at 11 p.m.	Collect cortisol at 8 a.m. on the morning after the dexamethasone dose
Metyrapone stimulation (overnight)	Suspect hypothalamic/pituitary disease such as adrenal insufficiency, ACTH-dependent conditions such as Cushing's disease (pituitary source) or Cushing's syndrome (ectopic source), and ACTH-independent conditions such as Cushing's syndrome (adrenal source)	Oral dose of 30 mg/kg metyrapone with snack at midnight	Collect cortisol, 11-deoxycortisol, and ACTH at 8 a.m. on the morning after the metyrapone dose

IM = intramuscular, IV = intravenous.

NORMAL FINDINGS: (Method: Immunochemiluminescent assay for ACTH and cortisol; HPLC/MS-MS for 11-deoxycortisol)

A ACTH

Age	Conventional Units	SI Units (Conventional Units × 0.22)
Cord blood	50–570 pg/mL	11–125 pmol/L
Newborn	10–185 pg/mL	2–41 pmol/L
1 wk–9 yr	5–46 pg/mL	1.1–10.1 pmol/L
10–18 yr	6–55 pg/mL	1.3–12.1 pmol/L
19 yr–Adult		
Male supine (specimen collected in morning)	7–69 pg/mL	1.5–15.2 pmol/L
Female supine (specimen collected in morning)	6–58 pg/mL	1.3–12.8 pmol/L

Values may be unchanged or slightly elevated in healthy older adults. Long-term use of corticosteroids, to treat arthritis and autoimmune diseases, may suppress secretion of ACTH.

ACTH Challenge Tests

ACTH (Cosyntropin) Stimulated, Rapid Test	Conventional Units	SI Units (Conventional Units × 27.6)
Baseline	Cortisol greater than 5 mcg/dL	Greater than 138 nmol/L
30- or 60-min response	Cortisol 18–20 mcg/dL or incremental increase of 7 mcg/dL over baseline value	497–552 nmol/L or incremental increase of 193.2 nmol/L over baseline value

Corticotropin-Releasing Hormone Stimulated	Conventional Units	SI Units (Conventional Units × 27.6)
	Cortisol peaks at greater than 20 mcg/dL within 30–60 min	Greater than 552 nmol/L
	ACTH increases twofold to fourfold within 30–60 min	SI Units (Conventional Units × 0.22) Twofold to fourfold increase within 30–60 min

**Dexamethasone
Suppressed
Overnight Test**
Conventional Units
**SI Units (Conventional
Units × 27.6)**

 Cortisol less than
1.8 mcg/dL next day

Less than 49.7 nmol/L

**Metyrapone
Stimulated
Overnight Test**
Conventional Units
**SI Units (Conventional
Units × 27.6)**

 Cortisol less than
3 mcg/dL next day

Less than 83 nmol/L

ACTH greater than 75 pg/mL

**SI Units (Conventional
Units × 0.22)**

Greater than 16.5 pmol/L

 11-deoxycortisol greater than
7 mcg/dL

**SI Units (Conventional
Units × 28.9)**

Greater than 202 nmol/L

DESCRIPTION: Hypothalamic-releasing factor stimulates the release of ACTH from the anterior pituitary gland. ACTH stimulates adrenal cortex secretion of glucocorticoids, androgens, and, to a lesser degree, mineralocorticoids. Cortisol is the major glucocorticoid secreted by the adrenal cortex. ACTH and cortisol test results are evaluated together because a change in one normally causes a change in the other. ACTH secretion is stimulated by insulin, metyrapone, and vasopressin. It is decreased by dexamethasone. Cortisol excess from any source is termed *Cushing's syndrome*. Cortisol excess resulting from ACTH excess produced by the pituitary is termed *Cushing's disease*. ACTH levels

exhibit a diurnal variation, peaking between 6 and 8 a.m. and reaching the lowest point between 6 and 11 p.m. Evening levels are generally one-half to two-thirds lower than morning levels. Cortisol levels also vary diurnally, with the peak values occurring during between 6 and 8 a.m. in the morning and reaching the lowest levels between 8 p.m. and midnight in the evening. Specimens are typically collected at 8 a.m. and 4 p.m. This pattern may be reversed in individuals who sleep during daytime hours and are active during nighttime hours. Salivary cortisol levels are known to parallel blood levels and can be used to screen for Cushing's disease and Cushing's syndrome.

This procedure is contraindicated for

-  Patients with suspected adrenal insufficiency because it may induce an acute adrenal crisis, a life threatening condition, in patients whose adrenal function is already compromised.

INDICATIONS

- Determine adequacy of replacement therapy in congenital adrenal hyperplasia
- Determine adrenocortical dysfunction
- Differentiate between increased ACTH release with decreased cortisol levels and decreased ACTH release with increased cortisol levels

POTENTIAL DIAGNOSIS

ACTH Result

Because ACTH and cortisol secretion exhibit diurnal variation with values being highest in the morning, a lack of change in values from morning to evening is clinically significant. Decreased concentrations of hormones secreted by the pituitary gland and its target organs are observed in hypopituitarism. In primary adrenal insufficiency (Addison's disease), because of adrenal gland destruction by tumor, infectious process, or immune reaction, ACTH levels are elevated while cortisol levels are decreased. Both ACTH and cortisol levels are decreased in secondary adrenal insufficiency (i.e., secondary to pituitary insufficiency). Excess ACTH can be produced ectopically by various lung cancers such

as oat-cell carcinoma and large-cell carcinoma of the lung and by benign bronchial carcinoid tumor.

Challenge Tests and Results

The ACTH (cosyntropin) stimulated rapid test directly evaluates adrenal gland function and indirectly evaluates pituitary gland and hypothalamus function. Cosyntropin is a synthetic form of ACTH. A baseline cortisol level is collected before the injection of cosyntropin. Specimens are subsequently collected at 30- and 60-min intervals. If the adrenal glands function normally, cortisol levels rise significantly after administration of cosyntropin.

The CRH stimulation test works as well as the dexamethasone suppression test (DST) in distinguishing Cushing's disease from conditions in which ACTH is secreted ectopically (e.g., tumors not located in the pituitary gland that secrete ACTH). Patients with pituitary tumors tend to respond to CRH stimulation, whereas those with ectopic tumors do not. Patients with adrenal insufficiency demonstrate one of three patterns depending on the underlying cause:

- *Primary adrenal insufficiency—high baseline ACTH (in response to IV-administered ACTH) and low cortisol levels pre- and post-IV ACTH.*
- *Secondary adrenal insufficiency (pituitary)—low baseline ACTH that does not respond to ACTH stimulation. Cortisol levels do not increase after stimulation.*
- *Tertiary adrenal insufficiency (hypothalamic)—low baseline*

ACTH with an exaggerated and prolonged response to stimulation. Cortisol levels usually do not reach 20 mcg/dL.

(The DST is useful in differentiating the causes of increased cortisol levels. Dexamethasone is a synthetic glucocorticoid that is significantly more potent than cortisol. It works by negative feedback. It suppresses the release of ACTH in patients with a normal hypothalamus. A cortisol level less than 1.8 mcg/dL usually excludes Cushing's syndrome. With the DST, a baseline morning cortisol level is collected, and the patient is given a 1-mg dose of dexamethasone at bedtime. A second specimen is collected the following morning. If cortisol levels have not been suppressed, adrenal adenoma is suspected. The DST also produces abnormal results in the presence of certain psychiatric illnesses [e.g., endogenous depression]).

The metyrapone stimulation test is used to distinguish corticotropin-dependent causes (pituitary Cushing's disease and ectopic Cushing's disease) from corticotropin-independent causes (e.g., carcinoma of the lung or thyroid) of increased cortisol levels. Metyrapone inhibits the conversion of 11-deoxycortisol to cortisol. Cortisol levels should decrease to less than 3 mcg/dL if normal pituitary stimulation by ACTH occurs after an oral dose of metyrapone. Specimen collection and administration of the medication are performed as with the overnight dexamethasone test.

Increased in

Overproduction of ACTH can occur as a direct result of either

disease (e.g., primary or ectopic tumor that secretes ACTH) or stimulation by physical or emotional stress, or it can be an indirect response to abnormalities in the complex feedback mechanisms involving the pituitary gland, hypothalamus, or adrenal glands.

ACTH Increased in

- Addison's disease (*primary adrenocortical hypofunction*)
- Carcinoid syndrome
- Congenital adrenal hyperplasia
- Cushing's disease (*pituitary-dependent adrenal hyperplasia*)
- Cushing's syndrome (*ectopic secretion of ACTH*)
- Depression
- Ectopic ACTH-producing tumors
- Menstruation
- Nelson's syndrome (*ACTH-producing pituitary tumors*)
- Non-insulin-dependent diabetes
- Pregnancy
- Sepsis
- Septic shock

Decreased in

Secondary adrenal insufficiency due to hypopituitarism (inadequate production by the pituitary) can result in decreased levels of ACTH. Conditions that result in overproduction or availability of high levels of cortisol can also result in decreased levels of ACTH.

ACTH Decreased in

- Adrenal adenoma
- Adrenal cancer
- Cushing's syndrome
- Exogenous steroid therapy

Summary of the Relationship Between Cortisol and ACTH Levels in Conditions Affecting the Adrenal and Pituitary Glands

Disease	Cortisol Level	ACTH Level
Addison's disease (adrenal insufficiency)	Decreased	Increased
Cushing's disease (pituitary adenoma)	Increased	Increased
Cushing's syndrome related to ectopic source of ACTH	Increased	Increased
Cushing's syndrome (ACTH independent; adrenal cancer or adenoma)	Increased	Decreased
Congenital adrenal hyperplasia	Decreased	Increased

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase ACTH levels include insulin, metoclopramide, metyrapone, mifepristone (RU 486), and vasopressin.
- Drugs that may decrease ACTH levels include corticosteroids (e.g., dexamethasone) and pravastatin.
- Test results are affected by the time the test is done because ACTH levels vary diurnally, with the highest values occurring between 6 and 8 a.m. and the lowest values occurring at night. Samples should be collected at the same time of day, between 6 and 8 a.m.
- Excessive physical activity can produce elevated levels.
- Metyrapone may cause gastrointestinal distress and/or confusion. Administer oral dose of metyrapone with milk and snack.
- Rapid clearance of metyrapone, resulting in falsely increased cortisol levels, may occur if the patient is taking drugs that enhance steroid metabolism (e.g., phenytoin, rifampin, phenobarbital, mitotane, and corticosteroids). The requesting health-care provider (HCP) should be consulted prior to a metyrapone stimulation test regarding a decision to withhold these medications.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fluid volume (<i>Related to loss of water secondary to vomiting; diarrhea</i>)	Deficient: hypotension; decreased cardiac output; decreased urinary output; dry skin/mucous membranes; poor skin turgor; sunken eyeballs; increased urine specific gravity; hemoconcentration	Monitor intake and output; assess for symptoms of dehydration (dry skin, dry mucous membranes, poor skin turgor, sunken eyeballs); monitor and trend vital signs; monitor for symptoms of poor cardiac output (rapid, weak, thready pulse); monitor and trend daily weight; collaborate with physician with administration of IV

Problem	Signs & Symptoms	Interventions
		fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit, sodium); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes, as ordered; adjust diuretics, as appropriate
Infection risk <i>(Related to impaired immune response secondary to elevated cortisol level)</i>	Delayed wound healing; inhibited collagen formation; impaired blood flow to edematous tissues; symptoms of infection (temperature; increased heart rate; increased blood pressure; shaking; chills; mottled skin; lethargy; fatigue; swelling; edema; pain; localized pressure; diaphoresis; night sweats; confusion; vomiting; nausea; headache)	Decrease exposure to environment by placing the patient in a private room; monitor and trend vital signs; monitor and trend laboratory values that would indicate an infection (WBC, CRP); promote good hygiene; assist with hygiene, as needed; administer prescribed antibiotics, antipyretics; use cooling measures; administer prescribed IV fluids; monitor vital signs and trend temperatures; encourage oral fluids; adhere to standard or universal precautions; isolate as appropriate; obtain cultures, as ordered; encourage lightweight clothing and bedding
Injury risk <i>(Related to poor wound healing; decreased bone density; capillary fragility)</i>	Easy bruising; blood in stool; skin breakdown; fracture; poor wound healing	Assess for bruising; assess stool for occult blood; assess for skin breakdown; assess wound for healing progress; facilitate ordered bone density screening

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- Patient Teaching:** Inform the patient this test can assist in evaluating the amount of hormone produced by the pituitary gland located at the base of the brain.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
 - ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
 - ▶ Note any recent procedures that can interfere with test results.
 - ▶ Obtain a list of the patient's current medications, especially drugs that enhance steroid metabolism, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
 - ▶ Weigh patient and report weight to pharmacy for dosing of metyrapone (30 mg/kg body weight).
 - ▶ Review the procedure with the patient. When ACTH hypersecretion is suspected, a second sample may be requested between 6 and 8 p.m. to determine if changes are the result of diurnal variation in ACTH levels. Inform the patient that more than one sample may be necessary to ensure accurate results, and samples are obtained at specific times to determine high and low levels of ACTH. Inform the patient that each specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
 - ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
 - ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
 - ▶ Drugs that enhance steroid metabolism may be withheld by medical direction prior to metyrapone stimulation testing.
 - ▶ Instruct the patient to refrain from strenuous exercise for 12 hr before the test and to remain in bed or at rest for 1 hr immediately before the test. Avoid smoking and alcohol use.
 - ▶ Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.
- ▶ pain, headache, dizziness, sedation, allergic rash, decreased white blood cell (WBC) count, and bone marrow depression. Signs and symptoms of overdose include cardiac arrhythmias, hypotension, dehydration, anxiety, confusion, weakness, impairment of consciousness, N/V, epigastric pain, diarrhea, hyponatremia, and hyperkalemia.
 - ▶ Ensure that strenuous exercise was avoided for 12 hr before the test and that 1 hr of bed rest was taken immediately before the test. Samples should be collected between 6 and 8 a.m.
 - ▶ Have emergency equipment readily available in case of adverse reaction to metyrapone.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
 - ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in prechilled collection containers as listed under the "Specimen" subheading.
 - ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
 - ▶ Promptly transport the specimen to the laboratory for processing and analysis. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

INTRATEST:**Potential Complications:**

Adverse reactions to metyrapone include nausea and vomiting (N/V), abdominal

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and offer support.

- ▶ Observe/assess the patient who has been administered metyrapone for signs and symptoms of an acute adrenal (addisonian) crisis which may include abdominal pain, nausea, vomiting, hypotension, tachycardia, tachypnea, dehydration, excessively increased perspiration of the face and hands, sudden and significant fatigue or weakness, confusion, loss of consciousness, shock, coma. Potential interventions include immediate corticosteroid replacement (IV or IM), airway protection and maintenance, administration of dextrose for hypoglycemia, correction of electrolyte imbalance, and rehydration with IV fluids.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. If a diagnosis of Cushing's disease is made, pituitary computed tomography (CT) or magnetic resonance imaging (MRI) may be indicated prior to surgery. If a diagnosis of ectopic corticotropin syndrome is made, abdominal CT or MRI may be indicated prior to surgery. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to resume normal activity as directed by the HCP.
- ▶ Provide contact information, if desired, for the Cushing's Support and Research Foundation (www.csrff.net).
- ▶ Reinforce information given by the patient's HCP regarding further

testing, treatment, or referral to another HCP.

- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient and family the effects of the disease process and associated treatments

Expected Patient Outcomes:

Knowledge

- ▶ States the importance of compliance with the recommended therapeutic regime to health maintenance
- ▶ States understanding of the necessity of altering the medication regime during times of illness and stress

Skills

- ▶ Demonstrates proficiency in the self-administration of prescribed steroids
- ▶ Adheres to the request to stand slowly to prevent orthostatic hypotension

Attitude

- ▶ Complies with the HCP's request to wear a medic alert bracelet indicating adrenal insufficiency and steroid use
- ▶ Complies with the HCP's request to increase oral fluid intake with a diet high in sodium and low in potassium (Addison's disease)

RELATED MONOGRAPHS:

- ▶ Related tests include cortisol and challenge tests, CT abdomen, CT pituitary, MRI abdomen, MRI pituitary, TSH, thyroxine, and US abdomen.
- ▶ See the Endocrine System table at the end of the book for related tests by body system.

Alanine Aminotransferase

SYNONYM/ACRONYM: Serum glutamic pyruvic transaminase (SGPT), ALT.

COMMON USE: To assess liver function related to liver disease and/or damage.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional & SI Units
Newborn–12 mo	13–45 units/L
13 mo–60 yr	
Male	10–40 units/L
Female	7–35 units/L
61–90 yr	
Male	13–40 units/L
Female	10–28 units/L
Greater than 90 yr	
Male	6–38 units/L
Female	5–24 units/L

Values may be slightly elevated in older adults due to the effects of medications and the presence of multiple chronic or acute diseases with or without muted symptoms.

DESCRIPTION: Alanine aminotransferase (ALT), formerly known as serum glutamic pyruvic transaminase (SGPT), is an enzyme produced by the liver. The highest concentration of ALT is found in liver cells; moderate amounts are found in kidney cells; and smaller amounts are found in heart, pancreas, spleen, skeletal muscle, and red blood cells. When liver damage occurs, serum levels of ALT may increase as much as 50 times normal, making this a sensitive test for evaluating liver function. ALT is part of a group of tests known as LFTs or liver function tests used to evaluate liver function: ALT, Albumin, Alkaline phosphatase, Aspartate aminotransferase (AST), Bilirubin, direct, Bilirubin, total, and Protein, total

This procedure is contraindicated for: N/A

INDICATIONS

- Compare serially with aspartate aminotransferase (AST) levels to track the course of liver disease
- Monitor liver damage resulting from hepatotoxic drugs
- Monitor response to treatment of liver disease, with tissue repair

indicated by gradually declining levels

POTENTIAL DIAGNOSIS

Increased in

Related to release of ALT from damaged liver, kidney, heart, pancreas, red blood cells, or skeletal muscle cells.

- Acute pancreatitis
- AIDS (related to hepatitis B co-infection)
- Biliary tract obstruction
- Burns (severe)
- Chronic alcohol abuse
- Cirrhosis
- Fatty liver
- Hepatic carcinoma
- Hepatitis
- Infectious mononucleosis
- Muscle injury from intramuscular injections, trauma, infection, and seizures (recent)
- Muscular dystrophy
- Myocardial infarction
- Myositis
- Pancreatitis
- Pre-eclampsia
- Shock (severe)

Decreased in

- Pyridoxal phosphate deficiency (*related to a deficiency of pyridoxal phosphate that results in decreased production of ALT*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase ALT levels by causing cholestasis include anabolic steroids, dapsone, estrogens, ethionamide, icterogenin, mepazine, methandriol, oral contraceptives, oxymetholone, propoxyphene, sulfonyleureas, and zidovudine.
- Drugs that may increase ALT levels by causing hepatocellular damage include acetaminophen (toxic), acetylsalicylic acid, anticonvulsants, asparaginase, carbutamide, cephalosporins, chloramphenicol, clofibrate,

cytarabine, danazol, dinitrophenol, enflurane, erythromycin, ethambutol, ethionamide, ethotoin, florantyrone, foscarnet, gentamicin, gold salts, halothane, ibufenac, indomethacin, interleukin-2, isoniazid, lincomycin, low-molecular-weight heparin, methexamide, metaxalone, methoxsalen,

methyldopa, methylthiouracil, naproxen, nitrofurans, oral contraceptives, probenecid, procainamide, and tetracyclines.

- Drugs that may decrease ALT levels include cyclosporine, interferons, metronidazole (affects enzymatic test methods), and ursodiol.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to organ inflammation and surrounding tissues; excessive alcohol intake; infection</i>)	Emotional symptoms of distress; crying; agitation; facial grimace; moaning; verbalization of pain; rocking motions; irritability; disturbed sleep; diaphoresis; altered blood pressure and heart rate; nausea; vomiting; self-report of pain; upper abdominal and gastric pain after eating fatty foods or alcohol intake with acute pancreatic disease; pain, which may be decreased or absent in chronic pancreatic disease	Collaborate with the patient and physician to identify the best pain management modality to provide relief; refrain from activities that may aggravate pain; use the application of heat or cold to the best effect in managing pain; monitor pain severity
Fluid volume (<i>Related to vomiting; decreased intake; compromised renal function; overly aggressive fluid resuscitation; overly aggressive diuresis</i>)	Overload: Edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values. Deficient: decreased urinary output, fatigue, and sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status	Complete a daily weight with monitoring of trends; accurate intake and output; collaborate with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate

(table continues on page 22)

Problem	Signs & Symptoms	Interventions
Nutrition (<i>Related to metabolic imbalances</i>)	Increased liver function tests; hyperglycemia with polyuria, weight loss, weakness, nausea, vomiting; hypocalcemia with confusion, intestinal cramping, diarrhea; hypertriglyceridemia; altered thiamine with weakness, confusion	with physician to adjust oral and intravenous fluids to provide optimal hydration status; administer replacement electrolytes, as ordered Administer enteral nutrition; administer parenteral nutrition; monitor laboratory values and collaborate with physician on replacement strategies; correlate laboratory values with IV fluid infusion and collaborate with the physician and pharmacist to adjust to patient needs; ensure adequate pain control; monitor vital signs for alterations associated metabolic imbalances
Gastrointestinal problems (<i>Related to altered motility; irritation of the GI tract; taste alterations; pancreatic and gastric secretions</i>)	Nausea; vomiting; abdominal distention; unexplained weight loss; steatorrhea; diarrhea; visible abdominal distention; ascites; diminished or absent bowel sounds	Perform nasogastric intubation (NGT) to remove gastric secretions and decrease pancreatic secretions which may result in autodigestion; monitor NGT for patency and amount of drainage; assess hydration status; assess bowel sounds frequently; measure abdominal girth to monitor degree of abdominal distention

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with evaluation of liver function and help identify disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle, and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding and hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased ALT levels may be associated with liver disease. Dietary recommendations may be indicated and vary depending on the severity of the condition. A low-protein diet may be in order if the patient's liver has lost the ability to process the end products of protein metabolism. A diet of soft foods may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs) rather than complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Recognize anxiety related to test results, and answer any questions or address any concerns voiced by the patient or family.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services. Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/diseasesconditions).
- ▶ Provide information regarding disease process and proactive activities that the patient can take in managing health.
- ▶ Provide samples of dietary selections that can support pancreatic and liver health and that are culturally appropriate.

Expected Patient Outcomes:

Knowledge

- ▶ The patient and family verbalize understanding of causative factors of pancreatitis and liver disease.
- ▶ The patient and family verbalize understanding that the disease can reoccur if not adhering to positive actions to change lifestyle.

Skills

- ▶ The patient creates a diet plan that supports liver and pancreatic health.
- ▶ The patient takes medication as prescribed to limit pancreatic secretions and decrease pain.

Attitude

- ▶ The patient agrees to seek counseling for alcohol abstinence.
- ▶ The patient agrees to control potential behaviors that could trigger future disease episodes.

RELATED MONOGRAPHS:

- ▶ Related tests include acetaminophen, ammonia, AST, bilirubin, biopsy liver, cholangiography percutaneous transhepatic, electrolytes, GGT, hepatitis antigens and antibodies, LDH, liver and spleen scan, US abdomen, and US liver.
- ▶ See the Hepatobiliary System table at the end of the book for related tests by body system.

Albumin and Albumin/Globulin Ratio

SYNONYM/ACRONYM: Alb, A/G ratio.

COMMON USE: To assess liver or kidney function and nutritional status.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Spectrophotometry) Normally the albumin/globulin (A/G) ratio is greater than 1.

Age	Conventional Units	SI Units (Conventional Units × 10)
Cord	2.8–4.3 g/dL	28–43 g/L
Newborn–7 d	2.6–3.6 g/dL	26–36 g/L
8–30 d	2–4.5 g/dL	20–45 g/L
1–3 mo	2–4.8 g/dL	20–48 g/L
4–6 mo	2.1–4.9 g/dL	21–49 g/L
7–12 mo	2.1–4.7 g/dL	21–47 g/L
1–3 yr	3.4–4.2 g/dL	34–42 g/L
4–6 yr	3.5–5.2 g/dL	35–52 g/L
7–19 yr	3.7–5.6 g/dL	37–56 g/L
20–40 yr	3.7–5.1 g/dL	37–51 g/L
41–60 yr	3.4–4.8 g/dL	34–48 g/L
61–90 yr	3.2–4.6 g/dL	32–46 g/L
Greater than 90 yr	2.9–4.5 g/dL	29–45 g/L

DESCRIPTION: Most of the body's total protein is a combination of albumin and globulins. Albumin, the protein present in the highest concentrations, is the main transport protein in the body for hormones, therapeutic drugs, calcium, magnesium, heme, and waste products such as bilirubin. Albumin also significantly affects plasma oncotic pressure, which regulates the distribution of body fluid between blood vessels, tissues, and cells. Albumin is synthesized in the liver. Low levels of albumin may be the result of either inadequate intake, inadequate production, or excessive loss. Albumin levels are more useful as

an indicator of chronic deficiency than of short-term deficiency. Hypoalbuminemia or low serum albumin, a level less than 3.4 g/dL, can stem from many causes and may be a useful predictor of mortality. Normally albumin is not excreted in urine. However, in cases of kidney damage some albumin may be lost due to decreased kidney function as seen in nephrotic syndrome, and in pregnant women with pre-eclampsia and eclampsia.

Albumin levels are affected by posture. Results from specimens collected in an upright posture are higher than results from specimens collected in a supine position.

The albumin/globulin (A/G) ratio is useful in the evaluation of liver and kidney disease. The ratio is calculated using the following formula:

$$\text{albumin}/(\text{total protein} - \text{albumin})$$

where globulin is the difference between the total protein value and the albumin value. For example, with a total protein of 7 g/dL and albumin of 4 g/dL, the A/G ratio is calculated as $4/(7 - 4)$ or $4/3 = 1.33$. A reversal in the ratio, where globulin exceeds albumin (i.e., ratio less than 1.0), is clinically significant.

This procedure is contraindicated for: N/A

INDICATIONS

- Assess nutritional status of hospitalized patients, especially geriatric patients
- Evaluate chronic illness
- Evaluate liver disease

POTENTIAL DIAGNOSIS

Increased in

Any condition that results in a decrease of plasma water (e.g., dehydration); look for increase in hemoglobin and hematocrit. Decreases in the volume of intravascular liquid automatically result in concentration of the components present in the remaining liquid, as reflected by an elevated albumin level.

- Hyperinfusion of albumin

Decreased in

- **Insufficient intake:**
Malabsorption (related to lack of amino acids available for protein synthesis)
Malnutrition (related to insufficient dietary source of amino acids required for protein synthesis)

- **Decreased synthesis by the liver:**

Acute and chronic liver disease (e.g., alcoholism, cirrhosis, hepatitis) (evidenced by a decrease in normal liver function; the liver is the body's site of protein synthesis)

Genetic analbuminemia (related to genetic inability of liver to synthesize albumin)

- **Inflammation and chronic diseases result in production of acute-phase reactant and other globulin proteins; the increase in globulins causes a corresponding relative decrease in albumin:**

Amyloidosis

Bacterial infections

Monoclonal gammopathies (e.g., multiple myeloma, Waldenström's macroglobulinemia)

Neoplasm

Parasitic infestations

Peptic ulcer

Prolonged immobilization

Rheumatic diseases

Severe skin disease

- **Increased loss over body surface:**

Burns (evidenced by loss of interstitial fluid albumin)

Enteropathies (e.g., gluten sensitivity, Crohn's disease, ulcerative colitis, Whipple's disease) (evidenced by sensitivity to ingested substances or related to inadequate absorption from intestinal loss)

Fistula (gastrointestinal or lymphatic) (related to loss of sequestered albumin from general circulation)

Hemorrhage (related to fluid loss)

Kidney disease (related to loss from damaged renal tubules)

Pre-eclampsia (evidenced by excessive renal loss)

Rapid hydration or overhydration (evidenced by dilution effect)

Repeated thoracentesis or paracentesis (related to removal of albumin in accumulated third-space fluid)

- **Increased catabolism:**

Cushing's disease (related to excessive cortisol induced protein metabolism)

Thyroid dysfunction (related to overproduction of albumin binding thyroid hormones)

• **Increased blood volume (hypervolemia):**

Congestive heart failure (*evidenced by dilution effect*)

Pre-eclampsia (*related to fluid retention*)

Pregnancy (*evidenced by increased circulatory volume from placenta and fetus*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase albumin levels include carbamazepine, furosemide, phenobarbital, and prednisolone.
- Drugs that may decrease albumin levels include acetaminophen (poisoning), amiodarone, asparaginase, dextran, estrogens, ibuprofen, interleukin-2, methotrexate, methyldopa, niacin, nitrofurantoin, oral contraceptives, phenytoin, prednisone, and valproic acid.
- Availability of administered drugs is affected by variations in albumin levels.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- **Patient Teaching:** Inform the patient this test can assist with evaluation of liver and kidney function, as well as chronic disease.
- Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex. The patient should be assessed for signs of edema or ascites.
- Obtain a history of the patient's gastrointestinal, genitourinary, and hepatobiliary systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.

- Obtain a list of the patient's current medications including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- **Nutritional Considerations:** Dietary recommendations may be indicated and will vary depending on the severity of the condition. Ammonia levels may be used to determine whether protein

should be added to or reduced from the diet.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Recognize anxiety related to test results and answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Availability of administered drugs is affected by variations in albumin levels. Patients receiving therapeutic drug treatments should have their drug levels monitored when levels of the transport protein, albumin, are decreased in

order to prevent development of toxic drug concentrations. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, ALP, ammonia, anti-smooth muscle antibodies, AST, bilirubin, biopsy liver, CBC hematocrit, CBC hemoglobin, CT biliary tract and liver, GGT, hepatitis antibodies and antigens, KUB studies, laparoscopy abdominal, liver scan, MRI abdomen, osmolality, potassium, prealbumin, protein total and fractions, radiofrequency ablation liver, sodium, US abdomen, and US liver.
- ▶ See the Gastrointestinal, Genitourinary, and Hepatobiliary systems tables at the end of the book for related tests by body system.

Aldolase

SYNONYM/ACRONYM: ALD.

COMMON USE: To assist in the diagnosis of muscle-wasting diseases such as muscular dystrophy or other diseases that cause muscle and cellular damage such as hepatitis and cirrhosis of the liver.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional & SI Units
Newborn–30 d	6–32 units/L
1 mo–2 yr	3.4–11.8 units/L
3–6 yr	2.7–8.8 units/L
7–17 yr	3.3–9.7 units/L
Adult	Less than 8.1 units/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

ALD is released from any damaged cell in which it is stored, so diseases of skeletal muscle, cardiac muscle, pancreas, red blood cells, and liver that cause cellular destruction demonstrate elevated ALD levels.

- Carcinoma (lung, breast, and genitourinary tract and metastasis to liver)
- Dermatomyositis
- Duchenne's muscular dystrophy

- Hepatitis (acute viral or toxic)
- Limb girdle muscular dystrophy
- Myocardial infarction
- Pancreatitis (acute)
- Polymyositis
- Severe crush injuries
- Tetanus
- Trichinosis (*related to myositis*)

Decreased in

- Hereditary fructose intolerance (*evidenced by hereditary deficiency of the aldolase B enzyme*)
- *Late stages of muscle-wasting diseases in which muscle mass has significantly diminished*

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Aldosterone

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in the diagnosis of primary hyperaldosteronism disorders such as Conn's syndrome and Addison's disease. Blood levels fluctuate with dehydration and fluid overload. This test can be used in evaluation of hypertension.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) or lavender-top (EDTA) tube is also acceptable.

NORMAL FINDINGS: (Method: Radioimmunoassay)

Age	Conventional Units	SI Units (Conventional Units × 0.0277)
Cord blood	40–200 ng/dL	1.11–5.54 nmol/L
3 days–1 wk	7–184 ng/dL	0.19–5.09 nmol/L
1 mo–1 yr	5–90 ng/dL	0.14–2.49 nmol/L
13–23 mo	7–54 ng/dL	0.19–1.49 nmol/L
2–10 yr		
Supine	3–35 ng/dL	0.08–0.97 nmol/L
Upright	5–80 ng/dL	0.14–2.22 nmol/L
11–15 yr		
Supine	2–22 ng/dL	0.06–0.61 nmol/L
Upright	4–48 ng/dL	0.11–1.33 nmol/L
Adult		
Supine	3–16 ng/dL	0.08–0.44 nmol/L
Upright	7–30 ng/dL	0.19–0.83 nmol/L
Older Adult	Levels decline with age	

These values reflect a normal-sodium diet. Values for a low-sodium diet are three to five times higher.

DESCRIPTION: Aldosterone is a mineralocorticoid secreted by the zona glomerulosa of the adrenal cortex and is regulated by the renin-angiotensin system. Changes in renal blood flow trigger or suppress release of renin from the glomeruli. The presence of circulating renin stimulates the liver to produce angiotensin I. Angiotensin I is converted by the lung and kidneys into angiotensin II, a potent trigger for the release of aldosterone. Aldosterone and the renin-angiotensin system work together to regulate sodium and potassium levels. Aldosterone acts to increase sodium reabsorption in the renal tubules. This results in excretion of potassium, increased water retention, increased blood volume, and increased blood pressure. This test is of little diagnostic value in differentiating primary and secondary aldosteronism unless plasma renin activity is measured simultaneously (see monograph titled “Renin”). A variety of factors influence serum aldosterone levels, including sodium intake, certain medications, and activity. Secretion of aldosterone is also affected by ACTH, a pituitary hormone that primarily stimulates secretion of glucocorticoids and minimally affects secretion of mineralocorticosteroids. Patients with serum potassium less than 3.6 mEq/L and 24-hour urine potassium greater than 40 mEq/L fit the general criteria to test for aldosteronism. Renin is low in primary aldosteronism and high in secondary aldosteronism. A ratio of plasma aldosterone to plasma renin activity greater than 50 is significant. Ratios greater than 20 obtained after unchallenged screening may indicate the need for further evaluation

with a sodium-loading protocol. A captopril protocol can be substituted for patients who may not tolerate the sodium-loading protocol.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate hypertension of unknown cause, especially with hypokalemia not induced by diuretics
- Investigate suspected hyperaldosteronism, as indicated by elevated levels
- Investigate suspected hypoaldosteronism, as indicated by decreased levels

POTENTIAL DIAGNOSIS

Increased in

Increased With Decreased Renin Levels

Primary hyperaldosteronism (evidenced by overproduction related to abnormal adrenal gland function):

- Adenomas (Conn’s syndrome)
- Bilateral hyperplasia of the aldosterone-secreting zona glomerulosa cells

Increased With Increased Renin Levels

Secondary hyperaldosteronism (related to conditions that increase renin levels, which then stimulate aldosterone secretion):

- Bartter’s syndrome (*related to excessive loss of potassium by the kidneys, leading to release of renin and subsequent release of aldosterone*)
- Cardiac failure (*related to diluted concentration of sodium by increased blood volume*)
- Chronic obstructive pulmonary disease

- Cirrhosis with ascites formation (*related to diluted concentration of sodium by increased blood volume*)
- Diuretic abuse (*related to direct stimulation of aldosterone secretion*)
- Hypovolemia (*secondary to hemorrhage and transudation*)
- Laxative abuse (*related to direct stimulation of aldosterone secretion*)
- Nephrotic syndrome (*related to excessive renal protein loss, development of decreased oncotic pressure, fluid retention, and diluted concentration of sodium*)
- Starvation (after 10 days) (*related to diluted concentration of sodium by development of edema*)
- Thermal stress (*related to direct stimulation of aldosterone secretion*)
- Toxemia of pregnancy (*related to diluted concentration of sodium by increased blood volume evidenced by edema; placental corticotropin-releasing hormone stimulates production of maternal adrenal hormones that can also contribute to edema*)
- Excess secretion of deoxycorticosterone (*related to suppression of ACTH production by cortisol, which in turn affects aldosterone secretion*)
- Turner's syndrome (25% of cases) (*related to congenital adrenal hyperplasia resulting in underproduction of aldosterone and overproduction of androgens*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase aldosterone levels include amiloride, ammonium chloride, angiotensin, angiotensin II, dobutamine, dopamine, endralazine, fenoldopam, hydralazine, hydrochlorothiazide, laxatives (abuse), metoclopramide, nifedipine, opiates, potassium, spironolactone, and zacopride.
- Drugs that may decrease aldosterone levels include atenolol, captopril, carvedilol, cilazapril, enalapril, fadrozole, glycyrrhiza (licorice), ibopamine, indomethacin, lisinopril, nicardipine, NSAIDs, perindopril, ranitidine, saline, sinorphan, and verapamil. Prolonged heparin therapy also decreases aldosterone levels.
- Upright body posture, stress, strenuous exercise, and late pregnancy can lead to increased levels.
- Recent radioactive scans or radiation within 1 wk before the test can interfere with test results when radioimmunoassay is the test method.
- Diet can significantly affect results. A low-sodium diet can increase serum aldosterone, whereas a high-sodium diet can decrease levels. Decreased serum sodium and elevated serum potassium increase aldosterone secretion. Elevated serum sodium and decreased serum potassium suppress aldosterone secretion.

Decreased in

Without Hypertension

- Addison's disease (*related to lack of function in the adrenal cortex*)
- Hypoaldosteronism (*secondary to renin deficiency*)
- Isolated aldosterone deficiency

With Hypertension

- Acute alcohol intoxication (*related to toxic effects of alcohol on adrenal gland function and therefore secretion of aldosterone*)
- Diabetes (*related to impaired conversion of prerenin to renin by damaged kidneys, resulting in decreased aldosterone*)

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fluid volume (<i>Related to hypovolemia associated with adrenal insufficiency; cortisol insufficiency; hyponatremia, vomiting, diarrhea</i>)	Deficient: hypotension; decreased cardiac output; decreased urinary output; dry skin/mucous membranes; poor skin turgor; sunken eyeballs; increased urine specific gravity; hemoconcentration; weakness, lethargy, dizziness, tachycardia, low sodium, elevated potassium, hypoglycemia	Monitor intake and output; assess for symptoms of dehydration (dry skin, dry mucous membranes, poor skin turgor, sunken eyeballs), monitor and trend vital signs; monitor for symptoms of poor cardiac output (rapid, weak, thready pulse); monitor daily weight with monitoring of trends; collaborate with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit, sodium); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes, as ordered; adjust diuretics, as appropriate, monitor and trend blood glucose
Tissue perfusion (<i>Related to inadequate fluid volume; decreased cortisol levels</i>)	Hypotension; dizziness; cool extremities; pallor; capillary refill greater than 3 sec in fingers and toes; weak pedal pulses; altered level of consciousness; altered sensation; urinary output less than 30 mL/hr	Monitor blood pressure; assess for dizziness; assess extremities for skin temperature, color, warmth; assess capillary refill; assess pedal pulses; monitor for numbness, tingling, hyperesthesia, hypoesthesia; monitor for DVT; carefully use heat and cold on affected areas; use foot cradle to keep pressure off of affected body parts; provide oxygen as required

(table continues on page 32)

Problem	Signs & Symptoms	Interventions
Self-care (<i>Related to dizziness, fatigue, weakness, vomiting, diarrhea, anorexia</i>)	Difficulty fastening clothing; difficulty performing personal hygiene; inability to maintain appropriate appearance; difficulty with independent mobility	Reinforce self-care techniques as taught by occupational therapy; ensure that the patient has adequate time to perform self-care; encourage use of assistive devices to maintain independence; ask if there is any interference with lifestyle activities; assess the ability to engage in activities of daily living
Mobility (<i>Related to dizziness, fatigue, weakness secondary to adrenal insufficiency and decreased cortisol levels</i>)	Weakness, muscle wasting, pain in muscles and joints, decreased endurance, activity intolerance, difficult purposeful movement, reluctance to attempt to engage in activity	Provide assistance with mobility with encouraged use of assistive devices; assess emotional response to limited mobility; assess willingness to participate in activity; assess environment of safety concerns; assess the ability to engage in activities of daily living; encourage early mobility to retain as much independent function as possible; allow sufficient time to perform tasks without being rushed; assess nutritional intake

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
 - ▶ **Patient Teaching:** Inform the patient this test evaluates dehydration and can assist in identification of the causes of muscle weakness or high blood pressure.
 - ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
 - ▶ Obtain a history of known or suspected fluid or electrolyte imbalance, hypertension, renal function, or stage of pregnancy. Note the amount of sodium ingested in the diet over the past 2 wk.
 - ▶ Obtain a history of the patient's endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
 - ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
 - ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Inform the patient that multiple specimens may be required. Address concerns about pain and explain that there may be some discomfort during the venipuncture. Aldosterone levels may also be collected directly from the left and right adrenal veins. This procedure is performed by a radiologist via catheterization and takes approximately 1 hr.
 - ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
 - ▶ Inform the patient that the required position, supine/lying down or upright/sitting up, must be maintained for 2 hr before specimen collection.

- ▶ Prescribe the patient a normal-sodium diet (1 to 2 g of sodium per day) 2 to 4 wk before the test. Protocols may vary among facilities.
- ▶ Under medical direction, the patient should avoid diuretics, antihypertensive drugs and herbals, and cyclic progestogens and estrogens for 2 to 4 wk before the test. The patient should also be advised to avoid consuming anything that contains licorice for 2 wk before the test. Licorice inhibits short-chain dehydrogenase/reductase enzymes. These enzymes normally prevent cortisol from binding to aldosterone receptor sites in the kidney. In the absence of these enzymes, cortisol acts on the kidney and triggers the same effects as aldosterone, which include increased potassium excretion, sodium retention, and water retention. Aldosterone levels are not affected by licorice ingestion, but the simultaneous measurements of electrolytes may provide misleading results.

INTRATEST:**Potential Complications:** N/A

- ▶ Ensure that the patient has complied with dietary, medication, and pretesting preparations regarding activity.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, time of collection, patient position (upright or supine), and exact source of specimen (peripheral versus arterial). Perform a venipuncture after the patient has been in the upright (sitting or standing) position for 2 hr. If a supine specimen is requested on an inpatient, the specimen should be collected early in the morning before rising.
- ▶ Remove the needle, and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture

site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen on ice to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, medication, and activity as directed by the HCP.
- ▶ Instruct the patient to notify the HCP of any signs and symptoms of dehydration or fluid overload related to elevated aldosterone levels or compromised sodium regulatory mechanisms.
- ▶ **Nutritional Considerations:** Aldosterone levels are involved in the regulation of body fluid volume. Educate patients about the importance of proper water balance. Tap water may also contain other nutrients. Water-softening systems replace minerals (e.g., calcium, magnesium, iron) with sodium, so caution should be used if a low-sodium diet is prescribed.
- ▶ **Nutritional Considerations:** Because aldosterone levels affect sodium levels, some consideration may be given to dietary adjustment if sodium allowances need to be regulated. Educate patients with low sodium levels that the major source of dietary sodium is table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through consumption of processed foods. Patients who need to follow low-sodium diets should avoid beverages such as colas, ginger ale, Gatorade, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels. Potassium is present in all plant and animal cells,

making dietary replacement simple. An HCP or nutritionist should be consulted before considering the use of salt substitutes.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient and/or family.
- ▶ Teach the patient to report any gastric distress or dark stools associated with prescribed medication use.

Expected Patient Outcomes:

Knowledge

- ▶ States the importance of taking prescribed medication regularly

- ▶ States understanding that medication will need to be taken continuously for the rest of their lives

Skills

- ▶ Identifies diet selections that are lower in potassium and higher in sodium and protein
- ▶ Performs and accurately records weight daily

Attitude

- ▶ Adheres to medication regime with the understanding that sudden cessation is dangerous
- ▶ Complies with the request to report infections, or stressors, to HCP for medication adjustments

RELATED MONOGRAPHS:

- ▶ Related tests include adrenal gland scan, biopsy kidney, BUN, catecholamines, cortisol, creatinine, glucose, magnesium, osmolality, potassium, protein urine, renin, sodium, and UA.
- ▶ See the Endocrine and Genitourinary systems tables at the end of the book for related tests by body system.

Alkaline Phosphatase and Isoenzymes

SYNONYM/ACRONYM: Alk Phos, ALP and fractionation, heat-stable ALP.

COMMON USE: To assist in the diagnosis of liver cancer and cirrhosis, or bone cancer and bone fracture.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Spectrophotometry for total alkaline phosphatase, inhibition/electrophoresis for fractionation)

Total ALP	Conventional & SI Units	Bone Fraction	Liver Fraction
0–30 d			
Male	75–375 units/L		
Female	65–350 units/L		
1–11 mo			
Male	70–350 units/L		
Female	80–330 units/L		
1–5 yr			
Male	56–350 units/L	39–308 units/L	Less than 8–101 units/L
Female	73–378 units/L	56–300 units/L	Less than 8–53 units/L
6–7 yr			
Male	70–364 units/L	50–319 units/L	Less than 8–76 units/L
Female	73–378 units/L	56–300 units/L	Less than 8–53 units/L
8 yr			
Male	70–364 units/L	50–258 units/L	Less than 8–62 units/L
Female	98–448 units/L	78–353 units/L	Less than 8–62 units/L
9–12 yr			
Male	112–476 units/L	78–339 units/L	Less than 8–81 units/L

21 yr and older			
Male	35–142 units/L	11–73 units/L	0–93 units/L
Female	25–125 units/L	11–73 units/L	0–93 units/L

Values may be slightly elevated in older adults.

DESCRIPTION: Alkaline phosphatase (ALP) is an enzyme found in the liver; in Kupffer cells lining the biliary tract; and in bones, intestines, and placenta. Additional sources of ALP include the proximal tubules of the kidneys, pulmonary alveolar cells, germ cells, vascular bed, lactating mammary glands, and granulocytes of circulating blood. ALP is referred to as alkaline because it functions optimally at a pH of 9.0. This test is most useful for determining the presence of liver or bone disease.

Isoelectric focusing methods can identify 12 isoenzymes of ALP. Certain cancers produce small amounts of distinctive Regan and Nagao ALP isoenzymes. Elevations in three main ALP isoenzymes, however, are of clinical significance: ALP₁ of liver origin, ALP₂ of bone origin, and ALP₃ of intestinal origin (normal elevations are present in Lewis antibody positive individuals with blood types O and B). ALP levels vary by age and gender. Values in children are higher than in adults because of the level of bone growth and development. An immunoassay method is available for measuring bone-specific ALP as an indicator of increased bone turnover and estrogen deficiency in postmenopausal women.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate signs and symptoms of various disorders associated with

elevated ALP levels, such as biliary obstruction, hepatobiliary disease, and bone disease, including malignant processes

- Differentiate obstructive hepatobiliary tract disorders from hepatocellular disease; greater elevations of ALP are seen in the former
- Determine effects of renal disease on bone metabolism
- Determine bone growth or destruction in children with abnormal growth patterns

POTENTIAL DIAGNOSIS

Increased in

Related to release of alkaline phosphatase from damaged bone, biliary tract, and liver cells

- **Liver disease:**
 - Biliary atresia
 - Biliary obstruction (acute cholecystitis, cholelithiasis, intrahepatic cholestasis of pregnancy, primary biliary cirrhosis)
 - Cancer
 - Chronic active hepatitis
 - Cirrhosis
 - Diabetes (diabetic hepatic lipidosis)
 - Extrahepatic duct obstruction
 - Granulomatous or infiltrative liver diseases (sarcoidosis, amyloidosis, TB)
 - Infectious mononucleosis
 - Intrahepatic biliary hypoplasia
 - Toxic hepatitis
 - Viral hepatitis
- **Bone disease:**
 - Healing fractures
 - Metabolic bone diseases (rickets, osteomalacia)
 - Metastatic tumors in bone
 - Osteogenic sarcoma
 - Osteoporosis
 - Paget's disease (osteitis deformans)
- **Other conditions:**
 - Advanced pregnancy (*related to additional sources: placental tissue and new fetal bone growth; marked*

decline is seen with placental insufficiency and imminent fetal demise)

Cancer of the breast, colon, gallbladder, lung, or pancreas
 Congestive heart failure
 Familial hyperphosphatemia
 Hyperparathyroidism
 Perforated bowel
 Pneumonia
 Pulmonary and myocardial infarctions
 Pulmonary embolism
 Ulcerative colitis

Decreased in

- Anemia (severe)
- Celiac disease
- Folic acid deficiency
- HIV-1 infection
- Hypervitaminosis D
- Hypophosphatasia (*related to insufficient phosphorus source for ALP production; congenital and rare*)
- Hypothyroidism (characteristic in infantile and juvenile cases)
- Nutritional deficiency of zinc or magnesium
- Pernicious anemia
- Scurvy (*related to vitamin C deficiency*)
- Whipple's disease
- Zollinger-Ellison syndrome

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase ALP levels by causing cholestasis include anabolic steroids, erythromycin, ethionamide, gold salts, imipramine, interleukin-2, isocarboxazid, nitrofurans, oral contraceptives, phenothiazines, sulfonamides, and tolbutamide.
- Drugs that may increase ALP levels by causing hepatocellular damage include acetaminophen (toxic), amiodarone, anticonvulsants, arsenicals, asparaginase, bromocriptine, captopril, cephalosporins, chloramphenicol, enflurane,

ethionamide, foscarnet, gentamicin, indomethacin, lincomycin, methyldopa, naproxen, nitrofurans, probenecid, procainamide, progesterone, ranitidine, tobramycin, tolcapone, and verapamil.

- Drugs that may cause an overall decrease in ALP levels include alendronate, azathioprine, calcitriol, clofibrate, estrogens with estrogen replacement therapy, and ursodiol.
- Hemolyzed specimens may cause falsely elevated results.
- Elevations of ALP may occur if the patient is nonfasting, usually 2 to 4 hr after a fatty meal, and especially if the patient is a Lewis-positive secretor of blood group B or O.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with determining the presence of liver or bone disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hepatobiliary and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding and hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased ALP levels may be associated with liver disease. Dietary recommendations may be indicated and vary depending on the severity of the condition. A low-protein diet may be in order if the patient's liver has lost the ability to process the end products of protein metabolism. A diet of soft foods may

be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs) rather than complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include acetaminophen, ALT, albumin, ammonia, anti-DNA antibodies, AMA/ASMA, ANA, α_1 -antitrypsin, α_1 -antitrypsin phenotyping, AST, bilirubin, biopsy bone, biopsy liver, bone scan, BMD, calcium, ceruloplasmin, collagen cross-linked telopeptides, C3 and C4, complements, copper, ERCP, GGT, hepatitis antigens and antibodies, hepatobiliary scan, KUB studies, magnesium, MRI abdomen, MRI venography, osteocalcin, PTH, phosphorus, potassium, protein, protein electrophoresis, PT/INR, salicylate, sodium, US abdomen, US liver, vitamin D, and zinc.
- ▶ See the Hepatobiliary and Musculoskeletal systems tables at the end of the book for related tests by body system.

Allergen-Specific Immunoglobulin E

SYNONYM/ACRONYM: Allergen profile, radioallergosorbent test (RAST), ImmunoCAP[®] Specific IgE.

COMMON USE: To assist in identifying environmental allergens responsible for causing allergic reactions.

SPECIMEN: Serum (2 mL per group of six allergens, 0.5 mL for each additional individual allergen) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Radioimmunoassay or fluorescence enzyme immunoassay)

RAST Scoring Method (Radioimmunoassay) and ImmunoCAP [®] Scoring Guide (Fluorescence Enzyme Immunoassay)	Conventional and SI units Allergen Specific IgE
Specific IgE Allergen Antibody Level	kU/L
Absent or undetectable allergy	Less than 0.35
Low allergy	0.35–0.7
Moderate allergy	0.71–3.5
High allergy	3.51–17.5
Very high allergy	17.5–50
Very high allergy	51–100
Very high allergy	Greater than 100

DESCRIPTION: Allergen-specific immunoglobulin E (IgE) is generally requested for groups of allergens commonly known to incite an allergic response in the affected individual. The test is based on the use of a radiolabeled or non-radiolabeled anti-IgE reagent to detect IgE in the patient's serum, produced in response to specific allergens. The panels include allergens such as animal dander, antibiotics, dust, foods, grasses, insects, trees, mites, molds, venom, and weeds. Allergen testing is useful for evaluating the cause of hay fever, extrinsic asthma, atopic eczema, respiratory

allergies, and potentially fatal reactions to insect venom, penicillin, and other drugs or chemicals. RAST and non-radiolabeled methods are alternatives to skin test energy and provocation procedures, which can be inconvenient, painful, and potentially hazardous to patients. ImmunoCAP[®] FEIA is a newer, nonradioactive technology with minimal interference from non-specific binding to total IgE versus allergen-specific IgE.

A nasal smear can be examined for the presence of eosinophils to screen for allergic conditions. Either a single smear or smears of nasal secretions

from each side of the nose should be submitted, at room temperature, for Hansel staining and evaluation. Normal findings vary by laboratory but generally, greater than 10–15% is considered eosinophilia or increased presence of eosinophils. Results may be invalid for patients already taking local or systemic corticosteroids.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate patients who refuse to submit to skin testing or who have generalized dermatitis or other dermatopathic conditions
- Monitor response to desensitization procedures
- Test for allergens when skin testing is inappropriate, such as in infants
- Test for allergens when there is a known history of allergic reaction to skin testing
- Test for specific allergic sensitivity before initiating immunotherapy or desensitization shots
- Test for specific allergic sensitivity when skin testing is unreliable (patients taking long-acting antihistamines may have false-negative skin test)

POTENTIAL DIAGNOSIS

Different scoring systems are used in the interpretation of RAST results.

Increased in

Related to production of IgE, the antibody that primarily responds to conditions that stimulate an allergic response

- Allergic rhinitis
- Anaphylaxis
- Asthma (exogenous)

- Atopic dermatitis
- *Echinococcus* infection
- Eczema
- Hay fever
- Hookworm infection
- Latex allergy
- Schistosomiasis
- Visceral larva migrans

Decreased in

- Asthma (endogenous)
- Pregnancy
- Radiation therapy

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Recent radioactive scans or radiation within 1 wk of the test can interfere with test results when radioimmunoassay is the test method.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of causal factors related to allergic reaction.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and

explain that there may be some discomfort during the venipuncture.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Inform the laboratory of the specific allergen group to be tested. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding and hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Should be given to diet if food allergies are

present. Lifestyle adjustments may be necessary depending on the specific allergens identified.

- ▶ Recognize anxiety related to test results. Administer allergy treatment if ordered. As appropriate, educate the patient in the proper technique for administering his or her own treatments as well as safe handling and maintenance of treatment materials. Treatments may include eye drops, inhalers, nasal sprays, oral medications, or shots. Remind the patient of the importance of avoiding triggers and of being in compliance with the recommended therapy, even if signs and symptoms disappear.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include arterial/alveolar oxygen ratio, blood gases, CBC, eosinophil count, fecal analysis, hypersensitivity pneumonitis, IgE, and PFT.
- ▶ See the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Alveolar/Arterial Gradient and Arterial/Alveolar Oxygen Ratio

SYNONYM/ACRONYM: Alveolar-arterial difference, A/a gradient, a/A ratio.

COMMON USE: To assist in assessing oxygen delivery and diagnosing causes of hypoxemia such as pulmonary edema, acute respiratory distress syndrome, and pulmonary fibrosis.

SPECIMEN: Arterial blood (1 mL) collected in a heparinized syringe. Specimen should be transported tightly capped and in an ice slurry.

NORMAL FINDINGS: (Method: Selective electrodes that measure PO_2 and PCO_2)

Alveolar/arterial gradient	Less than 10 mm Hg at rest (room air)
	20–30 mm Hg at maximum exercise activity (room air)
Arterial/alveolar oxygen ratio	Greater than 0.75 (75%)

This procedure is contraindicated for

Arterial puncture in any of the following circumstances:

-  Inadequate circulation **as evidenced by an abnormal (negative) Allen test or the absence of a radial artery pulse**
-  Significant or uncontrolled bleeding disorder **as the procedure may cause excessive bleeding**; caution should be used when performing an arterial puncture on patients receiving anticoagulant therapy or thrombolytic medications
-  Infection at the puncture site **carries the potential for introducing bacteria from the skin surface into the blood stream**
-  Congenital or acquired abnormalities of the skin or blood vessels in the area of the anticipated puncture site such

as arteriovenous fistulas, burns, tumors, vascular grafts

POTENTIAL DIAGNOSIS

Increased in

- Acute respiratory distress syndrome (ARDS) **(related to thickened edematous alveoli)**
- Atelectasis **(related to mixing oxygenated and unoxygenated blood)**
- Arterial-venous shunts **(related to mixing oxygenated and unoxygenated blood)**
- Bronchospasm **(related to decrease in the diameter of the airway)**
- Chronic obstructive pulmonary disease **(related to decrease in the elasticity of lung tissue)**
- Congenital cardiac septal defects **(related to mixing oxygenated and unoxygenated blood)**
- Underventilated alveoli **(related to mucus plugs)**
- Pneumothorax **(related to collapsed lung, shunted air, and subsequent decrease in arterial oxygen levels)**
- Pulmonary edema **(related to thickened edematous alveoli)**
- Pulmonary embolus **(related to obstruction of blood flow to alveoli)**
- Pulmonary fibrosis **(related to thickened edematous alveoli)**

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Alzheimer's Disease Markers

SYNONYM/ACRONYM: CSF tau protein and β -amyloid-42, AD, APP, PS-1, PS-2, Apo E4.

COMMON USE: To assist in diagnosing Alzheimer's disease and monitoring the effectiveness of therapy.

SPECIMEN: Cerebrospinal fluid (CSF) (2 mL) collected in a plain plastic conical tube for tau protein and β -amyloid-42; whole blood from one full lavender-top (EDTA) tube for apolipoprotein E4 (ApoE4) genotyping, β -amyloid precursor protein, presenilin 1, and presenilin 2.

NORMAL FINDINGS: (Method: Enzyme-linked immunosorbent assay) Simultaneous tau protein and β -amyloid-42 measurements in CSF are used in conjunction with detection of apolipoprotein E4 alleles (restriction fragment length polymorphism) and identification of mutations in the β -amyloid precursor protein (APP), presenilin 1 (PS-1) and presenilin 2 (PS-2) genes (polymerase chain reaction and DNA sequencing) as biochemical and genetic markers of Alzheimer's disease (AD). Scientific studies indicate that a combination of elevated tau protein and decreased β -amyloid-42 protein levels are consistent with the presence of AD. The testing laboratory should be consulted for interpretation of results.

DESCRIPTION: AD is the most common cause of dementia in the elderly population. AD is a disorder of the central nervous system (CNS) that results in progressive and profound memory loss followed by loss of cognitive abilities and death. It may follow years of progressive formation of β -amyloid plaques and brain tangles, or it may appear as an early-onset form of the disease. Two recognized pathologic features of AD are neurofibrillary tangles and amyloid plaques found in the brain. Abnormal amounts of the phosphorylated microtubule-associated tau protein are the main component of the classic neurofibrillary tangles found in patients with AD. Tau protein concentration is believed to

reflect the number of neurofibrillary tangles and may be an indication of the severity of the disease. β -Amyloid-42 is a free-floating protein normally present in CSF. It is believed to accumulate in the CNS of patients with AD, causing the formation of amyloid plaques on brain tissue. The result is that these patients have lower CSF values than age-matched healthy control participants. The study of genetic markers of AD has led to an association between an inherited autosomal dominant mutation in the APP, PS-1, and PS-2 genes and overproduction of amyloid proteins. Mutations in these genes are believed to be responsible for some cases of early-onset AD. An association also exists between a gene that codes

for the production of ApoE4 and development of late-onset AD. Diagnosis of AD includes a thorough physical examination, a complete medical history, neurological examination, tests of mental status, blood tests, and brain imaging procedures.

This procedure is contraindicated for

- ◆ Patients with infection present at the needle insertion site.
- ◆ Patients with degenerative joint disease or coagulation defects.
- ◆ Patients who are uncooperative during the procedure.
- ◆ Patients with increased intracranial pressure **because overly rapid removal of CSF can result in herniation.**

INDICATIONS

- Assist in establishing a diagnosis of AD

POTENTIAL DIAGNOSIS

Increased in

Tau protein is increased in AD. Presence of ApoE4 alleles is a genetic risk factor for AD. Identification of mutations in the APP, PS-1, and PS-2 genes is associated with forms of AD.

Decreased in

βAmyloid-42 is decreased in up to 50% of healthy control participants.

- AD (related to accumulation in the brain with a corresponding decrease in CSF)
- Creutzfeldt-Jakob disease

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Some patients with AD may have normal levels of tau protein because of an insufficient number of neurofibrillary tangles.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ◆ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ◆ **Patient Teaching:** Inform the patient this test can assist in diagnosing AD and/or evaluating the effectiveness of medication used to treat AD.
- ◆ Obtain a history of the patient's complaints, including a list of known allergies, especially allergies or sensitivities to latex or anesthetics.
- ◆ Obtain a history of the patient's neurological system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ◆ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ◆ Review the procedure with the patient. Inform the patient that the procedure will be performed by a health-care provider (HCP) trained to perform the procedure and takes approximately 20 min. Address concerns about pain and explain that there may be some discomfort during the lumbar puncture. Inform the patient that a stinging sensation may be felt as the local anesthetic is injected. Instruct the patient to report any pain or other sensations that may require repositioning of the spinal needle.
- ◆ Inform the patient that the position required for the lumbar puncture may be awkward but that someone will assist. Stress the importance of

remaining still and breathing normally throughout the procedure.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Headache is a common minor complication experienced after lumbar puncture and is caused by leakage of the spinal fluid from around the puncture site. On a rare occasion the headache may require treatment with an epidural blood patch in which an anesthesiologist or pain management specialist injects a small amount of the patient's blood in the epidural space of the puncture site. The blood patch forms a clot and seals the puncture site to prevent further leakage of CSF and provides relief within 30 minutes. Other complications include lower back pain after the procedure, bleeding near the puncture site, or brain stem herniation, due to increased intracranial pressure.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

▶ Record baseline vital signs, and assess neurological status. Protocols may vary among facilities.

- ▶ To perform a lumbar puncture, position the patient in the knee-chest position at the side of the bed. Provide pillows to support the spine or for the patient to grasp. The sitting position is an alternative. In this position, the patient must bend the neck and chest to the knees.
- ▶ Prepare the site (usually between L3 and L4 or L4 and L5) with povidone-iodine, and drape the area.
- ▶ Inject a local anesthetic. Using sterile technique, the HCP inserts the spinal needle through the spinous processes of the vertebrae and into the subarachnoid space. Needle size has been shown to play a significant role in predictable incidence of post-puncture headache. However, the smaller the bevel, the more time is required to collect a sufficient volume of fluid; usually a 22-g needle is used. The stylet is removed. CSF drips from the needle if it is properly placed.
- ▶ Attach the stopcock and manometer, and measure initial CSF pressure. Normal pressure for an adult in the lateral recumbent position is 60–200 mm H₂O, and 10–100 mm H₂O for children less than 8 yr. These values depend on the body position and are different in a horizontal or sitting position. CSF pressure may be elevated if the patient is anxious, holding his or her breath, tensing muscles, or if the patient's knees are flexed too firmly against the abdomen. CSF pressure may be significantly elevated in patients with intracranial tumors or space occupying pockets of infection as seen in meningitis.
- ▶ If the initial pressure is elevated, the HCP may perform Queckenstedt's test. To perform this test, apply pressure to the jugular vein for about 10 sec. CSF pressure usually rises in response to the occlusion, then rapidly returns to normal within

10 sec after the pressure is released. Sluggish response may indicate CSF obstruction.

- ▶ Obtain four (or five) vials of fluid, according to the HCP's request, in separate tubes (1 to 3 mL in each), and label them numerically (1 to 4 or 5) in the order in which they were filled. Take a final pressure reading, and remove the needle. Clean the puncture site with an antiseptic solution, and apply direct pressure with dry gauze to stop bleeding or CSF leakage. Observe/assess puncture site for bleeding, CSF leakage, or hematoma formation, and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Monitor vital signs and neurologic status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered after lumbar puncture. Take the temperature every 4 hr for 24 hr. Compare with baseline values. Protocols may vary among facilities.
- ▶ Administer fluids if permitted, especially fluids containing caffeine, to replace lost CSF and help prevent or relieve headache, which is a side effect of lumbar puncture. Advise the patient that headache may begin within a few hours up to 2 days after the procedure and may be associated with dizziness, nausea, and vomiting. The length of time for the headache to resolve varies considerably.
- ▶ Observe/assess the puncture site for leakage, and frequently monitor body signs, such as temperature and blood pressure.

- ▶ Position the patient flat, either on the back or abdomen, although some HCPs allow 30 degrees of elevation. Maintain this position for 8 hr. Changing position is acceptable as long as the body remains horizontal.
- ▶ Observe/assess the patient for neurological changes, such as altered level of consciousness, change in pupils, reports of tingling or numbness, and irritability.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient and family members regarding access to counseling and other supportive services. Provide contact information, if desired, for the Alzheimer's Association (www.alz.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CT brain, evoked brain potentials, MRI brain, and FDG-PET scan.
- ▶ See the Musculoskeletal System table at the end of the book for related tests by body system.

Amino Acid Screen, Blood

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing congenital metabolic disorders in infants, typically homocystinuria, maple syrup urine disease, phenylketonuria (PKU), tyrosinuria, and unexplained mental retardation.

SPECIMEN: Plasma (1 mL) collected in a green-top (heparin) tube.

NORMAL FINDINGS: (Method: Liquid chromatography/mass spectrometry) There are numerous amino acids. Values vary, and the testing laboratory should be consulted for corresponding ranges.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Increased amino acid accumulation (total amino acids) occurs when a specific enzyme deficiency prevents its catabolism, with liver disease, or when there is impaired clearance by the kidneys:

- Aminoacidopathies (usually related to an inherited disorder; specific amino acids are implicated)
- Burns (related to increased protein turnover)
- Diabetes (related to gluconeogenesis, where protein is broken down as a means to generate glucose)
- Fructose intolerance (related to hereditary enzyme deficiency)
- Malabsorption (related to lack of transport and opportunity for catabolism)
- Renal failure (acute or chronic) (related to impaired clearance)
- Reyes syndrome (related to liver damage)
- Severe liver damage (related to decreased production of amino acids by the liver)
- Shock (related to increased protein turnover from tissue

death and decreased deamination due to impaired liver function)

Decreased in

Decreased (total amino acids) in conditions that result in increased renal excretion or insufficient protein intake or synthesis:

- Adrenocortical hyperfunction (related to excess cortisol, which assists in conversion of amino acids into glucose)
- Carcinoid syndrome (related to increased consumption of amino acids, especially tryptophan, to form serotonin)
- Fever (related to increased consumption)
- Glomerulonephritis (related to increased renal excretion)
- Hartnup's disease (related to increased renal excretion)
- Huntington's chorea (related to increased consumption due to muscle tremors; possible insufficient intake)
- Malnutrition (related to insufficient intake)
- Nephrotic syndrome (related to increased renal excretion)
- Pancreatitis (acute) (related to increased consumption as part of the inflammatory process and increased ureagenesis)

- Polycystic kidney disease (*related to increased renal excretion*)
- Rheumatoid arthritis (*related to insufficient*

intake evidenced by lack of appetite)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Amino Acid Screen, Urine

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing congenital metabolic disorders in infants, typically homocystinuria, maple syrup urine disease, phenylketonuria (PKU), tyrosinuria, and unexplained mental retardation.

SPECIMEN: Urine (10 mL) from a random or timed specimen collected in a clean plastic collection container with hydrochloric acid as a preservative.

NORMAL FINDINGS: (Method: Chromatography) There are numerous amino acids. Values vary, and the testing laboratory should be consulted for corresponding ranges.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Increased amino acid accumulation (total amino acids) occurs when a specific enzyme deficiency prevents its catabolism or when there is impaired clearance by the kidneys:

- Primary causes (*inherited*):
 - Aminoaciduria (specific)
 - Cystinosis (*may be masked because of decreased glomerular filtration rate, so values may be in normal range*)
 - Fanconi's syndrome
 - Fructose intolerance
 - Galactosemia
 - Hartnup's disease
 - Lactose intolerance
 - Lowe's syndrome
 - Maple syrup urine disease
 - Tyrosinemia type I
 - Tyrosinosis
 - Wilson's disease

- Secondary causes (*noninherited*):

- Acute leukemia
- Chronic renal failure (*reduced glomerular filtration rate*)
- Chronic renal failure
- Diabetic ketosis
- Epilepsy (*transient increase related to disturbed renal function during grand mal seizure*)
- Folic acid deficiency
- Hyperparathyroidism
- Liver necrosis and cirrhosis
- Multiple myeloma
- Muscular dystrophy (progressive)
- Osteomalacia (*secondary to parathyroid hormone excess*)
- Pernicious anemia
- Thalassemia major
- Vitamin deficiency (*B, C, and D; vitamin D—deficiency rickets, vitamin D—resistant rickets*)
- Viral hepatitis (*related to the degree of hepatic involvement*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

δ-Aminolevulinic Acid

SYNONYM/ACRONYM: δ-ALA.

COMMON USE: To assist in diagnosing lead poisoning in children, or porphyria, a disorder that disrupts heme synthesis, primarily affecting the liver.

SPECIMEN: Urine (25 mL) from a timed specimen collected in a dark plastic container with glacial acetic acid as a preservative.

NORMAL FINDINGS: (Method: Spectrophotometry)

Conventional Units	SI Units (Conventional Units × 7.626)
1.5–7.5 mg/24 hr	11.4–57.2 micromol/24 hr

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Related to inhibition of the enzymes involved in porphyrin synthesis; results in accumulation of δ-ALA and is evidenced by exposure to medications, toxins, diet, or infection that can precipitate an attack

- Acute porphyrias
- Aminolevulinic acid dehydrase deficiency (*related to the inability to convert δ-ALA to porphobilinogen, leading to accumulation of δ-ALA*)
- Hereditary tyrosinemia
- Lead poisoning

Decreased in: N/A

CRITICAL FINDINGS

Conventional Units	SI Units (Conventional Units × 7.62)
Greater than 20 mg/24 hr	Greater than 152.4 micromol/24 hr

Note and immediately report to the health-care provider (HCP) abnormal results and associated symptoms. It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities. Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management. Signs and symptoms of an acute porphyria attack include pain (commonly in the abdomen, arms, and legs), nausea, vomiting, muscle weakness, rapid pulse, and high blood pressure. Possible interventions include medication for pain, nausea, and vomiting and, if indicated, respiratory support. Initial treatment following a moderate to severe attack may include identification and cessation of harmful drugs the patient may be taking, IV infusion of carbohydrates, and IV heme therapy (Panhematin) if indicated by markedly elevated urine δ-ALA and porphyrins.

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Ammonia

SYNONYM/ACRONYM: NH₃.

COMMON USE: To assist in diagnosing liver disease such as hepatitis and cirrhosis and evaluating the effectiveness of treatment modalities. Specifically used to assist in diagnosing infant Reye's syndrome.

SPECIMEN: Plasma (1 mL) collected in completely filled lavender- (EDTA) or green-top (Na or Li heparin) tube. Specimen should be transported tightly capped and in an ice slurry.

NORMAL FINDINGS: (Method: Enzymatic)

Age	Conventional Units	SI Units (Conventional Units × 0.587)
Newborn	170–340 mcg/dL	100–200 micromol/L
10 d–24 mo	68–136 mcg/dL	40–80 micromol/L
25 mo–Adult	19–60 mcg/dL	11–35 micromol/L

DESCRIPTION: Blood ammonia (NH₃) comes from two sources: deamination of amino acids during protein metabolism and degradation of proteins by colon bacteria. The liver converts ammonia in the portal blood to urea, which is excreted by the kidneys. When liver function is severely compromised, especially in situations in which decreased hepatocellular function is combined with impaired portal blood flow, ammonia levels rise. Congenital enzyme defects that prevent the breakdown of ammonia or conditions that affect the ability of the kidneys to excrete ammonia can also result in increased blood levels. Ammonia is potentially toxic to the central nervous system and may result in encephalopathy or coma if toxic levels are reached.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate advanced liver disease or other disorders associated with altered serum ammonia levels
- Identify impending hepatic encephalopathy with known liver disease
- Monitor the effectiveness of treatment for hepatic encephalopathy, indicated by declining levels
- Monitor patients receiving hyperalimentation therapy

POTENTIAL DIAGNOSIS

Increased in

- Gastrointestinal hemorrhage (*related to decreased blood volume, which prevents ammonia from reaching the liver to be metabolized*)
- Genitourinary tract infection with distention and stasis (*related to*

decreased renal excretion; levels accumulate in the blood)

- Hepatic coma (*related to insufficient functioning liver cells to metabolize ammonia; levels accumulate in the blood*)
- Inborn enzyme deficiency (*evidenced by inability to metabolize ammonia*)
- Liver failure, late cirrhosis (*related to insufficient functioning liver cells to metabolize ammonia*)
- Reye's syndrome (*related to insufficient functioning liver cells to metabolize ammonia*)
- Total parenteral nutrition (*related to ammonia generated from protein metabolism*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase ammonia levels include asparaginase, chlorthiazide, chlorthalidone,

fibrin hydrolysate, furosemide, hydroflumethiazide, isoniazid, levoglutamide, mercurial diuretics, oral resins, thiazides, and valproic acid.

- Drugs/organisms that may decrease ammonia levels include diphenhydramine, kanamycin, monoamine oxidase inhibitors, neomycin, tetracycline, and *Lactobacillus acidophilus*.
- Hemolysis falsely increases ammonia levels because intracellular ammonia levels are three times higher than plasma.
- Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. The specimen should be collected on ice; the collection tube should be filled completely and then kept tightly stoppered. Ammonia increases rapidly in the collected specimen, so analysis should be performed within 20 min of collection.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Confusion (<i>Related to an alteration in fluid and electrolytes, hepatic disease and encephalopathy; acute alcohol consumption; hepatic metabolic insufficiency</i>)	Disorganized thinking, restless, irritable, altered concentration and attention span, changeable mental function over the day, hallucinations; altered attention span; unable to follow directions; disoriented to person, place, time, and purpose; inappropriate affect	Treat the medical condition; correlate confusion with the need to reverse altered electrolytes; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or the appropriate use of restraints; consider pharmacological interventions; track accurate intake and output to assess fluid status; monitor blood ammonia level; determine last alcohol use; assess

(table continues on page 52)

Problem	Signs & Symptoms	Interventions
Nutrition (<i>Related to excess alcohol intake; insufficient eating habits; altered liver function</i>)	Known inadequate caloric intake; weight loss; muscle wasting in arms and legs; stool that is pale or grey colored; skin that is flaky with loss of elasticity	for symptoms of hepatic encephalopathy such as confusion, sleep disturbances, incoherence; protect the patient from physical harm; administer lactose as prescribed Document food intake with possible calorie count; assess barriers to eating; consider using a food diary; monitor continued alcohol use as it is a barrier to adequate protein nutrition; monitor glucose levels; monitor daily weight; perform dietary consult with assessment of cultural food selections
Skin (<i>Related to jaundice and elevated bilirubin levels; excessive scratching</i>)	Jaundiced skin and sclera; dry skin; itching skin; damage to skin associated with scratching	Application of lotion to keep the skin moisturized; avoid alkaline soaps; discourage scratching; apply mittens if patient is not able to follow direction to avoid scratching; administer antihistamines as ordered
Bleeding (<i>Related to altered clotting factors; portal hypertension; esophageal bleeding</i>)	Altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; capillary refill greater than 3 sec; cool extremities	Increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; administer stool softeners as needed; encourage intake of foods rich in vitamin K; avoid foods that may irritate esophagus

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with the evaluation of liver function related to processing protein waste. May be used to assist in diagnosis of Reye's syndrome in infants.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal, genitourinary, and hepatobiliary systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess the venipuncture site for bleeding or hematoma formation and secure the gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP),

who will discuss the results with the patient.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure. Recognize anxiety related to test results, and carefully observe the cirrhotic patient for the development of ascites, in which case fluid and electrolyte balance require strict attention. Dietary and fluid restrictions may be required; diuretics may be ordered. The patient should be frequently monitored for weight gain, intake and output, and abdominal girth. The alcoholic patient should be encouraged to avoid alcohol and also to seek appropriate counseling for substance abuse.
- ▶ **Nutritional Considerations:** Increased ammonia levels may be associated with liver disease. Dietary recommendations may be indicated, depending on the severity of the condition. A low-protein diet may be in order if the patient's liver has lost the ability to process the end products of protein metabolism. A diet of soft foods may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs) rather than complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which would require additional bile to emulsify them so that they could be used.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

- Teach the patient that small frequent meals throughout the day can increase overall caloric intake and improve nutritional status.
- Teach the patient that scratching can damage the skin and precipitate an infection.

Expected Patient Outcomes:

Knowledge

- Discusses that adherence to eating several small meals can improve caloric intake
- Associates compliance with taking lactulose with decreased blood ammonia level to help prevent hepatic encephalopathy

Skills

- Modifies the diet and selects foods that are appropriate for the degree of liver disease (high protein and high carbohydrate can support nutrition until liver disease prohibits these food selections)
- Accurately self-administers lactulose as prescribed to reduce absorption of ammonia

Attitude

- Resolves to participate in counseling for alcohol abuse
- Follows the recommendations of the physician and family members in supporting positive health decisions

RELATED MONOGRAPHS:

- Related tests include ALT, albumin, analgesic, anti-inflammatory, and antipyretic drugs (acetaminophen and acetylsalicylic acid), anion gap, AST, bilirubin, biopsy liver, blood gases, BUN, blood calcium, CT biliary tract and liver, CT pelvis, cystometry, cystoscopy, EGD, electrolytes, GI blood loss scan, glucose, IVP, MRI pelvis, ketones, lactic acid, Meckle's scan, osmolality, protein, PT/INR, uric acid, and US pelvis.
- See the Gastrointestinal, Genitourinary, and Hepatobiliary systems tables at the end of the book for related tests by body system.

Amniotic Fluid Analysis and L/S Ratio

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in identification of fetal gender, genetic disorders such as hemophilia and sickle cell anemia, chromosomal disorders such as Down syndrome, anatomical abnormalities such as spina bifida, and hereditary metabolic disorders such as cystic fibrosis. To assess for preterm infant fetal lung maturity to assist in evaluating for potential diagnosis of respiratory distress syndrome (RDS).

SPECIMEN: Amniotic fluid (10 to 20 mL) collected in a clean amber glass or plastic container.

NORMAL FINDINGS: (Method: Macroscopic observation of fluid for color and appearance, immunochemiluminometric assay [ICMA] for α_1 -fetoprotein, electrophoresis for acetylcholinesterase, spectrophotometry for creatinine and bilirubin, chromatography for lecithin/sphingomyelin [L/S] ratio and phosphatidylglycerol, tissue culture for chromosome analysis, dipstick for leukocyte esterase, and automated cell counter for white blood cell count and lamellar bodies)

Test	Reference Value
Color	Colorless to pale yellow
Appearance	Clear
α_1 -Fetoprotein	Less than 2 MoM*
Acetylcholinesterase	Absent
Creatinine	1.8–4 mg/dL at term
Bilirubin	Less than 0.075 mg/dL in early pregnancy Less than 0.025 mg/dL at term
Bilirubin ΔA_{450}	Less than 0.048 ΔOD in early pregnancy Less than 0.02 ΔOD at term
L/S ratio	
Mature (nondiabetic)	Greater than 2:1 in the presence of phosphatidyl glycerol
Borderline	1.5 to 1.9:1
Immature	Less than 1.5:1
Phosphatidylglycerol	Present at term
Chromosome analysis	Normal karyotype
White blood cell count	None seen
Leukocyte esterase	Negative
Lamellar bodies	Findings and interpretive ranges vary depending on the type of instrument used

*MoM = Multiples of the median.

DESCRIPTION: Amniotic fluid is formed in the membranous sac that surrounds the fetus. The total volume of fluid at term is 500 to 2,500 mL. In amniocentesis, fluid is obtained by ultrasound-guided needle aspiration from the amniotic sac. This procedure is generally performed between 14 and 16 weeks' gestation for accurate interpretation of test results, but it also can be done between 26 and 35 weeks' gestation if fetal distress is suspected. Amniotic fluid is tested to identify genetic and neural tube defects, hemolytic diseases of the newborn, fetal infection, fetal renal malfunction, or maturity of the fetal lungs. Examples of genetic defects that are commonly tested for and can be identified from a sample of amniotic fluid include sickle cell anemia, cystic fibrosis, and inborn

errors of metabolism. Several rapid tests are also used to differentiate amniotic fluid from other body fluids in a vaginal specimen when premature rupture of membranes (PROM) is suspected. A vaginal swab obtained from the posterior vaginal pool can be used to perform a rapid, waived procedure to aid in the assessment of PROM. Nitrazine paper impregnated with an indicator dye will produce a color change indicative of vaginal pH. Normal vaginal pH is acidic (4.5 to 6) and the color of the paper will not change. Amniotic fluid has an alkaline pH (7.1 to 7.3) and the paper will turn a blue color. False-positive results occur in the presence of semen, blood, alkaline urine, vaginal infection, or if the patient is receiving antibiotics. The amniotic fluid crystallization

or Fern test is based on the observation of a fern pattern when amniotic fluid is placed on a glass slide and allowed to air dry. The fern pattern is due to the protein and sodium chloride content of the amniotic fluid. False-positive results occur in the presence of blood urine or cervical mucus. Both of these tests can produce false-negative results if only a small amount of fluid is leaked. The reliability of results is also significantly diminished with the passage of time (greater than 24 hr). AmniSure is an immunoassay that can be performed on a vaginal swab sample. It is a rapid test that detects placental alpha microglobulin-1 protein (PAMG-1), which is found in high concentrations in amniotic fluid. AmniSure does not demonstrate the high frequency of false-positive and false-negative results inherent with the pH and fern tests.

Respiratory distress syndrome (RDS) is the most common problem encountered in the care of premature infants. RDS, also called hyaline membrane disease, results from a deficiency of phospholipid lung surfactants. The phospholipids in surfactant are produced by specialized alveolar cells and stored in granular lamellar bodies in the lung. In normally developed lungs, surfactant coats the surface of the alveoli. Surfactant reduces the surface tension of the alveolar wall during breathing. When there is an insufficient quantity of surfactant, the alveoli are unable to expand normally and gas exchange is inhibited. Amniocentesis, a procedure by which fluid is removed from the amniotic sac, is used to assess fetal lung maturity.

Lecithin is the primary surfactant phospholipid, and it is a stabilizing factor for the alveoli. It is produced at a low but constant rate until the 35th wk of gestation, after which its production sharply increases. Sphingomyelin, another phospholipid component of surfactant, is also produced at a constant rate after the 26th wk of gestation. Before the 35th wk, the lecithin/sphingomyelin (L/S) ratio is usually less than 1.6:1. The ratio increases to 2 or greater when the rate of lecithin production increases after the 35th wk of gestation. Other phospholipids, such as phosphatidyl glycerol (PG) and phosphatidyl inositol (PI), increase over time in amniotic fluid as well. The presence of PG indicates that the fetus is within 2 to 6 wk of lung maturity (i.e., at full term). Simultaneous measurement of PG with the L/S ratio improves diagnostic accuracy. Production of phospholipid surfactant is delayed in diabetic mothers. Therefore, caution must be used when interpreting the results obtained from a diabetic patient, and a higher ratio is expected to predict maturity.

This procedure is contraindicated for

-  Women with a history of premature labor, incompetent cervix, or in the presence of placenta previa or abruptio placentae. There is some risk to having an amniocentesis performed, and this should be weighed against the need to obtain the desired diagnostic information. A small percentage (0.5%) of patients have experienced complications including premature rupture of the membranes, premature labor, spontaneous abortion, and stillbirth.

INDICATIONS

- Assist in the diagnosis of (in utero) metabolic disorders, such as cystic fibrosis, or errors of lipid, carbohydrate, or amino acid metabolism
- Assist in the evaluation of fetal lung maturity when preterm delivery is being considered
- Detect infection secondary to ruptured membranes
- Detect fetal ventral wall defects
- Determine the optimal time for obstetric intervention in cases of threatened fetal survival caused by stresses related to maternal diabetes, toxemia, hemolytic diseases of the newborn, or postmaturity
- Determine fetal gender when the mother is a known carrier of a sex-linked abnormal gene that could be transmitted to male offspring, such as hemophilia or Duchenne's muscular dystrophy
- Determine the presence of fetal distress in late-stage pregnancy
- Evaluate fetus in families with a history of genetic disorders, such as Down syndrome, Tay-Sachs disease, chromosome or enzyme anomalies, or inherited hemoglobinopathies
- Evaluate fetus in mothers of advanced maternal age (some of the aforementioned tests are routinely requested in mothers age 35 and older)
- Evaluate fetus in mothers with a history of miscarriage or stillbirth
- Evaluate known or suspected hemolytic disease involving the fetus in an Rh-sensitized pregnancy, indicated by rising bilirubin levels, especially after the 30th week of gestation
- Evaluate suspected neural tube defects, such as spina bifida or myelomeningocele, as indicated by elevated α_1 -fetoprotein (see monograph titled " α_1 -Fetoprotein" for information related to triple-marker testing)
- Identify fetuses at risk of developing RDS

POTENTIAL DIAGNOSIS

- Yellow, green, red, or brown fluid *indicates the presence of bilirubin, blood (fetal or maternal), or meconium, which indicate fetal distress or death, hemolytic disease, or growth retardation.*
- Elevated bilirubin levels *indicate fetal hemolytic disease or intestinal obstruction. Measurement of bilirubin is not usually performed before 20 to 24 weeks' gestation because no action can be taken before then. The severity of hemolytic disease is graded by optical density (OD) zones: A value of 0.28 to 0.46 OD at 28 to 31 weeks' gestation indicates mild hemolytic disease, which probably will not affect the fetus; 0.47 to 0.9 OD indicates a moderate effect on the fetus; and 0.91 to 1 OD indicates a significant effect on the fetus. A trend of increasing values with serial measurements may indicate the need for intrauterine transfusion or early delivery, depending on the fetal age. After 32 to 33 weeks' gestation, early delivery is preferred over intrauterine transfusion, because early delivery is more effective in providing the required care to the neonate.*
- Creatinine concentration greater than 2 mg/dL *indicates fetal maturity (at 36 to 37 wk) if maternal creatinine is also within the expected range. This value should be interpreted in conjunction with other parameters evaluated in amniotic fluid and especially with the L/S ratio, because normal lung development depends on normal kidney development.*
- An L/S ratio less than 2:1 and absence of phosphatidylglycerol at

term *indicate fetal lung immaturity and possible respiratory distress syndrome. Other conditions that decrease production of surfactants include advanced maternal age, multiple gestation, and polyhydramnios. Conditions that may increase production of surfactant include hypertension, intrauterine growth retardation, malnutrition, maternal diabetes, placenta previa, placental infarction, and premature rupture of the membranes. The expected L/S ratio for the fetus of an insulin-dependent diabetic mother is higher (3.5:1).*

- *Lamellar bodies are specialized alveolar cells in which lung surfactant is stored. They are approximately the size of platelets. Their presence in sufficient quantities is an indicator of fetal lung maturity.*
- *Elevated α_1 -fetoprotein levels and presence of acetylcholinesterase indicate a neural tube defect (see monograph titled “ α_1 -Fetoprotein”). Elevation of acetylcholinesterase is also indicative of ventral wall defects.*
- *Abnormal karyotype indicates genetic abnormality (e.g., Tay-Sachs disease, mental retardation, chromosome or enzyme anomalies, and inherited hemoglobinopathies). (See monograph titled “Chromosome Analysis, Blood.”)*
- *Elevated white blood cell count and positive leukocyte esterase are indicators of infection.*

CRITICAL FINDINGS: An L/S ratio less than 1.5:1 is predictive of RDS at the time of delivery.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Infants known to be at risk for RDS can be treated with surfactant by intratracheal administration at birth.

INTERFERING FACTORS

- Bilirubin may be falsely elevated if maternal hemoglobin or meconium is present in the sample; fetal acidosis may also lead to falsely elevated bilirubin levels.
- Bilirubin may be falsely decreased if the sample is exposed to light or if amniotic fluid volume is excessive.
- Maternal serum creatinine should be measured simultaneously for comparison with amniotic fluid creatinine for proper interpretation. Even in circumstances in which the maternal serum value is normal, the results of the amniotic fluid creatinine may be misleading. A high fluid creatinine value in the

fetus of a diabetic mother may reflect the increased muscle mass of a larger fetus. If the fetus is big, the creatinine may be high, and the fetus may still have immature kidneys.

- Contamination of the sample with blood or meconium or complications in pregnancy may yield inaccurate L/S ratios; fetal blood falsely elevates the L/S ratio.

- α_1 -Fetoprotein and acetylcholinesterase may be falsely elevated if the sample is contaminated with fetal blood.
- Karyotyping cannot be performed under the following conditions: (1) failure to promptly deliver samples for chromosomal analysis to the laboratory performing the test or (2) improper incubation of the sample, which causes cell death.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fear (<i>Related to fetal imperfections secondary to developmental abnormality</i>)	Verbalization of fear; restlessness; increased tension; continuous questioning; increased blood pressure, heart rate, respiratory rate	Evaluate verbal and nonverbal indicators of fear; assess for the cause of fear; acknowledge the patient's awareness of fear; explain all procedures with simple age and culturally appropriate language; administer proscribed mild tranquilizer; maintain a confident assured professional manner in all patient interactions; address concerns regarding care of disabled child; recommend support group and provide contact information
Spirituality (<i>Related to anxiety associated with fetal developmental abnormality; unexpected life changes</i>)	Anger; stated feelings of lack of peace or serenity; stated feelings of alienation from others; stated feelings of hopelessness; request to meet with spiritual leader	Obtain a history of the patient's religious affiliation; identify the patient's willingness to meet with spiritual leader; encourage verbalization of concerns, feelings of fear and loneliness; acknowledge and support religious practices; accommodate a display of religious objects; facilitate communication between the patient, family, and religious leader

(table continues on page 60)

Problem	Signs & Symptoms	Interventions
Knowledge <i>(Related to insufficient information associated with diagnosed developmental abnormality; lack of familiarity or understanding with disease and treatment)</i>	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management; stating inaccurate information; frustration; confusion	Identify the primary learners and provide specific information that is culturally appropriate and to the correct literacy level; assess for the willingness and ability to learn; identify the patient's priority for learning; identify and dispel any misconceptions associated with the developmental disability; identify the patient's learning style; provide a quiet atmosphere for learning; allow the parents to be self-directed in their learning; provide sufficient time for questions and follow up; refer to a support group and social services as appropriate

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the parent this procedure/test can assist in providing a sample of fluid that will allow for evaluation of fetal well-being.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's reproductive system, previous pregnancies, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Include any family history of genetic disorders such as cystic fibrosis, Duchenne's muscular dystrophy, hemophilia, sickle cell disease, Tay-Sachs disease, thalassemia, and trisomy 21. Obtain maternal Rh type. If Rh-negative, check for prior sensitization. A standard dose of Rh₁(D) immune globulin RhoGAM IM or Rhophylac IM or IV is indicated after amniocentesis; repeat doses should be considered if repeated amniocentesis is performed.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Record the date of the last menstrual period and determine the pregnancy weeks' gestation and expected delivery date.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Warn the patient that normal results do not guarantee a normal fetus. Assure the patient that precautions to avoid injury to the fetus will be taken by localizing the fetus with ultrasound. Address concerns about pain and explain that during the transabdominal procedure, any discomfort associated with a needle biopsy will be minimized with local anesthetics. If the patient is less than 20 weeks' gestation, instruct her to drink extra fluids 1 hr before the test and to refrain from urination. The full bladder assists in raising the uterus up and out of the way to provide better visualization during the ultrasound procedure. Patients who are at 20 weeks' gestation or beyond do not need to drink extra fluids and should void before the test, because an empty bladder is less likely to be accidentally punctured during specimen collection.

Encourage relaxation and controlled breathing during the procedure to aid in reducing any mild discomfort. Inform the patient that specimen collection is performed by a health-care provider (HCP) specializing in this procedure and usually takes approximately 20 to 30 min to complete.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Hemorrhage from highly vascular tissue or infection following amniocentesis.

Instruct the patient to look for excessive bleeding, redness of skin, fever, or chills and to notify the HCP if these symptoms occur. An additional risk with amniocentesis is maternal Rh sensitization by fetal RBCs in the case of an Rh-negative mother carrying an Rh-positive fetus. RhIG (Rh immune globulin) or RhoGam may be administered after amniocentesis to Rh-negative mothers to prevent formation of Rh antibodies.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Ensure that the patient has a full bladder before the procedure if gestation is 20 wk or less; have patient void before the procedure if gestation is 21 wk or more.
- ▶ Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date, time of collection, and site location.
- ▶ Have patient remove clothes below the waist. Assist the patient to a supine position on the examination table with the abdomen exposed. Drape the patient's legs, leaving the abdomen exposed. Raise her head or legs slightly to promote comfort and to

relax the abdominal muscles. If the uterus is large, place a pillow or rolled blanket under the patient's right side to prevent hypertension caused by great-vessel compression. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

- ▶ Record maternal and fetal baseline vital signs, and continue to monitor throughout the procedure. Monitor for uterine contractions. Monitor fetal vital signs using ultrasound. Protocols may vary among facilities.
- ▶ Have emergency equipment readily available.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Assess the position of the amniotic fluid, fetus, and placenta using ultrasound.
- ▶ Assemble the necessary equipment, including an amniocentesis tray with solution for skin preparation, local anesthetic, 10- or 20-mL syringe, needles of various sizes (including a 22-gauge, 5-in. spinal needle), sterile drapes, sterile gloves, and foil-covered or amber-colored specimen collection containers.
- ▶ Cleanse suprapubic area with an antiseptic solution, and protect with sterile drapes. A local anesthetic is injected. Explain that this may cause a stinging sensation.
- ▶ Insert a 22-gauge, 5-in. spinal needle through the abdominal and uterine walls. Explain that a sensation of pressure may be experienced when the needle is inserted. Explain to the patient how to use focused and controlled breathing for relaxation during the procedure.
- ▶ Apply slight pressure to the site after the fluid is collected and the needle is withdrawn. If there is no evidence of bleeding or other drainage, apply a sterile adhesive bandage to the site.

▶ Monitor the patient for complications related to the procedure (e.g., premature labor, allergic reaction, anaphylaxis).

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Compare fetal heart rate and maternal life signs (i.e., heart rate, blood pressure, pulse, and respiration) with baseline values and closely monitor every 15 min for 30 to 60 min after the amniocentesis procedure. Protocols may vary among facilities.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the amniocentesis site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the amniocentesis site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the amniocentesis site.
- ▶ Instruct the patient to expect mild cramping, leakage of small amounts of amniotic fluid, and vaginal spotting for up to 2 days following the procedure. Instruct the patient to report moderate to severe abdominal pain or cramps, change in fetal activity, increased or prolonged leaking of amniotic fluid from abdominal needle site, vaginal bleeding that is heavier than spotting, and either chills or fever.
- ▶ Instruct the patient to rest until all symptoms have disappeared before resuming normal levels of activity.
- ▶ Administer standard RhoGAM dose to maternal Rh-negative patients to prevent maternal Rh sensitization should the fetus be Rh-positive.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Encourage the family to seek appropriate counseling if concerned with pregnancy termination and to seek genetic counseling if a chromosomal

abnormality is determined. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant as well as for exploring other options (termination of pregnancy or adoption). It is also important to discuss problems the mother and father may experience (guilt, depression, anger) if fetal abnormalities are detected.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Inform the patient that it may be 2 to 4 wk before all results are available.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications.

Expected Patient Outcomes:

Knowledge

- ▶ The patient states understanding of the importance of adhering to the therapy regimen provided by the HCP.
- ▶ The patient states understanding of the significant side effects and systemic reactions associated with the prescribed medication.

Skills

- ▶ The patient accurately describes care necessary to support the health of the developmentally disabled infant.
- ▶ The patient accurately describes the lifestyle changes that will be necessary to provide care for the developmentally disabled infant.

Attitude

- ▶ The patient complies with the request to review the literature provided by a pharmacist regarding prescribed medications.

‡ The patient agrees to meet with support group in relation to diagnosed developmental disability.

RELATED MONOGRAPHS:

‡ Related tests include α_1 -fetoprotein, antibodies anticardiolipin, blood groups and antibodies, chromosome

analysis, fetal fibronectin, glucose, ketones, Kleihauer-Betke test, lupus anticoagulant antibodies, newborn screening, potassium, US biophysical profile obstetric, and UA.

‡ Refer to the Reproductive System table at the end of the book for related tests by body system.

Amylase

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosis and evaluation of the treatment modalities used for pancreatitis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Enzymatic)

Age	Conventional & SI Units
3–90 d	0–30 units/L
3–6 mo	6–40 units/L
7–11 mo	6–70 units/L
1–3 yr	11–80 units/L
4–9 yr	16–91 units/L
10–18 yr	19–76 units/L
Adult–older adult	30–110 units/L

Values may be slightly elevated in older adults due to the effects of medications and the presence of multiple chronic or acute diseases with or without muted symptoms.

DESCRIPTION: Amylase is a digestive enzyme mainly secreted by the acinar cells of the pancreas and by the parotid glands. Pancreatic amylase is secreted into the pancreatic common bile ducts and then into the duodenum where it assists in the digestion of carbohydrates by splitting starch into disaccharides. Amylase is a sensitive indicator of pancreatic acinar cell damage and

pancreatic obstruction. Newborns and children up to 2 years old have little measurable serum amylase. In the early years of life, most of this enzyme is produced by the salivary glands. Amylase can be separated into pancreatic (P_1, P_2, P_3) and salivary (S_1, S_2, S_3) isoenzymes. Isoenzyme patterns are useful in identifying the organ source. Requests for amylase isoenzymes are rare because of

the expense of the procedure and limited clinical utility of the result. Isoenzyme analysis is primarily used to assess decreasing pancreatic function in children 5 years and older who have been diagnosed with cystic fibrosis and who may be candidates for enzyme replacement. Cyst fluid amylase levels with isoenzyme analysis is useful in differentiating pancreatic neoplasms (low enzyme concentration) and pseudocysts (high enzyme concentration). Lipase is usually ordered in conjunction with amylase because lipase is more sensitive and specific to conditions affecting pancreatic function.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of early acute pancreatitis; serum amylase begins to rise within 6 to 24 hr after onset and returns to normal in 2 to 7 days
- Assist in the diagnosis of macroamylasemia, a disorder seen in alcoholism, malabsorption syndrome, and other digestive problems
- Assist in the diagnosis of pancreatic duct obstruction, which causes serum amylase levels to remain elevated
- Detect blunt trauma or inadvertent surgical trauma to the pancreas
- Differentiate between acute pancreatitis and other causes of abdominal pain that require surgery

POTENTIAL DIAGNOSIS

Increased in

Amylase is released from any damaged cell in which it is stored, so conditions that affect the pancreas and parotid glands and cause cellular destruction demonstrate elevated amylase levels.

- Acute appendicitis (*related to enzyme release from damaged pancreatic tissue*)
- Administration of some drugs (e.g., morphine) is known to increase amylase levels (*related to increased biliary tract pressure as evidenced by effect of narcotic analgesic drugs*)
- Afferent loop syndrome (*related to impaired pancreatic duct flow*)
- Aortic aneurysm (*elevated amylase levels following rupture are associated with a poor prognosis; both S and P subtypes have been identified following rupture. The causes for elevation are mixed and difficult to state as a generalization*)
- Abdominal trauma (*related to release of enzyme from damaged pancreatic tissue*)
- Alcoholism (*related to increased secretion; salivary origin most likely*)
- Biliary tract disease (*related to impaired pancreatic duct flow*)
- Burns and traumatic shock
- Carcinoma of the head of the pancreas (advanced) (*related to enzyme release from damaged pancreatic tissue*)
- Common bile duct obstruction, common bile duct stones (*related to impaired pancreatic duct flow*)
- Diabetic ketoacidosis (*related to increased secretion; salivary origin most likely*)
- Duodenal obstruction (*accumulation in the blood as evidenced by leakage from the gut*)
- Ectopic pregnancy (*related to ectopic enzyme production by the fallopian tubes*)
- Extrapancreatic tumors (especially esophagus, lung, ovary)
- Gastric resection (*accumulation in the blood as evidenced by leakage from the gut*)

- Hyperlipidemias (etiology is unclear, but there is a distinct association with amylasemia)
- Hyperparathyroidism (etiology is unclear, but there is a distinct association with amylasemia)
- Intestinal obstruction (*related to impaired pancreatic duct flow*)
- Intestinal infarction (*related to impaired pancreatic duct flow*)
- Macroamylasemia (*related to decreased ability of renal glomeruli to filter large molecules as evidenced by accumulation in the blood*)
- Mumps (*related to increased secretion from inflamed tissue; salivary origin most likely*)
- Pancreatic ascites (*related to release of pancreatic fluid into the abdomen and subsequent absorption into the circulation*)
- Pancreatic cyst and pseudocyst (*related to release of pancreatic fluid into the abdomen and subsequent absorption into the circulation*)
- Pancreatitis (*related to enzyme release from damaged pancreatic tissue*)
- Parotitis (*related to increased secretion from inflamed tissue; salivary origin most likely*)
- Perforated peptic ulcer whether the pancreas is involved or not (*related to enzyme release from damaged pancreatic tissue; involvement of the pancreas may be unnoticed upon gross examination yet be present as indicated by elevated enzyme levels*)
- Peritonitis (*accumulation in the blood as evidenced by leakage from the gut*)
- Postoperative period (*related to complications of the surgical procedure*)
- Pregnancy (*related to increased secretion; salivary origin most*

likely related to hyperemesis or hyperlipidemia induced pancreatitis related to increased estrogen levels)

- Renal disease (*related to decreased renal excretion as evidenced by accumulation in blood*)
- Some tumors of the lung and ovaries (*related to ectopic enzyme production*)
- Tumor of the pancreas or adjacent area (*related to release of enzyme from damaged pancreatic tissue*)

Decreased in

- Hepatic disease (severe) (*may be due to lack of amino acid production necessary for enzyme manufacture*)
- Pancreatectomy
- Pancreatic insufficiency
- Toxemia of pregnancy

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that may increase amylase levels include acetaminophen, aminosalicic acid, amoxapine, asparaginase, azathioprine, bethanechol, calcitriol, cholinergics, chlorthalidone, clozapine, codeine, corticosteroids, corticotropin, desipramine, dexamethasone, diazoxide, felbamate, fentanyl, fluvastatin, glucocorticoids, hydantoin derivatives, hydrochlorothiazide, hydroflumethiazide, meperidine, mercaptopurine, methacholine, methyclothiazide, metolazone, minocycline, morphine, nitrofurantoin, opium alkaloids, pegaspargase, pentazocine, potassium iodide, prednisone, procyclidine, tetracycline, thiazide diuretics, valproic acid, zalcitabine, and zidovudine.
- Drugs that may decrease amylase levels include anabolic steroids, citrates, and fluorides.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fluid volume (<i>Related to vomiting; decreased oral intake; diaphoresis; NPO with NGT; overly aggressive fluid resuscitation; compromised renal function; overly aggressive diuresis</i>)	Deficient: decreased urinary output, fatigue, and sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status. Overload: Edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values.	Daily weight with monitoring of trends; accurate intake and output; collaboration with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes as ordered
Nutrition (<i>Related to altered pancreatic function excess alcohol intake; insufficient eating habits; altered pancreatic function liver function</i>)	Known inadequate caloric intake; weight loss; muscle wasting in arms and legs; stool that is pale or grey colored; skin that is flaky with loss of elasticity	Document food intake with possible calorie count; assess barriers to eating; consider using a food diary; monitor continued alcohol use as it is a barrier to adequate protein nutrition; monitor glucose levels; check daily weight; arrange dietary consult with assessment of cultural food selections

Problem	Signs & Symptoms	Interventions
Gas exchange <i>(Related to accumulation of pleural fluid, atelectasis, ventilation perfusion mismatch; altered oxygen supply)</i>	Irregular breathing pattern, use of accessory muscles; altered chest excursion; adventitious breath sounds (crackles, rhonchi, wheezes, diminished breath sounds); copious secretions; signs of hypoxia	Monitor respiratory rate and effort based on assessment of patient condition; assess lung sounds frequently; monitor for secretions; suction as necessary; use pulse oximetry to monitor oxygen saturation; collaborate with physician to administer oxygen as needed; elevate the head of the bed 30 degrees; monitor IV fluids and avoid aggressive fluid resuscitation
Pain <i>(Related to pancreatic inflammation and surrounding tissues; excessive alcohol intake; infection)</i>	Emotional symptoms of distress; crying; agitation; facial grimace; moaning; verbalization of pain; rocking motions; irritability; disturbed sleep; diaphoresis; altered blood pressure and heart rate; nausea; vomiting; self-report of pain; upper abdominal and gastric pain after eating fatty foods or alcohol intake with acute pancreatic disease; pain may be decreased or absent in chronic pancreatic disease	Collaborate with the patient and physician to identify the best pain management modality to provide relief; refrain from activities that may aggravate pain; use the application of heat or cold to the best effect in managing the pain; monitor pain severity

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating pancreatic health and/or the effectiveness of medical treatment for pancreatitis.
- ▶ Obtain a history of the patient's complaints, including a list of known

- allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased amylase levels may be associated with gastrointestinal disease or alcoholism. Small, frequent meals work best for

patients with gastrointestinal disorders. Consideration should be given to dietary alterations in the case of gastrointestinal disorders. Usually after acute symptoms subside and bowel sounds return, patients are given a clear liquid diet, progressing to a low-fat, high-carbohydrate diet. Vitamin B₁₂ may be ordered for parenteral administration to patients with decreased levels, especially if their disease prevents adequate absorption of the vitamin. The alcoholic patient should be encouraged to avoid alcohol and to seek appropriate counseling for substance abuse.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Teach the patient to use the incentive spirometer with deep cough to help maintain open airways and move secretions that interfere with adequate oxygenation
- ▶ Teach the patient the symptoms of fluid overload and deficit with an explanation of proper hydration.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Recognize anxiety related to test results, and answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ Demonstrates understanding of the link between alcohol use and disease process
- ▶ Describes symptoms that indicate being respiratory compromised and should be reported to the physician

Skills

- ▶ Accurately self-administers oxygen
- ▶ Proficiently monitors intake and output and records results accurately

Attitude

- ▶ Conforms with the therapeutic goals established by the HCP
- ▶ Verifies the necessity in refraining from activities that could cause a disease reoccurrence

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, ALP, AST, bilirubin, cancer antigens, calcium,

C-peptide, CBC WBC count and differential, CT pancreas, ERCP, fecal fat, GGT, lipase, magnesium, MRI pancreas, mumps serology, peritoneal fluid analysis, triglycerides, US abdomen, and US pancreas.

- ▶ See the Gastrointestinal and Hepatobiliary systems tables at the end of the book for related tests by body system.

Analgesic, Anti-inflammatory, and Antipyretic Drugs: Acetaminophen, Acetylsalicylic Acid

SYNONYM/ACRONYM: *Acetaminophen* (Acephen, Aceta, Apacet, APAP 500, Aspirin Free Anacin, Banesin, Cetaphen, Dapa, Datriil, Dorcol, Exocrine, FeverALL, Genapap, Genebs, Halenol, Little Fevers, Liquiprin, Mapap, Myapap, Nortemp, Pain Eze, Panadol, Paracetamol, Redutemp, Ridenol, Silapap, Tempa, Tylenol, Ty-Pap, Uni-Ace, Valorin); *Acetylsalicylic acid* (salicylate, aspirin, Anacin, Aspergum, Bufferin, Easprin, Ecotrin, Empirin, Measurin, Synalgos, ZORprin, ASA).

COMMON USE: To assist in monitoring therapeutic drug levels and detect toxic levels of acetaminophen and salicylate in suspected overdose and drug abuse.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

Drug	Therapeutic Range Conventional Units	Conversion to SI units	SI Units	Half-Life	Volume of Distribution	Protein Binding	Excretion
Acetaminophen	5–20 mcg/mL	SI units = Conventional Units x 6.62	33–132 micromol/L	1–3 hr	0.95 L/kg	20%–50%	85%–95% hepatic; metabolites, renal
Salicylate	10–30 mg/dL	SI units = Conventional Units x 0.073	0.7–2.2 mmol/L	2–3 hr	0.1–0.3 L/kg	90%–95%	1° hepatic; metabolites, renal

DESCRIPTION: Acetaminophen is used for headache, fever, and pain relief, especially for individuals unable to take salicylate products or who have bleeding conditions. It is the analgesic of choice for children less than 13 yr old; salicylates are avoided in this age group because of the association between aspirin and Reye's syndrome. Acetaminophen is rapidly absorbed from the gastrointestinal tract and reaches peak concentration within 30 to 60 min after administration of a therapeutic dose. It can be a silent killer because, by the time symptoms of intoxication appear 24 to 48 hr after ingestion, the antidote is ineffective. Acetylsalicylic acid (ASA) is also used for headache, fever, inflammation, and pain relief. Some patients with cardiovascular disease take small prophylactic doses. The main site of toxicity for both drugs is the liver, particularly in the presence of liver disease or decreased drug metabolism and excretion. Other medications indicated for use in controlling neuropathic pain include amitriptyline and nortriptyline. Detailed information is found in the monograph titled "Antidepressant Drugs (Cyclic): Amitriptyline, Nortriptyline, Protriptyline, Doxepin, Imipramine, Desipramine."

Many factors must be considered in interpreting drug levels, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and the ingestion of substances (e.g., foods, herbals, vitamins, and minerals) that can potentiate or inhibit the intended target concentration.

IMPORTANT NOTE: These medications are metabolized and excreted by the liver and kidneys and are therefore contraindicated in patients with hepatic or renal disease and cautiously advised in patients with renal impairment. Information regarding medication must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in calculation of future doses. If administration of the drug is delayed, notify the appropriate department(s) to reschedule the blood draw and notify the requesting health-care provider (HCP) if the delay has caused any real or perceived therapeutic harm.

This procedure is contraindicated for: N/A

INDICATIONS

- Suspected overdose
- Suspected toxicity
- Therapeutic monitoring

POTENTIAL DIAGNOSIS

Increased in

- Acetaminophen
 - Alcoholic cirrhosis (*related to inability of damaged liver to metabolize the drug*)
 - Liver disease (*related to inability of damaged liver to metabolize the drug*)
 - Toxicity
- ASA
 - Toxicity

Decreased in

- Noncompliance with therapeutic regimen

CRITICAL FINDINGS

Note: The adverse effects of subtherapeutic levels are also important. Care

should be taken to investigate signs and symptoms of too little and too much medication. Note and immediately report to the requesting HCP any critically increased or subtherapeutic values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Acetaminophen: Greater Than 200 mcg/mL (4 hr postingestion): (SI Greater Than 1,324 micromol/L [4 hr postingestion])

Signs and symptoms of acetaminophen intoxication occur in stages over a period of time. In stage I (0 to 24 hr after ingestion), symptoms may include gastrointestinal irritation, pallor, lethargy, diaphoresis, metabolic acidosis, and possibly coma. In stage II (24 to 48 hr after ingestion), signs and symptoms may include right upper quadrant abdominal pain; elevated liver enzymes, aspartate aminotransferase (AST), and alanine aminotransferase (ALT); and possible decreased

renal function. In stage III (72 to 96 hr after ingestion), signs and symptoms may include nausea, vomiting, jaundice, confusion, coagulation disorders, continued elevation of AST and ALT, decreased renal function, and coma. Intervention may include gastrointestinal decontamination (stomach pumping) if the patient presents within 6 hr of ingestion or administration of *N*-acetylcysteine (Mucomyst) in the case of an acute intoxication in which the patient presents more than 6 hr after ingestion.

ASA: Greater Than 40 mg/dL: (SI Greater Than 2.9 mmol/L)

Signs and symptoms of salicylate intoxication include ketosis, convulsions, dizziness, nausea, vomiting, hyperactivity, hyperglycemia, hyperpnea, hyperthermia, respiratory arrest, and tinnitus. Possible interventions include administration of activated charcoal as vomiting ceases, alkalization of the urine with bicarbonate, and a single dose of vitamin K (for rare instances of hypoprothrombinemia).

INTERFERING FACTORS

- Blood drawn in serum separator tubes (gel tubes).
- Drugs that may increase acetaminophen levels include diflunisal, metoclopramide, and probenecid.
- Drugs that may decrease acetaminophen levels include carbamazepine, cholestyramine, iron, oral contraceptives, and propantheline.
- Drugs that increase ASA levels include choline magnesium trisalicylate, cimetidine, furosemide, and sulfipyrazone.
- Drugs and substances that decrease ASA levels include activated charcoal, antacids (aluminum hydroxide), corticosteroids, and iron.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with evaluation of how much medication is in his or her system.
- ▶ Obtain a complete history of the time and amount of drug ingested by the patient.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Review results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a history of the patient's genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. These medications are metabolized and excreted by the kidneys and liver.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Lack of consideration for the proper collection time relative to the dosing schedule can provide misleading information that may result in erroneous interpretation of levels, creating the potential for a medication error–related injury to the patient.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to the dosing schedule. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop the bleeding. Observe/assess the venipuncture site for bleeding and hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Include avoidance of alcohol consumption.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding food and drug interactions. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Recognize anxiety related to test results, and explain to the patient the importance of following the medication regimen and instructions regarding food and drug interactions. Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, AST, bilirubin, biopsy liver, BUN, creatinine, electrolytes, glucose, lactic acid, aPTT, and PT/INR.
- ▶ See the Genitourinary and Hepatobiliary systems tables at the end of the book for related tests by body system.

Angiography, Abdomen

SYNONYM/ACRONYM: Abdominal angiogram, abdominal arteriography.

COMMON USE: To visualize and assess abdominal organs/structure for tumor, infection, or aneurysm.

AREA OF APPLICATION: Abdomen.

CONTRAST: Iodine based.

DESCRIPTION: Abdominal angiography allows x-ray visualization of the large and small arteries, veins, and associated branches of the abdominal vasculature and organ parenchyma after contrast medium injection. This visualization is accomplished by the injection of contrast medium through a catheter, which most commonly has been inserted into the femoral artery and advanced through the iliac artery and aorta into the organ-specific artery. Fluoroscopy is used to guide catheter placement, and angiograms (high-speed x-ray images) provide images of the organ of interest and associated vessels that are displayed on a monitor and are recorded for future viewing and evaluation. Digital subtraction angiography (DSA) is a computerized method of removing undesired structures, like bone, from the surrounding area of interest.

A digital image is taken prior to injection of the contrast and then again after the contrast has been injected. By subtracting the preinjection image from the postinjection image, a higher-quality, unobstructed image can be created. Patterns of circulation, organ function, and changes in vessel wall appearance can be viewed to help diagnose the presence of vascular abnormalities, aneurysm, tumor, trauma, or lesions. The catheter used to administer the contrast medium to confirm the diagnosis of organ lesions may be used to deliver chemotherapeutic drugs or different types of materials administered to stop bleeding. Catheters with attached inflatable balloons for angioplasty and wire mesh stents are used to widen areas of stenosis and to keep vessels open, frequently replacing surgery. Embolotherapy can also be accomplished through

the same catheter when the site of bleeding or extravasation is located. Angiography is one of the definitive tests for organ disease and may be used to evaluate chronic disease and organ failure, treat arterial stenosis, differentiate a vascular cyst from hypervascular cancers, and evaluate the effectiveness of medical or surgical treatment.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish (shellfish contain high levels of iodine), it has been well established that the reaction is not to iodine; an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of non-ionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moder-

ate to severe reactions to ionic contrast medium.

- ◆ Conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) ***because iodinated contrast is nephrotoxic.***
- ◆ Elderly and compromised patients who are chronically dehydrated before the test ***because of their risk of contrast-induced renal failure.***
- ◆ Patients with pheochromocytoma, ***because iodinated contrast may cause a hypertensive crisis.***
- ◆ Patients with bleeding disorders or receiving anticoagulant therapy ***because the puncture site may not stop bleeding.***

INDICATIONS

- Aid in angioplasty, atherectomy, or stent placement
- Allow infusion of thrombolytic drugs into an occluded artery
- Detect arterial occlusion, which may be evidenced by a transection of the artery caused by trauma or penetrating injury
- Detect artery stenosis, evidenced by vessel dilation, collateral vessels, or increased vascular pressure
- Detect nonmalignant tumors before surgical resection
- Detect thrombosis, arteriovenous fistula, aneurysms, or emboli in abdominal vessels
- Detect tumors and arterial supply, extent of venous invasion, and tumor vascularity
- Detect peripheral artery disease (PAD)
- Differentiate between tumors and cysts
- Evaluate organ transplantation for function or organ rejection

- Evaluate placement of a shunt or stent
- Evaluate tumor vascularity before surgery or embolization
- Evaluate the vascular system of prospective organ donors before surgery

POTENTIAL DIAGNOSIS

Normal findings in

- Normal structure, function, and patency of abdominal organ vessels
- Contrast medium normally circulates throughout abdomen symmetrically and without interruption
- No evidence of obstruction, variations in number and size of vessels, malformations, cysts, or tumors

Abnormal findings in

- Abscess or inflammation as seen by edema in the area of the vessel
- Arterial aneurysm visualized by a bulging in a vessel
- Arterial stenosis, dysplasia, or organ infarction indicated by a narrowing or blocked artery
- Arteriovenous fistula or other abnormalities
- Congenital anomalies
- Cysts visualized by areas with a halo of contrast surrounding them or tumors indicated by areas of increased density due to the vascularity which collects the contrast
- PAD
- Trauma causing tears or other disruption indicated by blood outside the vessel

CRITICAL FINDINGS

- Abscess
- Aneurysm

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP).

A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding

younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist with the evaluation of abdominal organs.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded

prior to the procedure; a creatinine level is also needed before contrast medium is to be used.

- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by an HCP and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal

saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.

- ▶ Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary among facilities.
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

- ▶ Establishing an IV site and injection of contrast medium by catheter are invasive procedures. Complications are rare but do include risk for allergic reaction (**related to contrast reaction**); bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners; postprocedural bleeding from the site is rare because at the conclusion of the procedure a resorbable device, composed of non-latex-containing arterial anchor, collagen plug, and suture, is deployed to seal the puncture site**); blood clot formation (**related to thrombus formation on the tip of the catheter sheath surface or in the lumen of the catheter; the use of a heparinized saline flush during the procedure decreases the risk of emboli**); hematoma (**related to blood leakage into the tissue following needle insertion**); infection (**which might occur if bacteria from the skin surface is introduced at the puncture site**); tissue damage (**related to extravasation of the contrast during**

injection); or nerve injury or damage to a nearby organ (**which might occur if the catheter strikes a nerve or perforates an organ**).

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary and fluid restrictions for 2 to 4 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reaction to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.
- ▶ Using a pen, mark the site of the patient's peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- ▶ Place the patient in the supine position on an examination table. Cleanse the selected area, and cover with a sterile drape.

- ▶ A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy.
- ▶ The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary among facilities.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.

- ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to maintain bedrest for 4 to 6 hr after the procedure or as ordered.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Provide contact information, if desired, for the American Heart Association (www.americanheart.org), or the National Heart, Lung, and Blood Institute (www.nhlbi.nih.gov), or the Legs for Life (www.legsforlife.org).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography renal, BUN, CT abdomen, CT angiography, CT brain, CT spleen, CT thoracic, creatinine, KUB, MRA, MRI abdomen, MRI brain, MRI chest, MRI pelvis, aPTT, PT/INR, renogram, US abdomen, and US lower extremity.
- ▶ See the Cardiovascular System table at the end of the book for related tests by body system.

Angiography, Adrenal

SYNONYM/ACRONYM: Adrenal angiogram, adrenal arteriography.

COMMON USE: To visualize and assess the adrenal gland for cancer or other tumors or masses.

AREA OF APPLICATION: Adrenal gland.

CONTRAST: Iodine based.

DESCRIPTION: Adrenal angiography evaluates adrenal dysfunction by allowing x-ray visualization of the large and small arteries of the adrenal gland vasculature and parenchyma. This visualization is accomplished by the injection of contrast medium through a catheter that has been inserted into the femoral artery for viewing the artery (arteriography) or into the femoral vein for viewing the veins (venography). Fluoroscopy is used to guide catheter placement, and angiograms (high-speed x-ray images) provide images of the adrenal glands and associated vessels surrounding the adrenal tissue which are displayed on a monitor and are recorded for future viewing and evaluation. Digital subtraction angiography (DSA) is a computerized method of removing undesired structures, like bone, from the surrounding area of interest. A digital image is taken prior to injection of the contrast and then again after the contrast has been injected. By subtracting the preinjection image from the postinjection image a higher-quality, unobstructed image can be created. Patterns of circulation, adrenal function, and changes in vessel wall appearance can be viewed to help diagnose the presence of vascular abnormalities, trauma, or

lesions. This definitive test for adrenal disease may be used to evaluate chronic adrenal disease, evaluate arterial or venous stenosis, differentiate an adrenal cyst from adrenal tumors, identify pheochromocytoma, and evaluate medical therapy or surgery of the adrenal glands.

Imaging studies cannot always visualize a tumor, especially if it is small. Adrenal venous sampling can be very challenging beginning with proper placement of the catheter; after the catheter is in place, blood samples may be taken from the vein of each gland and the distal portion of the vena cava to assess cortisol and ACTH levels. The information is used to assist in determining a diagnosis of ACTH-independent Cushing's syndrome (benign or malignant adrenal growth that secretes cortisol) or primary hyperaldosteronism (excessive adrenal gland production of aldosterone). The gold standard for distinguishing between a cortisol-secreting tumor and unilateral or bilateral adrenal hyperplasia is considered to be measurement of aldosterone/cortisol ratios taken from a series of samples during adrenal angiography. Cortisol levels will be elevated if related to Cushing's syndrome. A ratio of greater than 4:1 is indicative of

unilateral hyperplasia. Ratios between each gland are similar and usually less than 3:1 in the presence of bilateral hyperplasia. Obtaining the correct diagnosis from the angiogram is important because treatment for adrenal adenoma and unilateral adrenal hyperplasia is surgical removal of the affected adrenal gland, while bilateral adrenal hypertrophy is treated medically.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish (shellfish contain high levels of iodine), it has been well established that the reaction is not to iodine; an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of non-ionic contrast or an alternative non-contrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
-  Conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
-  Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure.**
-  Patients with pheochromocytoma **because iodinated contrast may cause a hypertensive crisis.**
-  Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Assist in the infusion of thrombolytic drugs into an occluded artery
- Assist with the collection of blood samples from the vein for laboratory analysis
- Detect adrenal hyperplasia
- Detect and determine the location of adrenal tumors evidenced by arterial supply, extent of venous invasion, and tumor vascularity
- Detect arterial occlusion, evidenced by a transection of the artery caused by trauma or a penetrating injury
- Detect arterial stenosis, evidenced by vessel dilation, collateral vessels, or increased vascular pressure
- Detect nonmalignant tumors before surgical resection
- Detect thrombosis, arteriovenous fistula, aneurysms, or emboli in vessels
- Differentiate between adrenal tumors and adrenal cysts
- Evaluate tumor vascularity before surgery or embolization
- Perform angioplasty, perform atherectomy, or place a stent

POTENTIAL DIAGNOSIS**Normal findings in**

- Normal structure, function, and patency of adrenal vessels
- Contrast medium circulating throughout the adrenal gland symmetrically and without interruption
- No evidence of obstruction, variations in number and size of vessels and organs, malformations, cysts, or tumors

Abnormal findings in

- Adrenal adenoma
- Adrenal carcinoma
- Bilateral adrenal hyperplasia
- Pheochromocytoma

CRITICAL FINDINGS: N/A**INTERFERING FACTORS****Factors that may impair clear imaging**

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher

radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist with evaluation of the adrenal gland (located near the kidney).
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; a creatinine level is also needed before contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure

that barium studies were performed more than 4 days before angiography.

- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by an HCP and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.
- ▶ Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.

- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary among facilities.
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- ▶ Establishing an IV site and injection of contrast medium by catheter are invasive procedures. Complications are rare but do include risk for allergic reaction (**related to contrast reaction**); bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners; postprocedural bleeding from the site is rare because at the conclusion of the procedure a resorbable device, composed of non-latex-containing arterial anchor, collagen plug, and suture, is deployed to seal the puncture site**); blood clot formation (**related to thrombus formation on the tip of the catheter sheath surface or in the lumen of the catheter, but the use of a heparinized saline flush during the procedure decreases the risk of emboli**); hematoma (**related to blood leakage into the tissue following needle insertion**); infection (**which might occur if bacteria from the skin surface is introduced at the puncture site**); tissue damage (**related to extravasation of the contrast during injection**); or nerve injury or damage to a nearby organ (**which might occur if the catheter strikes a nerve or perforates an organ**).
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.

- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
 - ▶ Administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure if the patient has a history of allergic reactions to any substance or drug.
 - ▶ Have emergency equipment readily available.
 - ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
 - ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
 - ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
 - ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
 - ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.
 - ▶ Using a pen, mark the site of the patient's peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
 - ▶ Place the patient in the supine position on an examination table. Cleanse the selected area, and cover with a sterile drape.
 - ▶ A local anesthetic is injected at the site, and a small incision is made or a needle inserted under fluoroscopy.
 - ▶ The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.
 - ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
 - ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
 - ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
 - ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
 - ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- POST-TEST:**
- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
 - ▶ Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
 - ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary among facilities.
 - ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
 - ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
 - ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
 - ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
 - ▶ Instruct the patient in the care and assessment of the site.
 - ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
 - ▶ Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.

- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor

progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH and challenge tests, adrenal gland scan, BUN, catecholamines, cortisol and challenge tests, creatinine, CT abdomen, HVA, KUB study, metanephrines, MRI abdomen, aPTT, PT/INR, renin, and VMA.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Angiography, Carotid

SYNONYM/ACRONYM: Carotid angiogram, carotid arteriography.

COMMON USE: To visualize and assess the carotid arteries and surrounding tissues for abscess, tumors, aneurysm, and evaluate for atherosclerotic disease related to stroke risk.

AREA OF APPLICATION: Neck/cervical area.

CONTRAST: Iodine based.

DESCRIPTION: This test evaluates blood vessels in the neck carrying arterial blood to the brain and is accomplished by the injection of contrast material through a catheter that has been inserted into the femoral artery. Fluoroscopy is used to guide catheter placement and angiograms (high-speed x-ray images) provide images of the carotid artery and associated vessels in surrounding tissue which are displayed on a monitor and are recorded for future viewing and evaluation. Digital subtraction angiography (DSA) is a computerized method of removing unde-

sired structures, like bone, from the surrounding area of interest. A digital image is taken prior to injection of the contrast and then again after the contrast has been injected. By subtracting the preinjection image from the postinjection image a higher-quality, unobstructed image can be created. The x-ray equipment is mounted on a C-shaped arm with the x-ray device beneath the table on which the patient lies. Over the patient is an image intensifier that receives the x-rays after they pass through the patient. Patterns of circulation or changes in vessel wall

appearance can be viewed to help diagnose the presence of vascular abnormalities, disease, narrowing, enlargement, blockage, trauma, or lesions. This definitive test for arterial disease may be used to evaluate chronic vascular disease, arterial or venous stenosis, and medical therapy or surgery of the vasculature. Catheter angiography still is used in patients who may undergo surgery, angioplasty, or stent placement.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish (shellfish contain high levels of iodine), it has been well established that the reaction is not to iodine; an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced

moderate to severe reactions to ionic contrast medium.

-  Conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
-  Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure.**
-  Patients with pheochromocytoma **because iodinated contrast may cause a hypertensive crisis.**
-  Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Aid in angioplasty, atherectomy, or stent placement
- Allow infusion of thrombolytic drugs into an occluded artery
- Detect arterial occlusion, which may be evidenced by a transection of the artery caused by trauma or penetrating injury
- Detect artery stenosis, evidenced by vessel dilation, collateral vessels, or increased vascular pressure
- Detect nonmalignant tumors before surgical resection
- Detect tumors and arterial supply, extent of venous invasion, and tumor vascularity
- Detect thrombosis, arteriovenous fistula, aneurysms, or emboli in vessels
- Evaluate placement of a stent
- Differentiate between tumors and cysts
- Evaluate tumor vascularity before surgery or embolization
- Evaluate the vascular system of prospective organ donors before surgery

POTENTIAL DIAGNOSIS

Normal findings in

- Normal structure, function, and patency of carotid arteries
- Contrast medium normally circulates throughout neck symmetrically and without interruption
- No evidence of obstruction, variations in number and size of vessels, malformations, cysts, or tumors

Abnormal findings in

- Abscess or inflammation
- Arterial stenosis or dysplasia
- Aneurysms
- Arteriovenous fistula or other abnormalities
- Congenital anomalies
- Cysts or tumors
- Trauma causing tears or other disruption
- Vascular blockage or other disruption

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety

concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist with evaluation of the cardiovascular system.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; a creatinine

level is also needed before contrast medium is to be used.

- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by an HCP and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.

- ▶ Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary among facilities.
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- ▶ Establishing an IV site and injection of contrast medium by catheter are invasive procedures. Complications are rare but do include risk for: allergic reaction (**related to contrast reaction**); bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners—postprocedural bleeding from the site is rare because at the conclusion of the procedure a resorbable device, composed of non-latex-containing arterial anchor, collagen plug, and suture, is deployed to seal the puncture site**); blood clot formation (**related to thrombus formation on the tip of the catheter sheath surface or in the lumen of the catheter—the use of a heparinized saline flush during the procedure decreases the risk of emboli**); hematoma (**related to blood leakage into the tissue following needle insertion**); infection (**that might occur if bacteria from the skin surface is introduced at the puncture site**); tissue damage (**related to extravasation of the contrast during injection**); or nerve injury or damage to a nearby organ (**which might occur**

if the catheter strikes a nerve or perforates an organ).

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer an anti-anxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.
- ▶ Using a pen, mark the site of the patient's peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- ▶ Place the patient in the supine position on an examination table. Cleanse the selected area, and cover with a sterile drape.
- ▶ A local anesthetic is injected at the site, and a small incision is made or a needle is inserted under fluoroscopy.

- ▶ The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary from facility to facility.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.

- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to maintain bedrest for 4 to 6 hr after the procedure or as ordered.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the

importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography abdomen, BUN, CT angiography, CT brain, creatinine, ECG, exercise stress test, MRA, MRI brain, PT/INR, plethysmography, US arterial Doppler lower extremities, and US peripheral Doppler.
- ▶ See the Cardiovascular System table at the end of the book for related tests by body system.

Angiography, Coronary

SYNONYM/ACRONYM: Angiography of heart, angiocardiography, cardiac angiography, cardiac catheterization, cineangiocardiography, coronary angiography, coronary arteriography.

COMMON USE: To visualize and assess the heart and surrounding structure for abnormalities, defects, aneurysm, and tumors.

AREA OF APPLICATION: Heart.

CONTRAST: Intravenous or intra-arterial iodine based.

DESCRIPTION: Angiography allows x-ray visualization of the heart, aorta, inferior vena cava, pulmonary artery and vein, and coronary

arteries after injection of contrast medium. Contrast medium is injected through a catheter, which has been inserted into a peripheral

vein, usually the femoral or brachial vein, for a right heart catheterization or into an artery, usually the femoral or brachial artery, for a left heart catheterization; through the same catheter cardiac pressures and volumes are recorded.

Fluoroscopy is used to guide catheter placement, and angiograms (high-speed x-ray images) provide images of the heart and associated vessels which are displayed on a monitor and are recorded for future viewing and evaluation. Digital subtraction angiography (DSA) is a computerized method of removing undesired structures, like bone, from the surrounding area of interest. A digital image is taken prior to injection of the contrast and then again after the contrast has been injected. By subtracting the preinjection image from the postinjection image a higher-quality, unobstructed image can be created.

Patterns of circulation, cardiac output, cardiac functions, and changes in vessel wall appearance can be viewed to help diagnose the presence of vascular abnormalities or lesions. Pulmonary artery abnormalities are seen with right heart views, and coronary artery and thoracic aorta abnormalities are seen with left heart views. Coronary angiography is useful for evaluating cardiovascular disease and various types of cardiac abnormalities.

Coronary angiography, more commonly called cardiac catheterization, is a definitive test for coronary artery disease (CAD). CAD is a condition where the blood vessels to the heart lose their elasticity and become narrowed by atherosclerotic deposits of plaque. Significant blockage is treatable using coronary artery bypass grafting (CABG) surgery. Cardiac catheterization can also be used

in conjunction with less invasive interventional alternatives to CABG surgery such as percutaneous transluminal coronary angioplasty (PTCA), with or without placement of stents. PTCA is also known as balloon angioplasty because once the blockage is identified and determined to be treatable, a balloon catheter is used to help correct the problem. The balloon in the catheter is inflated to compress the plaque against the sides of the affected vessel. The balloon may be inflated multiple times and with increasing size to increase the diameter of the vessel's lumen which restores more normal blood flow. A stent, which is a small mesh tube, may be placed in the affected vessel to keep it open after the angioplasty is completed.

Carotid endarterectomy (CEA) is another procedure that can be combined with coronary angiography and may also be part of the PTCA procedure. CEA is performed to reduce stroke risk. Stroke results from severe stenosis of the carotid arteries and release of plaque emboli that travel to the brain, block circulation, and cause brain tissue death. The CEA procedure involves insertion of an additional, separate catheter to insert a device that removes plaque from the walls of the carotid arteries. The devices commonly used to perform CEA employ very small drills or rotating blades to remove the plaque. Balloon angioplasty, with or without stent placement, usually follows CEA.

Applications of Cardiac Catheterization for Infants and Pediatric Patients Cardiac catheterization is very useful in identification of the type of heart defect, determination of the exact

location of the defect, and indications regarding the severity of the defect. Some of the common operable heart defects in infants and children include repairs for ventricular septal defects, atrial septic defects, tetralogy of Fallot, valve defects, and arterial switches. Cardiac catheterization can also be used as a palliative procedure prior to arterial switch repair. The catheterization, called a balloon atrial septostomy, is used to create a small hole in the inner wall of the heart between the atria that allows a greater volume of oxygenated blood to enter the circulatory system. The improved quality of circulating blood provides some time for very young patients to gain strength prior to the surgical repair. The hole is closed when the corrective surgery is completed.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish (shellfish contain high levels of iodine), it has been well established that the reaction is not to iodine; an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of

the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

-  Conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) ***because iodinated contrast is nephrotoxic.***
-  Elderly and compromised patients who are chronically dehydrated before the test ***because of their risk of contrast-induced renal failure.***
-  Patients with pheochromocytoma, ***because iodinated contrast may cause a hypertensive crisis.***
-  Patients with bleeding disorders or receiving anticoagulant therapy ***because the puncture site may not stop bleeding.***

INDICATIONS

- Allow infusion of thrombolytic drugs into an occluded coronary
- Detect narrowing of coronary vessels or abnormalities of the great vessels in patients with angina, syncope, abnormal electrocardiogram, hypercholesterolemia with chest pain, and persistent chest pain after revascularization
- Evaluate cardiac muscle function
- Evaluate cardiac valvular and septal defects
- Evaluate disease associated with the aortic arch
- Evaluate previous cardiac surgery or other interventional procedures

- Evaluate peripheral artery disease (PAD)
- Evaluate peripheral vascular disease (PVD)
- Evaluate ventricular aneurysms
- Monitor pulmonary pressures and cardiac output
- Perform angioplasty, perform atherectomy, or place a stent
- Quantify the severity of atherosclerotic, occlusive coronary artery disease

POTENTIAL DIAGNOSIS

Normal findings in

- Normal great vessels and coronary arteries

Normal Adult Hemodynamic Pressures and Volumes Monitored During Coronary Angiography (Cardiac Catheterization)

Pressures	Description of What Measured Parameter Represents	Normal Value
Arterial blood pressure (also known as routine blood pressure)	The pressure in the brachial artery; one of the significant vital signs, it reflects the pressure the heart exerts to pump blood through the circulatory system.	Systolic (100–140) mm Hg/diastolic (60–90) mm Hg
Mean arterial pressure	The average arterial pressure of one cardiac cycle; considered a better indicator of perfusion than routine blood pressure but only obtainable by direct measurement during cardiac catheterization.	70–105 mm Hg
Left ventricular pressures	Peak pressure in the left ventricle during systole/Peak pressure in the left ventricle at the end of diastole; indication of contractility of the heart muscle.	Systolic (90–140) mm Hg/diastolic (4–12) mm Hg
Central venous pressure (right atrial pressure)	The right-sided ventricular pressures exerted by the central veins closest to the heart (jugular, subclavian, or femoral); used to estimate blood volume and venous return.	2–6 mm Hg
Pulmonary artery pressure	The pressures in the pulmonary artery	Systolic (15–30) mm Hg/diastolic (4–12) mm Hg
Pulmonary artery wedge pressure	The pressure in the pulmonary vessels; used to provide an estimate of left atrial filling pressure, to provide an estimate of left ventricle pressure during end diastole, and a way to measure ventricular preload.	4–12 mm Hg
Volumes		
Cardiac output	The amount of blood pumped out by the ventricle of the heart in 1 min	4–8 L/min

(table continues on page 94)

Pressures	Description of What Measured Parameter Represents	Normal Value
Cardiac index	The cardiac output adjusted for body surface to provide the index which is a more precise measurement; used to assess the function of the ventricle.	2.5–4 L/min/m ²
Arterial oxygen saturation	The concentration of oxygen in the blood.	95–100%
Stroke volume	The amount of blood pumped by each ventricle with each time it contracts in a heartbeat.	60–100 mL/beat
Stroke volume index	The stroke volume adjusted for body surface to provide the index which is a more precise measurement.	33–57 mL/m ²
End diastolic volume (EDV)	The amount of blood in the left ventricle at the end of diastole.	100–160 mL
EDV index	EDV adjusted for body surface to provide the index which is a more precise measurement.	50–80 mL/m ²
End systolic volume (ESV)	The amount of blood in the left ventricle at the end of systole.	50–100 mL
ESV index	ESV adjusted for body surface to provide the index which is a more precise measurement.	25–50 mL/m ²
Ejection fraction	Stroke volume expressed as a percentage of end diastolic volume.	65%

Abnormal findings in

- Aortic atherosclerosis
- Aortic dissection
- Aortitis
- Aneurysms
- Cardiomyopathy
- Congenital anomalies
- Coronary artery atherosclerosis and degree of obstruction
- Graft occlusion
- PAD
- PVD
- Pulmonary artery abnormalities
- Septal defects
- Trauma causing tears or other disruption
- Tumors
- Valvular disease

CRITICAL FINDINGS

- Aneurysm
- Aortic dissection

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record

with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel

working in the examination area should wear badges to record their level of radiation exposure.

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist with assessment of cardiac function and check for heart disease.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of results of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; a creatinine level is also needed before contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.
- ▶ Record the date of last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be

discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by an HCP and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.
- ▶ Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary among facilities.
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- ▶ Establishing an IV site and injection of contrast medium by catheter are invasive procedures. Complications are rare but do include risk for: allergic reaction (**related to contrast reaction**); bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners—postprocedural bleeding from the site is rare because at the conclusion of the procedure a resorbable device, composed of non-latex-containing arterial anchor, collagen plug, and suture, is deployed to seal the puncture site**); blood clot formation (**related to thrombus formation on the tip of the catheter sheath surface or in the lumen of the catheter—the use of a heparinized saline flush during the procedure decreases the risk of emboli**); hematoma (**related to blood leakage into the tissue following needle insertion**); infection (**which might occur if bacteria from the skin surface is introduced at the puncture site**); tissue damage (**related to extravasation of the contrast during injection**); or nerve injury or damage to a nearby organ (**which might occur if the catheter strikes a nerve or perforates an organ**).
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary and fluid restrictions for 2 to 4 hr prior to the procedure.
- ▶ Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.
- ▶ Using a pen, mark the site of the patient's peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- ▶ Place the patient in the supine position on an examination table. Cleanse the selected area, and cover with a sterile drape.
- ▶ A local anesthetic is injected at the site, and a small incision is made or a needle is inserted under fluoroscopy.
- ▶ The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, or activity as directed by the HCP. Renal function should be assessed before metformin is resumed.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary from facility to facility.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site and to observe for bleeding, hematoma formation, bile leakage, and inflammation. Any pleuritic pain, persistent right shoulder pain, or abdominal pain should be reported to the appropriate HCP.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to maintain bedrest for 4 to 6 hr after the procedure or as ordered.

- ▶ **Nutritional Considerations:** Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation of moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the ACC and AHA in conjunction with the NHLBI recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the DASH diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications

of the test results, as appropriate. Provide contact information, if desired, for the American Heart Association (www.americanheart.org), the National Heart, Lung, and Blood Institute (www.nhlbi.nih.gov), and the Legs for Life (www.legsforlife.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography carotid, blood pool imaging, BNP, BUN, chest x-ray, cholesterol HDL and LDL, cholesterol total, CT abdomen, CT angiography, CT biliary tract and liver, CT cardiac scoring, CT spleen, CT thoracic, CK, creatinine, CRP, electrocardiography, electrocardiography transesophageal, Holter monitor, homocysteine, lipoprotein electrophoresis, MR angiography, MRI abdomen, MRI chest, myocardial perfusion heart scan, plethysmography, aPTT, PT/INR, triglycerides, troponin, and US arterial Doppler carotid.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Angiography, Pulmonary

SYNONYM/ACRONYM: Pulmonary angiography, pulmonary arteriography.

COMMON USE: To visualize and assess the lungs and surrounding structure for abscess, tumor, cancer, defects, tuberculosis, and pulmonary embolism.

AREA OF APPLICATION: Pulmonary vasculature.

CONTRAST: Intravenous iodine based.

DESCRIPTION: Pulmonary angiography allows x-ray visualization of the pulmonary vasculature after injection of an iodinated contrast medium into the pulmonary artery or a branch of this great vessel. Contrast medium is injected through a catheter that has been inserted into the vascular system, usually through the femoral or brachial vein. Fluoroscopy is used to guide catheter placement, and angiograms (high-speed x-ray images) provide images of the pulmonary vessels which are displayed on a monitor and are recorded for future viewing and evaluation. Digital subtraction angiography (DSA) is a computerized method of removing undesired structures, like bone, from the surrounding area of interest. A digital image is taken prior to injection of the contrast and then again after the contrast has been injected. By subtracting the preinjection image from the postinjection image a higher-quality, unobstructed image can be created. It is one of the definitive tests for pulmonary embolism, but it is also useful for evaluating other types of pulmonary vascular abnormalities. It is definitive for peripheral pulmonary artery stenosis, anomalous pulmonary

venous drainage, and pulmonary fistulae. Hemodynamic measurements during pulmonary angiography can assist in the diagnosis of pulmonary hypertension and cor pulmonale. Pulmonary angiograms are requested less frequently in favor of CT pulmonary angiograms which are less invasive, faster, have fewer complications, and are of similar quality.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish (shellfish contain high levels of iodine), it has been well established that the reaction is not to iodine; an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the

reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure.**
- ◆ Patients with pheochromocytoma **because iodinated contrast may cause a hypertensive crisis.**
- ◆ Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Detect acute pulmonary embolism
- Detect arteriovenous malformations or aneurysms
- Detect tumors; aneurysms; congenital defects; vascular changes associated with emphysema, blebs, and bullae; and heart abnormalities
- Determine the cause of recurrent or severe hemoptysis
- Evaluate pulmonary circulation

POTENTIAL DIAGNOSIS

Normal findings in

- Normal pulmonary vasculature; radiopaque iodine contrast medium should circulate symmetrically and without interruption through the pulmonary circulatory system.

Abnormal findings in

- Aneurysms
- Arterial hypoplasia or stenosis
- Arteriovenous malformations
- Bleeding caused by tuberculosis, bronchiectasis, sarcoidosis, or aspergilloma
- Inflammatory diseases
- Pulmonary embolism (PE) acute or chronic (**visualized as an area of interrupted opacity in the pulmonary artery**)
- Pulmonary sequestration
- Tumors

CRITICAL FINDINGS

- PE

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any

orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist with assessment of lung function and check for disease.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's cardiovascular and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; a creatinine level is also needed before contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes

fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).

- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology or vascular suite by an HCP and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.
- ▶ Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary among facilities.
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Injection of the contrast by inserting a catheter into a blood vessel is an invasive procedure. Complications are rare but do include risk for: allergic reaction (**related to contrast reaction**); bleeding (**related to perforation of the blood vessel—postprocedural bleeding from the site is rare because at the conclusion of the procedure a resorbable device, composed of non-latex-containing arterial anchor,**

- collagen plug, and suture, is deployed to seal the puncture site**); blood clot formation (**related to thrombus formation on the tip of the catheter sheath surface or in the lumen of the catheter—the use of a heparinized saline flush during the procedure decreases the risk of emboli**); hematoma (**related to blood leakage into the tissue following insertion of the catheter**); infection (**which might occur if bacteria from the skin surface is introduced during catheter insertion**); tissue damage (**related to extravasation of the contrast during injection**); or nerve injury or damage to a nearby organ (**which might occur if the catheter strikes a nerve or perforates an organ**).
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations for 2 to 4 hr prior to the procedure.
 - ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
 - ▶ Administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure if the patient has a history of allergic reactions to any substance or drug.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Have emergency equipment readily available.
 - ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
 - ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
 - ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
 - ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative

to a child or to an uncooperative adult, as ordered.

- ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.
- ▶ Using a pen, mark the site of the patient's peripheral pulses before angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.
- ▶ Place the patient in the supine position on an examination table. Cleanse the selected area, and cover with a sterile drape.
- ▶ A local anesthetic is injected at the site, and a small incision is made or a needle is inserted under fluoroscopy.
- ▶ The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take the temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary from facility to facility.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia,

hyperpnea, hypertension, palpitations, nausea, or vomiting.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to maintain bedrest for 4 to 6 hr after the procedure or as ordered.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include alveolar/arterial gradient, blood gases, BNP, BUN, chest x-ray, creatinine, CT angiography, CT thoracic, ECG, FDP, lactic acid, lung perfusion scan, lung ventilation scan, MRA, MRI chest, MRI venography, aPTT, and PT/INR.
- ▶ Refer to the Cardiovascular and Respiratory systems tables at the end of the book for related tests by body system.

Angiography, Renal

SYNONYM/ACRONYM: Renal angiogram, renal arteriography.

COMMON USE: To visualize and assess the kidneys and surrounding structure for tumor, cancer, absent kidney, and level of renal disease.

AREA OF APPLICATION: Kidney.

CONTRAST: Intra-arterial iodine based.

DESCRIPTION: Renal angiography allows x-ray visualization of the large and small arteries of the renal vasculature and parenchyma or the renal veins and their branches. Contrast medium is injected through a catheter that has been inserted into the femoral artery or vein and advanced through the iliac artery and aorta into the renal artery or the inferior vena cava into the renal vein. Fluoroscopy is used to guide catheter placement, and angiograms (high-speed x-ray images) provide images of the kidneys and associated vessels which are displayed on a monitor and are recorded for future viewing and evaluation. Digital subtraction angiography (DSA) is a computerized method of removing undesired structures, like bone, from the surrounding area of interest. A digital image is taken prior to injection of the contrast and then again after the contrast has been injected. By subtracting the preinjection image from the postinjection image a higher-quality, unobstructed image can be created. Patterns of circulation, renal function, or changes in vessel wall appearance can be viewed to help diagnose the presence of vascular abnormalities, trauma, or lesions. This definitive

test for renal disease may be used to evaluate chronic renal disease, renal failure, and renal artery stenosis; differentiate a vascular renal cyst from hypervascular renal cancers; and evaluate renal transplant donors, recipients, and the kidney after transplantation.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish (shellfish contain high levels of iodine), it has been well established that the reaction is not to iodine; an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule.

- ◆ Conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure.**
- ◆ Patients with pheochromocytoma **because iodinated contrast may cause a hypertensive crisis.**
- ◆ Patients with bleeding disorders receiving an arterial or venous puncture **because the site may not stop bleeding.**

INDICATIONS

- Aid in angioplasty, atherectomy, or stent placement
- Allow infusion of thrombolytic drugs into an occluded artery
- Assist with the collection of blood samples from renal vein for renin analysis
- Detect arterial occlusion as evidenced by a transection of the renal artery caused by trauma or a penetrating injury
- Detect nonmalignant tumors before surgical resection
- Detect renal artery stenosis as evidenced by vessel dilation, collateral vessels, or increased renovascular pressure
- Detect renal tumors as evidenced by arterial supply, extent of venous invasion, and tumor vascularity
- Detect small kidney or absence of a kidney
- Detect thrombosis, arteriovenous fistulae, aneurysms, or emboli in renal vessels
- Differentiate between renal tumors and renal cysts

- Evaluate placement of a stent
- Evaluate postoperative renal transplantation for function or organ rejection
- Evaluate renal function in chronic renal failure or end-stage renal disease or hydronephrosis
- Evaluate the renal vascular system of prospective kidney donors before surgery
- Evaluate tumor vascularity before surgery or embolization

POTENTIAL DIAGNOSIS

Normal findings in

- Normal structure, function, and patency of renal vessels
- Contrast medium circulating throughout the kidneys symmetrically and without interruption
- No evidence of obstruction, variations in number and size of vessels and organs, malformations, cysts, or tumors

Abnormal findings in

- Abscess or inflammation
- Arterial stenosis, dysplasia, or infarction
- Arteriovenous fistula or other abnormalities
- Congenital anomalies
- Intrarenal hematoma
- Renal artery aneurysm
- Renal cysts or tumors
- Trauma causing tears or other disruption

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.

- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessment of

kidney function and check for disease.

- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure results of coagulation testing are obtained and recorded prior to the procedure; a creatinine level is also needed before contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium or barium. Ensure that barium studies were performed more than 4 days before angiography.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a

radiology or vascular suite by an HCP and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.
- ▶ Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- ▶ Instruct the patient to remove jewelry, and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure. Protocols may vary among facilities.
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Establishing an IV site and injection of contrast medium by catheter are invasive procedures. Complications are rare but do include risk for allergic reaction (**related to contrast reaction**); bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners—postprocedural bleeding from the site is rare because at the conclusion of the procedure a resorbable device, composed of non-latex-containing arterial anchor, collagen plug, and suture, is deployed to seal the puncture site**); blood clot formation (**related to thrombus formation on the tip of the catheter sheath surface or in the lumen of the catheter—the use of a heparinized saline flush**

during the procedure decreases the risk of emboli); hematoma (**related to blood leakage into the tissue following needle insertion**); infection (**which might occur if bacteria from the skin surface is introduced at the puncture site**); tissue damage (**related to extravasation of the contrast during injection**); or nerve injury or damage to a nearby organ (**which might occur if the catheter strikes a nerve or perforates an organ**).

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions for 2 to 4 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer an anti-anxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish a baseline rhythm; determine if the patient has ventricular arrhythmias.
- ▶ Using a pen, mark the site of the patient's peripheral pulses before

angiography; this allows for quicker and more consistent assessment of the pulses after the procedure.

- ▶ Place the patient in the supine position on an examination table. Cleanse the selected area, and cover with a sterile drape.
- ▶ A local anesthetic is injected at the site, and a small incision is made or a needle is inserted under fluoroscopy.
- ▶ The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary among facilities.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to maintain bedrest for 4 to 6 hr after the procedure or as ordered.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy kidney, BUN, creatinine, CT abdomen, CT angiography, culture urine, cytology urine, KUB study, IVP, MRA, MRI abdomen, aPTT, PT/INR, renin, renogram, US kidney, and UA.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Angiotensin-Converting Enzyme

SYNONYM/ACRONYM: Angiotensin I-converting enzyme (ACE).

COMMON USE: To assist in diagnosing, evaluating treatment, and monitoring the progression of sarcoidosis, a granulomatous disease that primarily affects the lungs.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 16.667)
0–2 yr	5–83 units/L	83–1383 nKat/L
3–7 yr	8–76 units/L	133–1267 nKat/L
8–14 yr	6–89 units/L	100–1483 nKat/L
Greater than 14 yr	12–68 units/L	200–1133 nKat/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Bronchitis (acute and chronic) *(related to release of ACE from damaged pulmonary tissue)*
- Connective tissue disease *(related to release of ACE from scarred and damaged pulmonary tissue)*
- Gaucher's disease *(related to release of ACE from damaged pulmonary tissue; Gaucher's disease is due to the hereditary deficiency of an enzyme that results in accumulation of a fatty substance that damages pulmonary tissue)*
- Hansen's disease (leprosy)
- Histoplasmosis and other fungal diseases

- Hyperthyroidism (untreated) *(related to possible involvement of thyroid hormones in regulation of ACE)*
- Pulmonary fibrosis *(related to release of ACE from damaged pulmonary tissue)*
- Rheumatoid arthritis *(related to development of interstitial lung disease, pulmonary fibrosis, and release of ACE from damaged pulmonary tissue)*
- Sarcoidosis *(related to release of ACE from damaged pulmonary tissue)*

Decreased in

- Advanced pulmonary carcinoma *(related to lack of functional cells to produce ACE)*
- The period following corticosteroid therapy for sarcoidosis *(evidenced by cessation of effective therapy)*

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Anion Gap

A

SYNONYM/ACRONYM: Agap.

COMMON USE: To assist in diagnosing metabolic disorders that result in metabolic acidosis and electrolyte imbalance such as severe dehydration.

SPECIMEN: Serum (1 mL) for electrolytes collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Anion gap is derived mathematically from the direct measurement of sodium, chloride, and total carbon dioxide.) There are differences between serum and plasma values for some electrolytes. The reference ranges listed are based on serum values.

Age

Conventional and SI Units

Child or adult

8–16 mmol/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Metabolic acidosis that results from the accumulation of unmeasured anionic substances like proteins, phosphorus, sulfates, ketoacids, or other organic acid waste products of metabolism

- Dehydration (severe)
- Ketoacidosis *caused by starvation, high-protein/low-carbohydrate diet, diabetes, and alcoholism*
- Lactic acidosis (*shock, excessive exercise, some malignancies*)
- Poisoning (salicylate, methanol, ethylene glycol, or paraldehyde)
- Renal failure
- Uremia

Decreased in

Conditions that result in metabolic alkalosis

- Chronic vomiting or gastric suction (*related to alkalosis due to net loss of acid*)
- Excess alkali ingestion
- Hypergammaglobulinemia (*related to an increase in measurable anions relative to the excessive production of unmeasured cationic M proteins*)
- Hypoalbuminemia (*related to decreased levels of unmeasured anionic proteins relative to stable and measurable cation concentrations*)
- Hyponatremia (*related to net loss of cations*)

Significant acidosis or alkalosis can result from increased levels of unmeasured cations like ionized calcium and magnesium or unmeasured anions like proteins, phosphorus, sulfates, or other organic acids, the effects of which may not be accurately reflected by the calculated anion gap.

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Antiarrhythmic Drugs: Amiodarone Digoxin, Disopyramide, Flecainide, Lidocaine, Procainamide, Quinidine

A

SYNONYM/ACRONYM: *Amiodarone* (Cordarone); *Digoxin* (Digitek, Lanoxicaps, Lanoxin); *disopyramide* (Norpace, Norpace CR); *flecainide* (flecainide acetate, Tambocor); *lidocaine* (Xylocaine); *procainamide* (Procanbid, Pronestyl, Pronestyl SR); *quinidine* (Quinidex Extentabs, quinidine sulfate SR, quinidine gluconate SR).

COMMON USE: To evaluate specific drugs for subtherapeutic, therapeutic, or toxic levels in treatment of heart failure and cardiac arrhythmias.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

Drug	Route of Administration	Recommended Collection Time
Amiodarone	Oral	Trough: immediately before next dose
Digoxin	Oral	Trough: 12–24 hr after dose Never draw peak samples
Disopyramide	Oral	Trough: immediately before next dose Peak: 2–5 hr after dose
Flecainide	Oral	Trough: immediately before next dose Peak: 3 hr after dose
Lidocaine	IV	15 min, 1 hr, then every 24 hr
Procainamide	IV	15 min; 2, 6, 12 hr; then every 24 hr
Procainamide	Oral	Trough: immediately before next dose Peak: 75 min after dose
Quinidine sulfate	Oral	Trough: immediately before next dose Peak: 1 hr after dose
Quinidine gluconate	Oral	Trough: immediately before next dose Peak: 5 hr after dose
Quinidine polygalacturonate	Oral	Trough: immediately before next dose Peak: 2 hr after dose

NORMAL FINDINGS: (Method: Immunoassay)

Drug (Indication)	Therapeutic Range Conventional Units	Conversion to SI units	SI Units	Half-Life (hr)	Volume of Distribution (L/kg)	Protein Binding (%)	Excretion
Amiodarone	0.5–2.5 mcg/mL	SI units = Conventional Units x 1.55	0.8–3.9 micromol/L	250–1200	20–100	95–97	1° hepatic
Digoxin	0.5–2 ng/mL	SI units = Conventional Units x 1.28	0.6–2.6 nmol/L	20–60	7	20–30	1° renal
Disopyramide	2.8–7 mcg/mL	SI units = Conventional Units x 2.95	8.3–20.6 micromol/L	4–10	0.7–0.9	20–60	1° renal
Flecainide	0.2–1 mcg/mL	SI units = Conventional Units x 2.41	0.5–2.4 micromol/L	7–19	5–13	40–50	1° renal
Lidocaine	1.5–5 mcg/mL	SI units = Conventional Units x 4.27	6.4–21.4 micromol/L	1.5–2	1–1.5	60–80	1° hepatic
Procainamide	4–10 mcg/mL	SI units = Conventional Units x 4.25	17–42 micromol/L	2–6	2–4	10–20	1° renal
N-acetyl procainamide	10–20 mcg/mL	SI units = Conventional Units x 4.25	42–85 micromol/L	8			1° renal
Quinidine	2–5 mcg/mL	SI units = Conventional Units x 3.08	6–15 micromol/L	6–8	2–3	70–90	Renal and hepatic

DESCRIPTION: Cardiac glycosides are used in the prophylactic management and treatment of heart failure and ventricular and atrial arrhythmias. Because these drugs have narrow therapeutic windows, they must be monitored closely. The signs and symptoms of toxicity are often difficult to distinguish from those of cardiac disease. Patients with toxic levels may show gastrointestinal, ocular, and central nervous system effects and disturbances in potassium balance.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient ethnicity, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and the ingestion of substances (e.g., foods, herbals, vitamins, and minerals) that can either potentiate or inhibit the intended target concentration. Peak and trough collection times should be documented carefully in relation to the time of medication administration.

IMPORTANT NOTE: These medications are metabolized and excreted by the liver

POTENTIAL DIAGNOSIS

Level	Response
Normal levels	Therapeutic effect
Subtherapeutic levels	Adjust dose as indicated
Toxic levels	Adjust dose as indicated
Amiodarone	Hepatic impairment, older results
Digoxin	Renal impairment, CHF,* older adults
Disopyramide	Renal impairment
Flecainide	Renal impairment, CHF
Lidocaine	Hepatic impairment, CHF
Procainamide	Renal impairment
Quinidine	Renal and hepatic impairment, CHF, older adults

*CHF = congestive heart failure.

and kidneys and are therefore contraindicated in patients with hepatic or renal disease and cautiously advised in patients with renal impairment. Information regarding medications must be communicated clearly and accurately to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in the calculation of future doses. If administration of the drug is delayed, notify the appropriate department(s) to reschedule the blood draw and notify the requesting health-care provider (HCP) if the delay has caused any real or perceived therapeutic harm.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis and prevention of toxicity
- Monitor compliance with therapeutic regimen
- Monitor patients who have a pacemaker, who have impaired renal or hepatic function, or who are taking interacting drugs

CRITICAL FINDINGS

Adverse effects of subtherapeutic levels are important. Care should be taken to investigate the signs and symptoms of too little and too much medication. Note and immediately report to the HCP any critically increased or subtherapeutic values and related symptoms.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Amiodarone: Greater Than 2.5 mcg/mL (SI: Greater Than 3.9 micromol/L)

Signs and symptoms of pulmonary damage related to amiodarone toxicity include bronchospasm, wheezing, fever, dyspnea, cough, hemoptysis, and hypoxia. Possible interventions include discontinuing the medication, monitoring pulmonary function with chest x-ray, monitoring liver function tests to assess for liver damage, monitoring thyroid function tests to assess for thyroid damage (related to the high concentration of iodine contained in the medication), and

electrocardiographic (ECG) monitoring for worsening of arrhythmia.

Digoxin: Greater Than 2.5 ng/mL (SI: Greater Than 3.2 nmol/L)

Signs and symptoms of digoxin toxicity include arrhythmias, anorexia, hyperkalemia, nausea, vomiting, diarrhea, changes in mental status, and visual disturbances (objects appear yellow or have halos around them). Possible interventions include discontinuing the medication, continuous ECG monitoring (prolonged P-R interval, widening QRS interval, lengthening Q-Tc interval, and atrioventricular block), transcutaneous pacing, administration of activated charcoal (if the patient has a gag reflex and central nervous system function), support and treatment of electrolyte disturbance, and administration of Digibind (digoxin immune Fab). The amount of Digibind given depends on the level of digoxin to be neutralized. Digoxin levels must be measured before the administration of Digibind. Digoxin levels should not be measured for several days after administration of Digibind in patients with normal renal function (1 wk or longer in patients with decreased renal function). Digibind cross-reacts in the digoxin assay and may provide misleading elevations or decreases in values depending on the particular assay in use by the laboratory.

Disopyramide: Greater Than 7 mcg/mL (SI: Greater Than 20.6 micromol/L)

Signs and symptoms of disopyramide toxicity include prolonged Q-T interval, ventricular tachycardia, hypotension, and heart failure. Possible interventions include discontinuing the medication, airway support, and ECG and blood pressure monitoring.

**Flecainide: Greater Than
1 mcg/mL (SI: Greater Than
2.41 micromol/L)**

Signs and symptoms of flecainide toxicity include exaggerated pharmacological effects resulting in arrhythmia. Possible interventions include discontinuing the medication as well as continuous ECG, respiratory, and blood pressure monitoring.

**Lidocaine: Greater Than
6 mcg/mL (SI: Greater Than
25.6 micromol/L)**

Signs and symptoms of lidocaine toxicity include slurred speech, central nervous system depression, cardiovascular depression, convulsions, muscle twitches, and possible coma. Possible interventions include continuous ECG monitoring, airway support, and seizure precautions.

**Procainamide: Greater Than
10 mcg/mL (SI: Greater Than
42.5 micromol/L); N-Acetyl
Procainamide: Greater Than
40 mcg/mL (SI: Greater Than
170 micromol/L)**

The active metabolite of procainamide is *N*-acetyl procainamide (NAPA). Signs and symptoms of procainamide toxicity include torsade de pointes (ventricular tachycardia), nausea, vomiting, agranulocytosis, and hepatic disturbances. Possible interventions include airway protection, emesis, gastric lavage, and administration of sodium lactate.

**Quinidine: Greater Than
6 mcg/mL (SI: Greater Than
18.5 micromol/L)**

Signs and symptoms of quinidine toxicity include ataxia, nausea, vomiting, diarrhea, respiratory system depression, hypotension, syncope, anuria, arrhythmias (heart block,

widening of QRS and Q-T intervals), asystole, hallucinations, paresthesia, and irritability. Possible interventions include airway support, emesis, gastric lavage, administration of activated charcoal, administration of sodium lactate, and temporary transcutaneous or transvenous pacemaker.

INTERFERING FACTORS

- Blood drawn in serum separator tubes (gel tubes).
- Drugs that may increase amiodarone levels include cimetidine.
- Drugs that may decrease amiodarone levels include cholestyramine and phenytoin.
- Drugs that may increase digoxin levels or increase risk of toxicity include amiodarone, amphotericin B, diclofenac, diltiazem, erythromycin, ibuprofen, indomethacin, nifedipine, nisoldipine, propafenone, propantheline, quinidine, spironolactone, tetracycline, tiapamil, troleandomycin, and verapamil.
- Drugs that may decrease digoxin levels include albuterol, aluminum hydroxide (antacids), carbamazepine, cholestyramine, colestipol, digoxin immune Fab, hydralazine, hydroxychloroquine, iron, kaolin-pectin, magnesium hydroxide, magnesium trisilicate, metoclopramide, neomycin, nitroprusside, paroxetine, phenytoin, rifabutin, sulfasalazine, and ticlopidine.
- Drugs that may increase disopyramide levels or increase risk of toxicity include amiodarone, atenolol, ritonavir, and troleandomycin.
- Drugs that may decrease disopyramide levels include phenobarbital, phenytoin, rifabutin, and rifampin.
- Drugs that may increase flecainide levels or increase risk of toxicity include amiodarone and cimetidine.

- Drugs that may decrease flecainide levels include carbamazepine, charcoal, phenobarbital, and phenytoin.
- Drugs that may increase lidocaine levels or increase risk of toxicity include beta blockers, cimetidine, metoprolol, nadolol, propranolol, and ritonavir.
- Drugs that may decrease lidocaine levels include phenytoin.
- Drugs that may increase procainamide levels or increase risk of toxicity include amiodarone, cimetidine, quinidine, ranitidine, and trimethoprim.
- Drugs that may increase quinidine levels or increase risk of toxicity include acetazolamide, amiodarone, cimetidine, itraconazole, mibefradil, nifedipine, nisoldipine, quinidine, ranitidine, thiazide diuretics, and verapamil.
- Drugs that may decrease quinidine levels include kaolin-pectin, ketoconazole, phenobarbital, phenytoin, rifabutin, and rifampin.
- Concomitant administration of amiodarone with other medications may result in toxic levels of the other medications related to the suppression of enzyme activity required to metabolize many other medications by amiodarone. It may also potentiate the anticoagulating effects of warfarin, resulting in increased PT values.
- Digitoxin cross-reacts with digoxin; results are falsely elevated if digoxin is measured when the patient is taking digitoxin.
- Digitalis-like immunoreactive substances are found in the serum of some patients who are not taking digoxin, causing false-positive results. Patients whose serum contains digitalis-like immunoreactive substances usually have a condition related to salt and fluid retention, such as renal failure, hepatic failure, low-renin hypertension, and pregnancy.
- Unexpectedly low digoxin levels may be found in patients with thyroid disease.
- Disopyramide may cause a decrease in glucose levels. It may also potentiate the anticoagulating effects of warfarin, resulting in increased PT values.
- Long-term administration of procainamide can cause false-positive antinuclear antibody results and development of a lupuslike syndrome in some patients.
- Quinidine may potentiate the effects of neuromuscular blocking medications and warfarin anticoagulants.
- Concomitant administration of quinidine and digoxin can rapidly raise digoxin to toxic levels. If both drugs are to be given together, the digoxin level should be measured before the first dose of quinidine and again in 4 to 6 days.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in monitoring for subtherapeutic, therapeutic, or toxic drug levels.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ These medications are metabolized and excreted by the kidneys and liver.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

▸ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

▸ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

▸ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

▸ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

▸ Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to the dosing schedule. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.

▸ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

▸ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

▸ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

▸ **Nutritional Considerations:** Include avoidance of alcohol consumption.

▸ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding drug interactions. Instruct the patient to immediately report any unusual sensations (e.g., dizziness, changes in vision, loss of appetite, nausea, vomiting, diarrhea, weakness, or irregular heartbeat) to his or her HCP. Instruct the patient not to take medicine within 1 hr of food high in fiber (**as the fiber may decrease absorption by binding some of the medication, reducing its bioavailability**). Answer any questions or address any concerns voiced by the patient or family.

▸ Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.

▸ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Testing for aspirin responsiveness/resistance may be a consideration for patients, especially women, on low-dose aspirin therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▸ Related tests include ALT; albumin; ALP; apolipoproteins A, B, and E; AST; atrial natriuretic peptide; BNP; blood gases; BUN; CRP; calcium; calcium ionized; chest x-ray; cholesterol (total, HDL, and LDL); CBC platelet count; CK and isoenzymes; creatinine; ECG; glucose; glycated hemoglobin; homocysteine; ketones; LDH and isoenzymes; magnesium; myoglobin; potassium; triglycerides; and troponin.

▸ See the Cardiovascular System table at the end of the book for related tests by body system.

Antibodies, Anti-Cyclic Citrullinated Peptide

SYNONYM/ACRONYM: Anti-CCP antibodies, ACPA.

COMMON USE: To assist in diagnosing and monitoring rheumatoid arthritis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: IgG Ab (Method: Immunoassay, enzyme-linked immunosorbent assay [ELISA])

Negative	Less than 20 units
Weak positive	20–39 units
Moderate positive	40–59 units
Strong positive	60 units or greater

DESCRIPTION: Rheumatoid arthritis (RA) is a chronic, systemic autoimmune disease that damages the joints. Inflammation caused by autoimmune responses can affect other organs and body systems. The current American Academy of Rheumatology criteria focuses on earlier diagnosis of newly presenting patients who have at least one swollen joint unrelated to another condition. The current criteria includes four determinants: joint involvement (number and size of joints involved), serological test results (rheumatoid factor [RF] and/or ACPA), indications of acute inflammation (CRP and/or ESR), and duration of symptoms. A score of 6 or greater defines the presence of RA. Patients with long-standing RA, whose condition is inactive, or whose prior history would have satisfied the previous classification criteria by having four of seven findings—morning stiffness, arthritis of three or more joint areas, arthritis of hand joints, symmetric arthritis, rheumatoid nodules, abnormal amounts of rheumatoid factor,

and radiographic changes—should remain classified as having RA. The study of RA is complex, and it is believed that multiple genes may be involved in the manifestation of RA. Scientific research has revealed an unusual peptide conversion from arginine to citrulline that results in formation of antibodies whose presence provides the basis for this test. Studies show that detection of antibodies formed against citrullinated peptides is specific and sensitive in detecting RA in both early and established disease. Anti-CCP assays have 96% specificity and 78% sensitivity for RA, compared to the traditional IgM RF marker with a specificity of 60% to 80% and sensitivity of 75% to 80% for RA. Anti-CCP antibodies are being used as a marker for erosive disease in RA, and the antibodies have been detected in healthy patients years before the onset of RA symptoms and diagnosed disease. Some studies have shown that as many as 40% of patients seronegative for RF are anti-CCP positive. The combined

presence of RF and anti-CCP has a 99.5% specificity for RA. Women are two to three times more likely than men to develop RA. Although RA is most likely to affect people aged 35 to 50, it can affect all ages.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of RA in both symptomatic and asymptomatic individuals
- Assist in the identification of erosive disease in RA
- Assist in the diagnostic prediction of RA development in undifferentiated arthritis

POTENTIAL DIAGNOSIS

Increased in

- RA (*The immune system produces antibodies that attack the joint tissues. Inflammation of the synovium, membrane that lines the joint, begins a process called synovitis. If untreated, the synovitis can expand beyond the joint tissue to surrounding ligaments, tissues, nerves, and blood vessels.*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ **Patient Teaching:** Inform the patient this test can assist in identifying the cause of joint inflammation.
- ▶ Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's immune and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting health-care provider (HCP), who will discuss the results with the patient.

- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to anticipated chronic pain resulting from joint inflammation, impairment in mobility, muscular deformity, and perceived loss of independence. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results as appropriate. Explain the importance of physical activity in the treatment plan. Educate the patient regarding access to physical therapy, occupational therapy, and counseling services. Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org) or for the Arthritis Foundation (www.arthritis.org). Encourage the patient to take medications as ordered. Treatment

with disease-modifying antirheumatic drugs (DMARDs) and biologic response modifiers may take as long as 2 to 3 mo to demonstrate their effects.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy.

RELATED MONOGRAPHS:

- ▶ Related tests include ANA, arthroscopy, BMD, bone scan, CBC, CRP, ESR, MRI musculoskeletal, radiography bone, RF, synovial fluid analysis, and uric acid.
- ▶ Refer to the Immune and Musculoskeletal systems tables at the end of the book for related tests by body system.

Antibodies, Anti-Glomerular Basement Membrane

SYNONYM/ACRONYM: Goodpasture's antibody, anti-GBM.

COMMON USE: To assist in differentiating Goodpasture's syndrome (an autoimmune disease) from renal dysfunction.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Lung or kidney tissue also may be submitted for testing. Refer to related biopsy monographs for specimen-collection instructions.

NORMAL FINDINGS: (Method: Enzyme immunoassay) Less than 20 units/mL = negative.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Glomerulonephritis (*of autoimmune origin as evidenced by the presence of anti-GBM antibodies*)

- Goodpasture's syndrome (*related to nephritis of autoimmune origin*)
- Idiopathic pulmonary hemosiderosis

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Antibodies, Actin (Smooth Muscle) and Mitochondrial M2

SYNONYM/ACRONYM: Antiactin antibody, ASMA; mitochondrial M2 antibody, M2 antibody, AMA.

COMMON USE: To assist in the differential diagnosis of chronic liver disease, typically biliary cirrhosis.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Immunoassay, enzyme-linked immunosorbent [ELISA])

Actin smooth muscle antibody, IgG

Negative	Less than 20 units
Weak positive	20–30 units
Positive	Greater than 30 units

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

The exact cause of PBC is unknown. There is a high degree of correlation between the presence of actin smooth muscle antibodies (ASMA) and mitochondrial M2 antibodies (AMA) with PBC, and PBC therefore is thought to be an autoimmune disease. The antibodies have been identified in the sera of patients with other autoimmune diseases.

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Mitochondrial M2 antibody, IgG

Negative	Less than 20 units
Weak positive	20.1–24.9 units
Positive	Greater than 25 units

Actin antibodies (ASMA)

- Autoimmune hepatitis
- Chronic active viral hepatitis
- Infectious mononucleosis
- PBC
- Primary sclerosing cholangitis

Mitochondrial M2 antibodies (AMA)

- Hepatitis (alcoholic, viral)
- PBC
- Rheumatoid arthritis (occasionally)
- Systemic lupus erythematosus (occasionally)
- Thyroid disease (occasionally)

Decreased in: N/A

CRITICAL FINDINGS: N/A

Antibodies, Antineutrophilic Cytoplasmic

SYNONYM/ACRONYM: Cytoplasmic antineutrophil cytoplasmic antibody (c-ANCA), perinuclear antineutrophil cytoplasmic antibody (p-ANCA).

COMMON USE: To assist in diagnosing and monitoring the effectiveness of therapeutic interventions for Wegener's syndrome.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Indirect immunofluorescence) Negative.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

The exact mechanism by which ANCA are developed is unknown. One theory suggests colonization with bacteria capable of expressing microbial superantigens. It is thought that the superantigens may stimulate a strong cellular autoimmune response in genetically susceptible individuals. Another theory suggests the immune system may be stimulated by an accumulation of the antigenic targets of ANCA due to ineffective destruction of old neutrophils or ineffective removal of neutrophil cell fragments containing proteinase,

myeloperoxidase, elastase, lactoferrin, or other proteins.

- c-ANCA
 - WG and its variants
- p-ANCA
 - Alveolar hemorrhage
 - Angiitis and polyangiitis
 - Autoimmune liver disease
 - Capillaritis
 - Churg-Strauss syndrome
 - Crescentic glomerulonephritis
 - Felty's syndrome
 - Glomerulonephritis
 - Inflammatory bowel disease
 - Kawasaki's disease
 - Leukocytoclastic skin vasculitis
 - Microscopic polyarteritis
 - Rheumatoid arthritis
 - Vasculitis

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Antibodies, Antinuclear, Anti-DNA, Anticentromere, Antiextractable Nuclear Antigen, Anti-Jo, and Antiscleroderma

SYNONYM/ACRONYM: Antinuclear antibodies (ANA), anti-DNA (anti-ds DNA), antiextractable nuclear antigens (anti-ENA, ribonucleoprotein [RNP], Smith [Sm], SS-A/Ro, SS-B/La), anti-Jo (antihistidyl transfer RNA [tRNA] synthase), and antiscleroderma (progressive systemic sclerosis [PSS] antibody, Scl-70 antibody, topoisomerase I antibody).

COMMON USE: To diagnose multiple systemic autoimmune disorders; primarily used for diagnosing systemic lupus erythematosus (SLE).

SPECIMEN: Serum (3 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Indirect fluorescent antibody for ANA and anticentromere; Immunoassay multiplex flow for anti-DNA, ENA, Scl-70, and Jo-1)

ANA and anticentromere: Titer of 1:40 or less. Anti-ENA, Jo-1, and anti-Scl-70: Negative. Reference ranges for anti-DNA, anti-ENA, anti-Scl-70, and anti-Jo-1 vary widely due to differences in methods and the testing laboratory should be consulted directly.

Anti-DNA

Negative	Less than 5 international units
Indeterminate	5–9 international units
Positive	Greater than 9 international units

DESCRIPTION: Antinuclear antibodies (ANA) are autoantibodies mainly located in the nucleus of affected cells. The presence of ANA indicates SLE, related collagen vascular diseases, and immune complex diseases.

Antibodies against cellular DNA are strongly associated with SLE. Anticentromere antibodies are a subset of ANA. Their presence is strongly associated with CREST syndrome (*calcinosis, Raynaud's phenomenon, esophageal dysfunction, sclerodactyly, and telangiectasia*). Women are much more likely than men to be diagnosed with SLE. Jo-1 is an autoantibody found in the sera of some ANA-positive patients. Compared to the presence of other autoantibodies, the presence of Jo-1 suggests a more aggressive course and a higher risk of mortality. The clinical effects of this autoantibody include acute onset fever, dry and crackled skin on the hands, Raynaud's phenomenon, and arthritis. The extractable nuclear antigens (ENAs) include ribonucleoprotein (RNP), Smith (Sm), SS-A/Ro, and SS-B/La antigens. ENAs and antibodies to them are

found in various combinations in individuals with combinations of overlapping rheumatologic symptoms. The American College of Rheumatology's current criteria includes a list of 11 signs and/or symptoms to assist in differentiating lupus from similar diseases. The patient should have four or more of these to establish suspicion of lupus; the symptoms do not have to manifest at the same time: malar rash (rash over the cheeks, sometimes described as a butterfly rash), discoid rash (red raised patches), photosensitivity (exposure resulting in development of or increase in skin rash), oral ulcers, nonerosive arthritis involving two or more peripheral joints, pleuritis or pericarditis, renal disorder (as evidenced by excessive protein in urine or the presence of casts in the urine), neurological disorder (seizures or psychosis in the absence of drugs known to cause these effects), hematological disorder (hemolytic anemia, leukopenia, lymphopenia, thrombocytopenia where the leukopenia or lymphopenia occurs on more than two occasions and the thrombocytopenia occurs in

the absence of drugs known to cause it), positive ANA in the absence of a drug known to induce lupus, or immunological disorder (evidenced by positive anti-ds DNA, positive anti-Sm, positive antiphospholipid such as anticardiolipin antibody, positive lupus anticoagulant test, or a false-positive serological syphilis test, known to be positive for at least 6 months and confirmed to be falsely positive by a negative *Treponema pallidum* immobilization or FTA-ABS).

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis and evaluation of SLE
- Assist in the diagnosis and evaluation of suspected immune disorders, such as rheumatoid arthritis, systemic sclerosis, polymyositis, Raynaud's syndrome, scleroderma, Sjögren's syndrome, and mixed connective tissue disease
- Assist in the diagnosis and evaluation of idiopathic inflammatory myopathies

POTENTIAL DIAGNOSIS

ANA Pattern*	Associated Antibody	Associated Condition
Rim and/or homogeneous	Double-stranded DNA	SLE
	Single- or double-stranded DNA	
Homogeneous	Histones	SLE
Speckled	Sm (Smith) antibody	SLE, mixed connective tissue disease, Raynaud's scleroderma, Sjögren's syndrome
	RNP*	Mixed connective tissue disease, various rheumatoid conditions
	SS-B/La, SS-A/Ro	Various rheumatoid conditions
Diffuse speckled with positive mitotic figures	Centromere	PSS with CREST, Raynaud's
Nucleolar	Nucleolar, RNP	Scleroderma, CREST

*ANA patterns are helpful in that certain conditions are frequently associated with specific patterns. RNP = ribonucleoprotein.

Increased in

- Anti-Jo-1 is associated with dermatomyositis, idiopathic inflammatory myopathies, and polymyositis
- ANA is associated with drug-induced lupus erythematosus
- ANA is associated with lupoid hepatitis
- ANA is associated with mixed connective tissue disease
- ANA is associated with polymyositis
- ANA is associated with progressive systemic sclerosis
- ANA is associated with Raynaud's syndrome
- ANA is associated with rheumatoid arthritis
- ANA is associated with Sjögren's syndrome
- ANA and anti-DNA are associated with SLE
- Anti-RNP is associated with mixed connective tissue disease

- Anti-Scl 70 *is associated with progressive systemic sclerosis and scleroderma*
- Anti-SS-A and anti-SS-B *are helpful in antinuclear antibody (ANA)–negative cases of SLE*
- Anti-SS-A/ANA–positive, anti-SS-B–negative patients *are likely to have nephritis*
- Anti-SS-A/anti-SS-B–positive sera *are found in patients with neonatal lupus*
- Anti-SS-A–positive patients *may also have antibodies associated with antiphospholipid syndrome*
- Anti-SS-A/La *is associated with primary Sjögren’s syndrome*
- Anti-SS-A/Ro *is a predictor of congenital heart block in neonates born to mothers with SLE*
- Anti-SS-A/Ro–positive patients *have photosensitivity*

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may cause positive ANA results include acebutolol (diabetics), anticonvulsants (increases with concomitant administration of multiple antiepileptic drugs), carbamazepine, chlorpromazine, ethosuximide, hydralazine, isoniazid, methyl dopa, oxyphenisatin, penicillins, phenytoin, primidone, procainamide, quinidine, and trimethadione.
- A patient can have lupus and test ANA-negative.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status may interfere with the test results.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs and Symptoms	Interventions
Noncompliance, risk (<i>Related to failure to comply with recommended therapeutic interventions; failure to accept diagnosis</i>)	Triggering an acute episode of lupus due to excessive sun exposure during peak periods	Ensure the patient understands the diagnosis and disease process; discuss the risks of noncompliance on overall health
Skin (<i>Related to rash and lesions associated with the disease process</i>)	Butterfly rash across bridge of nose; lesions on exposed areas of the skin; nose and mouth ulcers	Avoid sun exposure during high-UV times; use a sunscreen with a UV protection greater than SPF 15 with sun exposure; reapply sunscreen frequently as needed; applies therapeutic creams or ointments to skin as prescribed by the physician

(table continues on page 126)

Problem	Signs and Symptoms	Interventions
Protection <i>(Related to open sores; decreased immune response; steroid use)</i>	Fever; tenderness, redness, warmth, drainage, and swelling of open sores	Vigilant hand hygiene to protect from infection; monitor temperature and report any fever; monitor open sores for signs of infection; monitor white blood count; reverse isolation if immune system is compromised; adequate nutrition to promote healing
Body image <i>(Related to physical changes associated with the disease process)</i>	Chronic erythematous coin-shaped raised patches (plaque) with scarring from older lesions; fixed erythema, flat or raised rash over the bridge of the nose and the cheekbones; expressions of feelings or concerns over visual physical changes; fear of rejection by others due to appearance	Emphasize strengths; determine the patient's expectations regarding appearance; identify the influence of the patient's culture, religion, race, and gender on body image perceptions; monitor verbalization of self-criticism

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating immune system function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Collagen and connective tissue diseases are chronic and, as such, they must be addressed on a continuous basis. Discuss the implications of abnormal test results on the patient's lifestyle. Stress the importance of compliance to the treatment regimen. Instruct the patient with SLE to contact the HCP immediately if new symptoms present, including vague or common symptoms such as fever. Educate the patient regarding lifestyle changes that must be implemented to protect them from increased risk of infection and development of cardiovascular disease. Patients with lupus should be advised to avoid direct exposure to sunlight or other sources of UV light, like tanning beds (**related to hypersensitivity of skin cells in people with lupus to UV light. The exact mechanism for this is not clearly understood, but it is believed that in people with lupus, damaged or dead skin cells are not sloughed as efficiently as occurs in normal individuals. It is also believed that cell contents released from damaged or dead skin cells may instigate an immune response leading to development of a skin rash. Sun exposure is known to damage skin; therefore, avoiding direct exposure reduces the amount of damage incurred.**).
- ▶ Patients wishing to become pregnant should discuss the possibility with their HCP. The stress of pregnancy and medication regimen may present significant risks to both mother and

child; pregnancies should be carefully planned.

- ▶ Patients with lupus are at increased risk for infection and should discuss the need for vaccinations with their HCP. Recommendations may include receiving vaccines during periods of remission.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Educate the patient regarding access to counseling services.
- ▶ Educate the patient, as appropriate, regarding the importance of preventing infection, which is a significant cause of death in immunosuppressed individuals.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org), the Lupus Foundation of America (www.lupus.org), or the Arthritis Foundation (www.arthritis.org).
- ▶ Provide education on caring for open sores to prevent infection.
- ▶ Discuss the importance of adequate nutrients in supporting the immune system and preventing infection.

Expected Patient Outcomes:

Knowledge

- ▶ Describes the relationship between sun exposure and triggering an acute lupus episode
- ▶ Explains that wearing loose, long-leg and long-sleeve clothing can enhance sun protection

Skills

- ▶ Routinely demonstrates good hand hygiene skills
- ▶ Demonstrates proficiency in the correct application of sunscreen

Attitude

- Identifies personal strengths to enhance self-esteem
- Discusses change in appearance in a positive manner

RELATED MONOGRAPHS:

- Related tests include antibodies anticyclic citrullinated peptide, arthroscopy, biopsy kidney, biopsy skin, BMD,

bone scan, chest x-ray, complement C3 and C4, complement total, CRP, creatinine, ESR, EMG, MRI musculoskeletal, procainamide, radiography bone, RF, synovial fluid analysis, and UA.

- See the Immune and Musculoskeletal systems tables at the end of the book for related tests by body system.

Antibodies, Antisperm

SYNONYM/ACRONYM: Infertility screen.

COMMON USE: To evaluate testicular fertility and identify causes of infertility such as congenital defects, cancer, and torsion.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

Result	Sperm Bound by Immunobead (%)
Negative	0–15
Weak positive	16–30
Moderate positive	31–50
Strong positive	51–100

DESCRIPTION: Normally sperm develop in the seminiferous tubules of the testes separated from circulating blood by the blood-testes barrier. Any situation that disrupts this barrier can expose sperm to detection by immune response cells in the blood and subsequent antibody formation against the sperm. Antisperm antibodies attach to the head, midpiece, or tail of the sperm, impairing motility and ability to penetrate the cervical mucosa. The antibodies can also cause clumping of sperm, which may be noted on a semen analysis.

A major cause of infertility in men is blocked efferent testicular ducts. Reabsorption of sperm from the blocked ducts may also result in development of sperm antibodies. Another more specific and sophisticated method than measurement of circulating antibodies is the immunobead sperm antibody test used to identify antibodies directly attached to the sperm. Semen and cervical mucus can also be tested for antisperm antibodies.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluation of infertility

POTENTIAL DIAGNOSIS**Increased in**

Conditions that affect the integrity of the blood-testes barrier can result in antibody formation.

- Blocked testicular efferent duct (*related to absorption of sperm by blocked vas deferens*)
- Congenital absence of the vas deferens (*related to absorption of sperm by blocked vas deferens*)
- Cryptorchidism (*related to disruption in the integrity of the blood-testes barrier*)
- Infection (orchitis, prostatitis) (*related to disruption in the integrity of the blood-testes barrier*)
- Inguinal hernia repair prior to puberty (*related to disruption in the integrity of the blood-testes barrier*)
- Testicular biopsy (*related to disruption in the integrity of the blood-testes barrier*)
- Testicular cancer (*related to disruption in the integrity of the blood-testes barrier*)
- Testicular torsion (*related to disruption in the integrity of the blood-testes barrier*)
- Varicocele (*related to disruption in the integrity of the blood-testes barrier*)
- Vasectomy (*related to absorption of sperm by blocked vas deferens*)
- Vasectomy reversal (*related to interaction between sperm and autoantibodies developed after vasectomy*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- The patient should not ejaculate for 3 to 4 days before specimen collection if semen will be evaluated; results may be affected if specimens are collected within 48 hr of ejaculating or after no ejaculation for longer than 5 days.
- Sperm antibodies have been detected in pregnant women and in women with primary infertility.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs and Symptoms	Interventions
Sexuality (<i>Related to altered sexual activity; diminished intimacy; testicular disease</i>)	Decreased sexual satisfaction; diminished sexual function; ongoing infertility	Discuss the possibility of sperm banking for future fertility needs; suggest counseling for patient and family and provide contact information; facilitate a discussion of realistic changes to sexual intimacy associated with testicular disease; provide a relaxed atmosphere to discuss sexuality concerns; provide contact information for a support group
Self-esteem (<i>Related to altered view of self secondary to altered ability to participate in</i>)	Verbalizes feelings that express being a failure as a man; dissatisfaction with present state of intimacy with significant other	Monitor for negative self-statements; assess for withdrawal; monitor for real or perceived rejection of others; encourage verbalization of self-worth; encourage a discussion of perceived changes in family role;

(table continues on page 130)

Problem	Signs and Symptoms	Interventions
<p><i>sexual intimacy; infertility; altered body image)</i></p> <p>Fear (<i>Related to prognosis secondary to diagnosis (cancer); infertility; permanently altered sexual function; risk of death; loss of control; ineffective coping; unfamiliar therapeutic regime; unknown)</i></p>	<p>Expression of fear; preoccupation with fear; increased tension; increased blood pressure; increased heart rate; vomiting; diarrhea; nausea; fatigue; weakness; insomnia; shortness of breath; increased respiratory rate; withdrawal; panic attacks</p>	<p>monitor for anxiety; recommend personal and family counseling; facilitate support group participation</p> <p>Discuss the concepts of watchful waiting, surgical intervention, radiation therapy, chemotherapy, in relation to diagnosis; access social services; provide specific and culturally appropriate education; assist the patient and family to recognize effective coping strategies; assist the patient to acknowledge fear; provide a safe environment to decrease fear; explore cultural influences that may enhance fear; utilize therapeutic touch as appropriate to decrease fear; collaborate with social services to address specific medical problems associated with fear</p>
<p>Pain (<i>Related to spermatic cord twisting; disease process (cancer); infection)</i></p>	<p>Sudden testicular pain; swollen tender testicle; nausea; bloody semen; visually one testicle is higher than the other; testicular lumps; achy discomfort in the lower abdomen; self-report of pain; crying; moaning; sleeplessness; restlessness; emotional symptoms of distress; agitation; facial grimace; irritability; diaphoresis; altered blood pressure and heart rate; nausea; vomiting</p>	<p>Assess pain characteristics, testicular, low abdomen; identify pain modalities that have relieved pain in the past; administer prescribed pain medication; monitor and trend vital signs; recommend use of nonpharmacologic pain management modalities, imagery, distraction, music, relaxation; provide education on postoperative pain management</p>

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in the evaluation of

infertility and provide guidance through assistive reproductive techniques.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that blood specimen collection takes approximately 5 to 10 min and that additional specimens may be required. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Timing of specimen collection is an important instruction to follow in order to obtain accurate results if semen will be evaluated. The testing facility should be contacted for specific instructions that the patient will need to follow for specimen collection and direct, timely submission to the testing facility.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Educate the patient regarding access to counseling services. Provide a supportive, nonjudgmental environment when assisting a patient through the process of fertility testing.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Educate the patient regarding access to counseling services, as appropriate.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding of therapeutic options as described by HCP
- ▶ States understanding that infertility may be permanent

Skill

- ▶ Actively participates in a support group to address fertility concerns
- ▶ Describes postoperative symptoms of infection that should be reported to the HCP

Attitude

- ▶ Complies with recommendation to attend support group
- ▶ Complies with the recommendation to attend personal and family counseling in relation to changes in intimacy and fertility.

RELATED MONOGRAPHS:

- ▶ Related tests include HCG, LH, progesterone, semen analysis, testosterone, and US scrotal.
- ▶ See the Reproductive System tables at the end of the book for related tests by body system.

Antibodies, Antistreptolysin O

SYNONYM/ACRONYM: Streptozyne, ASO.

COMMON USE: To assist in the diagnosis of streptococcal infection.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Immunoturbidimetric) Adult/older adult: Less than 200 international units/mL; 17 yr and younger: Less than 150 international units/mL.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Presence of antibodies, especially a rise in titer, is indicative of exposure.

- Endocarditis
- Glomerulonephritis
- Rheumatic fever
- Scarlet fever

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Antibodies, Antithyroglobulin, and Antithyroid Peroxidase

SYNONYM/ACRONYM: Thyroid antibodies, antithyroid peroxidase antibodies (thyroid peroxidase [TPO] antibodies were previously called thyroid anti-microsomal antibodies).

COMMON USE: To assist in diagnosing hypothyroid and hyperthyroid disease.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

Antibody	Conventional Units
Antithyroglobulin antibody	Less than 20 international units/mL
Antiperoxidase antibody	
Newborn–3 days	0–9 international units/mL
4–30 days	0–26 international units/mL
1–12 mo	0–13 international units/mL
13 mo–19 yr	0–20 international units/mL
20 yr–older adult	0–34 international units/mL

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

The presence of these antibodies differentiates the autoimmune origin of these disorders from non-autoimmune causes, which may influence treatment decisions.

- Autoimmune disorders
- Graves' disease
- Goiter
- Hashimoto's thyroiditis
- Idiopathic myxedema
- Pernicious anemia
- Thyroid carcinoma

Decreased in: N/A

Low-medium positive:

20–80 MPL

Greater than 80 MPL

DESCRIPTION: Anticardiolipin (ACA) is one of several identified antiphospholipid antibodies. ACAs are of IgG, IgM, and IgA subtypes, which react with proteins in the blood that are bound to phospholipid and inter-

fere with normal blood vessel function. The two primary types of problems they cause are narrowing and irregularity of the blood vessels and blood clots in the blood vessels. ACAs are found in individuals with

lupus erythematosus, lupus-related conditions, infectious diseases, drug reactions, and sometimes fetal loss. ACAs are often found in association with lupus anticoagulant. Increased antiphospholipid antibody levels have been found in pregnant women with lupus who have had miscarriages. β_2 Glycoprotein 1, or apolipoprotein H, is an important facilitator in the binding of antiphospholipid antibodies like ACA. A normal level of β_2 glycoprotein 1 is 19 units or less when measured by ELISA assays.

β_2 Glycoprotein 1 measurements are considered to be more specific than ACA because they do not demonstrate nonspecific reactivity as do ACA in sera of patients with syphilis or other infectious diseases. The combination of noninflammatory thrombosis of blood vessels, low platelet count, and history of miscarriage is termed *antiphospholipid antibody syndrome* and is documented as present if at least one of the clinical and one of the laboratory criteria are met.

Clinical criteria

- Vascular thrombosis confirmed by histopathology or imaging studies
- Pregnancy morbidity defined as either one or more unexplained deaths of a morphologically normal fetus at or beyond the 10th week of gestation
- One or more premature births of a morphologically normal neonate before the 34th week of gestation due to eclampsia or severe pre-eclampsia
- Three or more unexplained consecutive spontaneous abortions before the 10th week of gestation
- Laboratory criteria (all measured by a standardized ELISA, according to recommended procedures)

- ACA IgG, or IgM, detectable at greater than 40 units on two or more occasions at least 12 wk apart
- Lupus anticoagulant (LA) detectable on two or more occasions at least 12 wk apart
- Anti- β_2 glycoprotein 1 antibody, IgG, or IgM detectable on two or more occasions at least 12 wk apart

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of antiphospholipid antibody syndrome

POTENTIAL DIAGNOSIS

Increased in

While ACAs are observed in specific diseases, the exact mechanism of these antibodies in disease is unclear. In fact, the production of ACA can be induced by bacterial, treponemal, and viral infections. Development of ACA under this circumstance is transient and not associated with an increased risk of antiphospholipid antibody syndrome. Patients who initially demonstrate positive ACA levels should be retested after 6 to 8 wk to rule out transient antibodies that are usually of no clinical significance.

- Antiphospholipid antibody syndrome
- Chorea
- Drug reactions
- Epilepsy
- Infectious diseases
- Mitral valve endocarditis
- Patients with lupuslike symptoms (often antinuclear antibody–negative)
- Placental infarction
- Recurrent fetal loss (strong association with two or more occurrences)
- Recurrent venous and arterial thromboses
- SLE

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase anticardiolipin antibody levels include chlorpromazine, penicillin,

procainamide, phenytoin, and quinidine.

- Cardiolipin antibody is partially cross-reactive with syphilis reagin antibody and lupus anticoagulant. False-positive rapid plasma reagin results may occur.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs and Symptoms	Interventions
Fear (<i>Related to possible loss of potential child; disability; death</i>)	Verbalization of fear; restlessness; increased tension; continuous questioning; increased blood pressure, heart rate, respiratory rate	Provide specific and culturally appropriate education; assist the patient and family to recognize effective coping strategies; assist the patient to acknowledge fear; provide a safe environment to decrease fear; explore cultural influences that may enhance fear; utilize therapeutic touch as appropriate to decrease fear; collaborate with social services to address specific medical problems associated with fear
Grief (<i>Related to placental infarction associated with placental cell death resulting in loss of potential child</i>)	Apparent psychological and emotional distress; withdrawal; detachment; loss of appetite; refusal to participate in activities of daily living; anger; blame	Assess decision-making ability; encourage expression of grief; provide contact information for grief support group; assist to identify current support group; provide social services referral as appropriate; allow the patient to recall the loss and express feelings
Spirituality (<i>Related to significant loss; fear of death; debilitation disease process</i>)	Forgiveness; acceptance; anger at spiritual leaders; expressed feelings of hopeless, powerlessness; abandonment; refusals or inability to participate in spiritual activities (prayer); expresses feelings over lack of meaning with life or serenity	Encourage the verbalization of feelings in a safe nonjudgmental environment; assess the desire for contact from associated spiritual leader; foster a supportive relationship with the patient and family; encourage a display of objects (spiritual, religious) that provide emotional relief; assess for expressions of hope

Problem	Signs and Symptoms	Interventions
Family process (<i>Related to altered role performance secondary to disease progression</i>)	Inability to perform in supportive family role; alteration in family finances; change in communication patterns; change in the assignment of family tasks and the performance of those tasks; alterations in intimacy	Family counseling; facilitating opportunities for the patient and family to express their feelings; assess the patient and family perception of the problems; evaluate patient and family weaknesses, strengths, and coping strategies; help the family and patient break down concerns into manageable parts

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating the amount of potentially harmful circulating antibodies.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic, immune, and reproductive systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has

a history of allergic reaction to latex.

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the Lupus Foundation of America (www.lupus.org).

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- States understanding that fetal loss may be associated with placental infarct.
- States understanding of the importance in identifying a support system that can assist with coping with the spiritual distress of grief and loss.

Skills

- Attends recommended grief counseling for emotional and psychological support related to fetal loss.
- Actively participates in the provision of self-care associated with the activities of daily living.

Attitude

- Seeks assistance from spiritual leader to relieve emotional distress associated with loss of potential child, or loss of function secondary to disease process.
- Agrees to listen to the designated spiritual leader to assist in decreasing grief, loss.

RELATED MONOGRAPHS:

- Related tests include ANA, CBC, CBC platelet count, fibrinogen, lupus anticoagulant antibodies, protein C, protein S, and syphilis serology.
- See the Hematopoietic, Immune, and Reproductive systems tables at the end of the book for related tests by body system.

Antibodies, Gliadin (Immunoglobulin G and Immunoglobulin A), Endomysial (Immunoglobulin A), Tissue Transglutaminase (Immunoglobulin A)

SYNONYM/ACRONYM: Endomysial antibodies (EMA), gliadin deamidated peptide (IgG and IgA) antibodies, tTG.

COMMON USE: To assist in the diagnosis and monitoring of gluten-sensitive enteropathies that may damage intestinal mucosa.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Enzyme linked immunosorbent assay [ELISA] for gliadin antibody and tissue transglutaminase antibody; indirect immunofluorescence for endomysial antibodies)

Conventional Units

IgA and IgG Gliadin Antibody	Less than 20 units
Tissue transglutaminase antibody	Less than 20 units
Endomysial antibodies	Negative

DESCRIPTION: Gliadin is a water-soluble protein found in the gluten of wheat, rye, oats, and barley. The intestinal mucosa of certain individuals does not digest gluten, allowing a toxic buildup of gliadin and intestinal inflammation. The inflammatory response interferes with intestinal absorption of nutrients and damages the intestinal mucosa. In severe cases, intestinal mucosa can be lost. Immunoglobulin G (IgG) and immunoglobulin A (IgA) gliadin antibodies are detectable in the serum of patients with gluten-sensitive enteropathy. Endomysial antibodies and tissue transglutaminase (tTG) antibody are two other serological tests commonly used to investigate gluten-sensitive enteropathies. Gliadin IgA tests are the most sensitive for celiac disease (CD). However, it is also recognized that a significant percentage of patients with CD are also IgA deficient, meaning false-negative IgA results may be misleading in some cases. Estimates of up to 98% of individuals susceptible to CD carry either the DQ2 or DQ8 HLA cell surface receptors, which initiate formation of antibodies to gliadin. While it appears there is a strong association between CD and these gene markers, up to 40% of individuals without CD also carry the DQ2 or DQ8 markers. Molecular testing is available to establish the absence or presence of these susceptibility markers. CD is an inherited condition with significant impact on quality of life for the affected individual. The use of serological markers is useful in disease monitoring because research has established a relationship between amount of gluten in the diet and degree of

intestinal damage as reflected by the level of detectable antibodies. CD shares an association with a number of other conditions such as type 1 diabetes, Down's syndrome, and Turner's syndrome.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of asymptomatic gluten-sensitive enteropathy in some patients with dermatitis herpetiformis
- Assist in the diagnosis of gluten-sensitive enteropathies
- Assist in the diagnosis of nontropical sprue
- Monitor dietary compliance of patients with gluten-sensitive enteropathies

POTENTIAL DIAGNOSIS

Increased in

Evidenced by the combination of detectable gliadin or endomysial antibodies and improvement with a gluten-free diet.

- Asymptomatic gluten-sensitive enteropathy
- Celiac disease
- Dermatitis herpetiformis (*etiology of this skin manifestation is unknown, but there is an association related to gluten-sensitive enteropathy*)
- Nontropical sprue

Decreased in

- IgA deficiency (*related to an inability to produce IgA and evidenced by decreased IgA levels and false-negative IgA gliadin tests*)
- Children under the age of 18 mo (*related to immature immune system and low production of IgA*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Conditions other than gluten-sensitive enteropathy can result in elevated antibody levels without corresponding histological evidence. These conditions include Crohn's disease, postinfection malabsorption, and food protein intolerance.
- A negative IgA gliadin result, especially with a positive IgG gliadin result in an untreated patient, does not rule out active gluten-sensitive enteropathy.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with evaluating the ability to digest gluten foods such as wheat, rye, and oats.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of foods and the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Encourage the patient with abnormal findings to consult with a qualified nutritionist to plan a gluten-free diet. This dietary planning is complex because patients are often malnourished and have other related nutritional problems.
- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to appropriate counseling services. Provide contact information, if desired, for the Celiac Disease Foundation (www.celiac.org) or Children's Digestive Health and Nutrition Foundation (www.cdhnf.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address

any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include albumin, biopsy intestine, biopsy skin, calcium, capsule endoscopy, colonoscopy, D-xylose tolerance test, electrolytes, fecal analysis, fecal fat, folic acid, immunoglobulins (IgA), iron, and lactose tolerance test.
- See the Gastrointestinal and Immune systems tables at the end of the book for related tests by body system.

Anticonvulsant Drugs: Carbamazepine, Ethosuximide, Lamotrigine, Phenobarbital, Phenytoin, Primidone, Valproic Acid

SYNONYM/ACRONYM: *Carbamazepine* (Carbamazepinum, Carbategretal, Carbazol, Carbazep, CBZ, Epitol, Tegretol, Tegretol XR); *ethosuximide* (Suxinutin, Zarontin, Zartalin); *lamotrigine* (Lamictal) *phenobarbital* (Barbita, Comizial, Fenilcal, Gardenal, Phenemal, Phenemalum, Phenobarb, Phenobarbitone, Phenylethylmalonylurea, Solfoton, Stental Extentabs); *phenytoin* (Antisacer, Dilantin, Dintoina, Diphenylan Sodium, Diphenylhydantoin, Ditan, Epanutin, Epinat, Fenitoina, Fenytoin, Fosphenytoin); *primidone* (Desoxyphenobarbital, Hexamidinum, Majsolin, Mylepsin, Mysoline, Primaclone, Prysolin); *valproic acid* (Depacon, Depakene, Depakote, Depakote XR, Depamide, Dipropylacetic Acid, Divalproex Sodium, Epilim, Ergenyl, Leptilan, 2-Propylpentanoic Acid, 2-Propylvaleric Acid, Valkote, Valproate Semisodium, Valproate Sodium).

COMMON USE: To monitor specific drugs for subtherapeutic, therapeutic, or toxic levels in evaluation of treatment.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

Drug*	Route of Administration
Carbamazepine	Oral
Ethosuximide	Oral
Lamotrigine	Oral
Phenobarbital	Oral
Phenytoin	Oral
Primidone	Oral
Valproic acid	Oral

*Recommended collection time = trough: immediately before next dose (at steady state) or at a consistent sampling time.

NORMAL FINDINGS: (Method: Immunoassay for all except lamotrigine; liquid chromatography/tandem mass spectrometry for lamotrigine)

Drug	Therapeutic Range Conventional Units	Conversion to SI units	Therapeutic Range SI Units	Half-Life (hr)	Volume of Distribution (L/kg)	Protein Binding (%)	Excretion
Carbamazepine	4–12 mcg/mL	SI units = Conventional Units x 4.23	17–51 micromol/L	15–40	0.8–1.8	60–80	Hepatic
Ethosuximide	40–100 mcg/mL	SI units = Conventional Units x 7.08	283–708 micromol/L	25–70	0.7	0–5	Renal
Lamotrigine	1–4 mcg/mL	SI units = Conventional Units x 3.9	4–16 micromol/L	25–33	0.9–1.3	50–5	Hepatic
Phenobarbital	Adult: 15–40 mcg/mL Child: 15–30 mcg/mL	SI units = Conventional Units x 4.31	Adult: 65–172 micromol/L Child: 65–129 micromol/L	Adult: 50–140 Child: 40–70	0.5–1	40–50	80% Hepatic and 20% Renal
Phenytoin	10–20 mcg/mL	SI units = Conventional Units x 3.96	40–79 micromol/L	20–40	0.6–0.7	85–95	Hepatic and 20% Renal
Primidone	Adult: 5–12 mcg/mL Child: 7–10 mcg/mL	SI units = Conventional Units x 4.58	Adult: 23–55 micromol/L Child: 32–46 micromol/L	4–12	0.5–1	0–20	Hepatic
Valproic acid	50–125 mcg/mL	SI units = Conventional Units x 6.93	347–866 micromol/L	8–15	0.1–0.5	85–95	Hepatic

DESCRIPTION: Anticonvulsants are used to reduce the frequency and severity of seizures for patients with epilepsy. Carbamazepine is also used for controlling neurogenic pain in trigeminal neuralgia and diabetic neuropathy and for treating bipolar disease and other neurological and psychiatric conditions. Valproic acid is also used for some psychiatric conditions like bipolar disease and for prevention of migraine headache.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and the ingestion of substances (e.g., foods, herbals, vitamins, and minerals) that can either potentiate or inhibit the intended target concentration. Peak and trough collection times should be documented carefully in relation to the time of medication administration.

The metabolism of many commonly prescribed medications is driven by the cytochrome P450 (CYP450) family of enzymes. Genetic variants can alter enzymatic activity that results in a spectrum of effects ranging from the total absence of drug metabolism to ultrafast metabolism. Impaired drug metabolism can prevent the intended therapeutic effect or even lead to serious adverse drug reactions. Poor metabolizers (PM) are at increased risk for drug-induced side effects due to accumulation of drug in the blood, while ultra-rapid metabolizers (UM) require a higher than normal dosage because the drug is metabolized over a shorter duration than intended. In the case of pro-drugs, which require

activation prior to metabolism, the opposite occurs: PM may require a higher dose because the activated drug becomes available more slowly than intended, and UM requires less because the activated drug becomes available sooner than intended. Other genetic phenotypes used to report CYP450 results are intermediate metabolizer (IM) and extensive metabolizer (EM). Genetic testing can be performed on blood samples submitted to a laboratory. The test method commonly used is polymerase chain reaction. Counseling and informed written consent are generally required for genetic testing. CYP2C9 is a gene in the CYP450 family that metabolizes pro-drugs like phenytoin as well as other drugs like phenobarbital; the anti-coagulant warfarin; and opioid analgesics like codeine, hydrocodone, dihydrocodeine, oxycodone, and tramadol. Testing for the most common genetic variants of CYP2C9 is used to predict altered enzyme activity and anticipate the most effective therapeutic plan. Incidence of the PM phenotype is estimated to be less than 0.04% of African Americans and less than 0.1% of Caucasians and Asians.

IMPORTANT NOTE

These medications are metabolized and excreted by the liver and kidneys and are therefore contraindicated in patients with hepatic or renal disease. Caution is advised for patients with renal impairment. Information regarding medications must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause

of subtherapeutic levels, toxic levels, and misleading information used in calculation of future doses. If administration of the drug is delayed, notify the appropriate department(s) to reschedule the blood draw and notify the requesting health-care provider (HCP) if the delay has caused any real or perceived therapeutic harm.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of and prevention of toxicity
- Evaluate overdose, especially in combination with ethanol
- Monitor compliance with therapeutic regimen

POTENTIAL DIAGNOSIS

Level	Response
Normal levels	Therapeutic effect
Subtherapeutic levels	Adjust dose as indicated
Toxic levels	Adjust dose as indicated
Carbamazepine	Hepatic impairment
Ethosuximide	Renal impairment
Lamotrigine	Hepatic impairment
Phenobarbital	Hepatic or renal impairment
Phenytoin	Hepatic impairment
Primidone	Hepatic impairment
Valproic acid	Hepatic impairment

CRITICAL FINDINGS

It is important to note the adverse effects of toxic and subtherapeutic levels. Care must be taken to investigate

signs and symptoms of not enough medication and too much medication. Note and immediately report to the HCP any critically increased or subtherapeutic values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Carbamazepine: Greater Than 20 mcg/mL (SI: Greater Than 85 micromol/L)

Signs and symptoms of carbamazepine toxicity include respiratory depression, seizures, leukopenia, hyponatremia, hypotension, stupor, and possible coma. Possible interventions include gastric lavage (contraindicated if ileus is present); airway protection; administration of fluids and vasopressors for hypotension; treatment of seizures with diazepam, phenobarbital, or phenytoin; cardiac monitoring; monitoring of vital signs; and discontinuing the medication. Emetics are contraindicated.

Ethosuximide: Greater Than 200 mcg/mL (SI: Greater Than 1,416 micromol/L)

Signs and symptoms of ethosuximide toxicity include nausea, vomiting, and lethargy. Possible interventions include administration of activated charcoal, administration of saline cathartic and gastric lavage (contraindicated if ileus is present), airway protection, hourly assessment of neurologic function, and discontinuing the medication.

Lamotrigine: Greater Than 20 mcg/mL (SI: Greater Than 78 micromol/L)

Signs and symptoms of lamotrigine toxicity include severe skin rash, nausea, vomiting, ataxia, decreased levels of consciousness, coma, increased seizures, nystagmus. Possible interventions include administration of activated charcoal, administration of saline cathartic and gastric lavage (contraindicated if ileus is present), airway protection, hourly assessment of neurologic function, and discontinuing the medication.

Phenobarbital: Greater Than 60 mcg/mL (SI: Greater Than 259 micromol/L)

Signs and symptoms of phenobarbital toxicity include cold, clammy skin; ataxia; central nervous system (CNS) depression; hypothermia; hypotension; cyanosis; Cheyne-Stokes respiration; tachycardia; possible coma; and possible renal impairment. Possible interventions include gastric lavage, administration of activated charcoal with cathartic, airway protection, possible intubation and mechanical ventilation (especially during gastric lavage if there is no gag reflex), monitoring for hypotension, and discontinuing the medication.

Phenytoin (Adults): Greater Than 40 mcg/mL (SI: Greater Than 158 micromol/L)

Signs and symptoms of phenytoin toxicity include double vision, nystagmus,

lethargy, CNS depression, and possible coma. Possible interventions include airway support, electrocardiographic monitoring, administration of activated charcoal, gastric lavage with warm saline or tap water, administration of saline or sorbitol cathartic, and discontinuing the medication.

Primidone: Greater Than 15 mcg/mL (SI: Greater Than 69 micromol/L)

Signs and symptoms of primidone toxicity include ataxia, anemia, CNS depression, lethargy, somnolence, vertigo, and visual disturbances. Possible interventions include airway protection, treatment of anemia with vitamin B₁₂ and folate, and discontinuing the medication.

Valproic Acid: Greater Than 200 mcg/mL (SI: Greater Than 1,386 micromol/L)

Signs and symptoms of valproic acid toxicity include loss of appetite, mental changes, numbness, tingling, and weakness. Possible interventions include administration of activated charcoal and naloxone and discontinuing the medication.

INTERFERING FACTORS

- Blood drawn in serum separator tubes (gel tubes).
- Drugs that may increase carbamazepine levels or increase risk of toxicity include acetazolamide, azithromycin, bepridil, cimetidine, danazol, diltiazem, erythromycin, felodipine, fluoxetine, flurithromycin, fluvoxamine, gemfibrozil, isoniazid, itraconazole, josamycin, ketoconazole, loratadine, macrolides, niacinamide, nicardipine, nifedipine, nimodipine, nisoldipine, propoxyphene, ritonavir, terfenadine, troleandomycin, valproic acid, verapamil, and viloxazine.
- Drugs that may decrease carbamazepine levels include phenobarbital, phenytoin, and primidone.

- Carbamazepine may affect other body chemistries as seen by a decrease in calcium, sodium, T_3 , T_4 levels, and WBC count and increase in ALT, alkaline phosphatase, ammonia, AST, and bilirubin levels.
- Drugs that may increase ethosuximide levels include isoniazid, ritonavir, and valproic acid.
- Drugs that may decrease ethosuximide levels include phenobarbital, phenytoin, and primidone.
- Drugs that may increase lamotrigine levels include valproic acid.
- Drugs that may decrease lamotrigine levels include acetaminophen, carbamazepine, hydantoin (e.g., phenytoin), oral contraceptives, orlistat, oxcarbazepine, phenobarbital, primidone, protease inhibitors (e.g., ritonavir), rifamycins (e.g., rifampin), and succinimides (e.g., ethosuximide).
- Drugs that may increase phenobarbital levels or increase risk of toxicity include barbituric drugs, furosemide, primidone, salicylates, and valproic acid.
- Phenobarbital may affect the metabolism of other drugs, increasing their effectiveness, such as β -blockers, chloramphenicol, corticosteroids, doxycycline, griseofulvin, haloperidol, methylphenidate, phenothiazines, phenylbutazone, propoxyphene, quinidine, theophylline, tricyclic antidepressants, and valproic acid.
- Phenobarbital may affect the metabolism of other drugs, decreasing their effectiveness, such as chloramphenicol, cyclosporine, ethosuximide, oral anticoagulants, oral contraceptives, phenytoin, theophylline, vitamin D, and vitamin K.
- Phenobarbital is an active metabolite of primidone, and both drug levels should be monitored while the patient is receiving primidone to avoid either toxic or subtherapeutic levels of both medications.
- Phenobarbital may affect other body chemistries as seen by a decrease in bilirubin and calcium levels and increase in alkaline phosphatase, ammonia, and gamma glutamyl transferase levels.
- Drugs that may increase phenytoin levels or increase the risk of phenytoin toxicity include amiodarone, azapropazone, carbamazepine, chloramphenicol, cimetidine, disulfiram, ethanol, fluconazole, halothane, ibuprofen, imipramine, levodopa, metronidazole, miconazole, nifedipine, phenylbutazone, sulfonamides, trazodone, tricyclic antidepressants, and trimethoprim. Small changes in formulation (i.e., changes in brand) also may increase phenytoin levels or increase the risk of phenytoin toxicity.
- Drugs that may decrease phenytoin levels include bleomycin, carbamazepine, cisplatin, disulfiram, folic acid, intravenous fluids containing glucose, nitrofurantoin, oxacillin, rifampin, salicylates, and vinblastine.
- Primidone decreases the effectiveness of carbamazepine, ethosuximide, felbamate, lamotrigine, oral anticoagulants, oxcarbazepine, topiramate, and valproate.
- Primidone may affect other body chemistries as seen by a decrease in calcium levels and increase in alkaline phosphatase levels.
- Drugs that may increase valproic acid levels or increase risk of toxicity include dicumarol, phenylbutazone, and high doses of salicylate.
- Drugs that may decrease valproic acid levels include carbamazepine, phenobarbital, phenytoin, and primidone.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with monitoring for subtherapeutic, therapeutic, or toxic drug levels.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ These medications are metabolized and excreted by the kidneys and liver. Obtain a history of the patient's genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

- ▶ Lack of consideration for the proper collection time relative to the dosing schedule can provide misleading information that may result in erroneous interpretation of levels, creating the potential for a medication-error-related injury to the patient.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to the dosing schedule. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Antiepileptic drugs antagonize folic acid, and there is a corresponding slight increase in the incidence of fetal malformations in children of epileptic mothers. Women of childbearing age who are taking carbamazepine, phenobarbital, phenytoin, primadone, and/or valproic acid should also be prescribed supplemental folic acid to reduce the incidence of neural tube defects. Neonates born to epileptic mothers taking antiseizure medications during pregnancy may experience a temporary drug-induced deficiency of vitamin K–dependent coagulation factors. This can be avoided by administration of vitamin K to the mother in the last few weeks of pregnancy and to the infant at birth.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding drug interactions. Instruct the patient to

immediately report any unusual sensations (e.g., ataxia, dizziness, dyspnea, lethargy, rash, tremors, mental changes, weakness, or visual disturbances) to his or her HCP. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor

progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, albumin, AST, bilirubin, BUN, creatinine, electrolytes, GGT, and protein blood total and fractions.
- ▶ See the Genitourinary and Hepatobiliary systems tables at the end of the book for related tests by body system.

Antideoxyribonuclease-B, Streptococcal

SYNONYM/ACRONYM: ADNase-B, AntiDNase-B titer, antistreptococcal DNase-B titer, streptodornase.

COMMON USE: To assist in assessing the cause of recent infection, such as streptococcal exposure, by identification of antibodies.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Nephelometry)

Age	Normal Results
1–6 yr	Less than 250 units
7–17 yr	Less than 375 units
18 yr and older	Less than 300 units

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in
Presence of antibodies, especially a rise in titer, is indicative of exposure.

- Post streptococcal glomerulonephritis
- Rheumatic fever
- Streptococcal infections (systemic)

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Antidepressant Drugs (Cyclic): Amitriptyline, Nortriptyline, Protriptyline, Doxepin, Imipramine

SYNONYM/ACRONYM: *Cyclic antidepressants: amitriptyline* (Elavil, Endep, Etrafon, Limbitrol, Triavil); *nortriptyline* (Allegron, Aventyl HCL, Nortrilen, Norval, Pamelor); *protriptyline* (Aventyl, Sinequan, Surmontil, Tofranil, Vivactil); *doxepin* (Adapin, Co-Dax, Novoxapin, Sinequan, Triadapin); *imipramine* (Berkomine, Dimipressin, Iprogen, Janimine, Pentofrane, Presamine, SK-Pramine, Tofranil PM).

COMMON USE: To monitor subtherapeutic, therapeutic, or toxic drug levels in evaluation of effective treatment modalities.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

Drug	Route of Administration	Recommended Collection Time
Amitriptyline	Oral	Trough: immediately before next dose (at steady state)
Nortriptyline	Oral	Trough: immediately before next dose (at steady state)
Protriptyline	Oral	Trough: immediately before next dose (at steady state)
Doxepin	Oral	Trough: immediately before next dose (at steady state)
Imipramine	Oral	Trough: immediately before next dose (at steady state)

NORMAL FINDINGS: (Method: Chromatography for amitriptyline, nortriptyline, protriptyline, and doxepin; immunoassay for imipramine)

Drug	Therapeutic Range Conventional Units	Conversion to SI units	Therapeutic Range SI Units	Half-Life (h)	Volume of Distribution (L/kg)	Protein Binding (%)	Excretion
Amitriptyline	125–250 ng/mL	SI units = Conventional Units x 3.6	450–900 nmol/L	20–40	10–36	85–95	Hepatic
Nortriptyline	50–150 ng/mL	SI units = Conventional Units x 3.8	190–570 nmol/L	20–60	15–23	90–95	Hepatic
Protriptyline	70–250 ng/mL	SI units = Conventional Units x 3.8	266–950 nmol/L	60–90	15–31	91–93	Hepatic
Doxepin	110–250 ng/mL	SI units = Conventional Units x 3.58	394–895 nmol/L	10–25	10–30	75–85	Hepatic
Imipramine	180–240 ng/mL	SI units = Conventional Units x 3.57	643–857 nmol/L	6–18	9–23	60–95	Hepatic

DESCRIPTION: Cyclic antidepressants are used in the treatment of major depression. They have also been used effectively to treat bipolar disorder, panic disorder, attention deficit-hyperactivity disorder (ADHD), obsessive-compulsive disorder (OCD), enuresis, eating disorders (bulimia nervosa in particular), nicotine dependence (tobacco), and cocaine dependence. Numerous drug interactions occur with the cyclic antidepressants.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient ethnicity, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and the ingestion of substances (e.g., foods, herbs, vitamins, and minerals) that can either potentiate or inhibit the intended target concentration. Trough collection times should be documented carefully in relation to the time of medication administration.

The metabolism of many commonly prescribed medications is driven by the cytochrome P450 (CYP450) family of enzymes. Genetic variants can alter enzymatic activity that results in a spectrum of effects ranging from the total absence of drug metabolism to ultrafast metabolism. Impaired drug metabolism can prevent the intended therapeutic effect or even lead to serious adverse drug reactions. Poor metabolizers (PM) are at increased risk for drug-induced side effects due to accumulation of drug in the blood, while ultra-rapid metabolizers (UM) require a higher than normal dosage because the drug is metabolized over a shorter duration than intended. Other genetic

phenotypes used to report CYP450 results are intermediate metabolizer (IM) and extensive metabolizer (EM). Genetic testing can be performed on blood samples submitted to a laboratory. The test method commonly used is polymerase chain reaction. Counseling and informed written consent are generally required for genetic testing. CYP2D6 is a gene in the CYP450 family that metabolizes drugs such as tricyclic antidepressants like nortriptyline, antipsychotics like haloperidol, and beta blockers. Testing for the most common genetic variants of CYP2D6 is used to predict altered enzyme activity and anticipate the most effective therapeutic plan. Incidence of the PM phenotype is estimated to be 10% of Caucasians and Hispanics, 2% of African Americans, and 1% of Asians.

IMPORTANT NOTE

These medications are metabolized and excreted by the liver and are therefore contraindicated in patients with hepatic disease. Information regarding medications must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in calculation of future doses. If administration of the drug is delayed, notify the appropriate department(s) to reschedule the blood draw and notify the requesting health-care provider (HCP) if the delay has caused any real or perceived therapeutic harm.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis and prevention of toxicity
- Evaluate overdose, especially in combination with ethanol (*Note:* Doxepin abuse is unusual.)
- Monitor compliance with therapeutic regimen

POTENTIAL DIAGNOSIS

Level	Response
Normal levels	Therapeutic effect
Subtherapeutic levels	Adjust dose as indicated
Toxic levels	Adjust dose as indicated
Amitriptyline	Hepatic impairment
Nortriptyline	Hepatic impairment
Protriptyline	Hepatic impairment
Doxepin	Hepatic impairment
Imipramine	Hepatic impairment

CRITICAL FINDINGS 

It is important to note the adverse effects of toxic and subtherapeutic levels of antidepressants. Care must be taken to investigate signs and symptoms of too little and too much medication. Note and immediately report to the HCP any critically increased or subtherapeutic values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report.

Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Cyclic Antidepressants

- Amitriptyline: Greater Than 500 ng/mL (SI: Greater Than 1800 nmol/L)
- Nortriptyline: Greater Than 500 ng/mL (SI: Greater Than 1900 nmol/L)
- Protriptyline: Greater Than 500 ng/mL (SI: Greater Than 1900 nmol/L)
- Doxepin: Greater Than 500 ng/mL (SI: Greater Than 1790 nmol/L)
- Imipramine: Greater Than 500 ng/mL (SI: Greater Than 1785 nmol/L)

Signs and symptoms of cyclic antidepressant toxicity include agitation, drowsiness, hallucinations, confusion, seizures, arrhythmias, hyperthermia, flushing, dilation of the pupils, and possible coma. Possible interventions include administration of activated charcoal; emesis; gastric lavage with saline; administration of physostigmine to counteract seizures, hypertension, or respiratory depression; administration of bicarbonate, propranolol, lidocaine, or phenytoin to counteract arrhythmias; and electrocardiographic monitoring.

INTERFERING FACTORS

- Blood drawn in serum separator tubes (gel tubes).
- Cyclic antidepressants may potentiate the effects of oral anticoagulants.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- **Patient Teaching:** Inform the patient this test can assist in monitoring

subtherapeutic, therapeutic, or toxic drug levels.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ These medications are metabolized and excreted by the kidneys and liver. Obtain a history of the patient's genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

- Lack of consideration for the proper collection time relative to the dosing schedule can provide misleading information that may result in erroneous interpretation of levels, creating the potential for a medication-error-related injury to the patient.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
 - ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to the dosing schedule. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the

person collecting the specimen, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Include avoidance of alcohol consumption.
- ▶ Recognize anxiety related to test results and reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding drug interactions. Instruct the patient to immediately report any unusual sensations (e.g., severe headache, vomiting, sweating, visual disturbances) to his or her HCP. Blood pressure should be monitored regularly. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, albumin, AST, bilirubin, BUN, creatinine, CBC, electrolytes, GGT, and protein blood total and fractions.
- ▶ See the Genitourinary and Hepatobiliary systems tables at the end of the book for related tests by body system.

Antidiuretic Hormone

SYNONYM/ACRONYM: Vasopressin, arginine vasopressin hormone, ADH.

COMMON USE: To evaluate disorders that affect urine concentration related to fluctuations of ADH secretion, such as diabetes insipidus.

SPECIMEN: Plasma (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Radioimmunoassay)

Age	Antidiuretic Hormone*	SI Units (Conventional Units × 0.923)
Neonates	Less than 1.5 pg/mL	Less than 1.4 pmol/L
1 day–18 yr (normally hydrated)	0.5–1.7 pg/mL	Less than 0.5–1.6 pmol/L
Adult (normally hydrated)	0–5 pg/mL	0–4.6 pmol/L

*Conventional units.

Recommendation

This test should be ordered and interpreted with results of a serum osmolality.

Serum Osmolality*	Antidiuretic Hormone	SI Units (Conventional Units × 0.923)
270–280 mOsm/kg	Less than 1.5 pg/mL	Less than 1.4 pmol/L
280–285 mOsm/kg	Less than 2.5 pg/mL	Less than 2.3 pmol/L
285–290 mOsm/kg	1–5 pg/mL	0.9–4.6 pmol/L
290–295 mOsm/kg	2–7 pg/mL	1.8–6.5 pmol/L
295–300 mOsm/kg	4–12 pg/mL	3.7–11.1 pmol/L

*Conventional units.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Acute intermittent porphyria (*speculated to be related to the release of ADH from damaged cells in the hypothalamus and effect of hypovolemia; the mechanisms are unclear*)
- Brain tumor (*related to ADH production from the tumor or*

release from damaged cells in an adjacent affected area)

- Disorders involving the central nervous system, thyroid gland, and adrenal gland (*numerous conditions influence the release of ADH*)
- Ectopic production (*related to ADH production from a systemic neoplasm*)
- Guillain-Barré; syndrome (*relationship to syndrome of inappropriate ADH [SIADH] is unclear*)
- Hypovolemia (*potent instigator of ADH release*)

- Nephrogenic diabetes insipidus (*related to lack of renal system response to ADH stimulation; evidenced by increased secretion of ADH*)
- Pain, stress, or exercise (*all are potent instigators of ADH release*)
- Pneumonia (*related to SIADH*)
- Pulmonary tuberculosis (*related to SIADH*)
- SIADH (*numerous conditions influence the release of ADH*)
- Tuberculous meningitis (*related to SIADH*)
- Nephrotic syndrome (*related to destruction of pituitary cells that secrete ADH*)
- Pituitary (central) diabetes insipidus (*related to destruction of pituitary cells that secrete ADH*)
- Pituitary surgery (*related to destruction or removal of pituitary cells that secrete ADH*)
- Psychogenic polydipsia (*evidenced by decreased osmolality, which inhibits secretion of ADH*)

Decreased in

Decreased production or secretion of ADH in response to changes in blood volume or pressure

- Hypervolemia (*related to increased blood volume, which inhibits secretion of ADH*)

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

CRITICAL FINDINGS

Effective treatment of SIADH depends on identifying and resolving the cause of increased ADH production. Signs and symptoms of SIADH are the same as those for hyponatremia, including irritability, tremors, muscle spasms, convulsions, and neurologic changes. The patient has enough sodium, but it is diluted in excess retained water.

Antimicrobial Drugs—Aminoglycosides: Amikacin, Gentamicin, Tobramycin; Tricyclic Glycopeptide: Vancomycin

SYNONYM/ACRONYM: *Amikacin* (Amikin); *gentamicin* (Garamycin, Genoptic, Gentacidin, Gentafair, Gentak, Gentamar, Gentrasul, G-mycin, Oco-Mycin, Spectro-Genta); *tobramycin* (Nebcin, Tobrex); *vancomycin* (Lymphocin, Vancocin, Vancoled).

COMMON USE: To evaluate specific drugs for subtherapeutic, therapeutic, or toxic levels in treatment of infection.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

Drug	Route of Administration	Recommended Collection Time*
Amikacin	IV, IM	Trough: immediately before next dose Peak: 30 min after the end of a 30-min IV infusion
Gentamicin	IV, IM	Trough: immediately before next dose Peak: 30 min after the end of a 30-min IV infusion
Tobramycin	IV, IM	Trough: immediately before next dose Peak: 30 min after the end of a 30-min IV infusion
Tricyclic glycopeptide and vancomycin	IV, PO	Trough: immediately before next dose Peak: 30–60 min after the end of a 60-min IV infusion

*Usually after fifth dose if given every 8 hr or third dose if given every 12 hr. IM = intramuscular; IV = intravenous; PO = by mouth.

NORMAL FINDINGS: (Method: Immunoassay)

Drug	Therapeutic Range Conventional Units	Conversion to SI units	SI Units	Half-Life (hr)	Distribution (L/kg)	Volume of Binding (%)	Excretion
Amikacin Peak	15–30 mcg/mL	SI units = Conventional Units x 1.71	26–51 micromol/L	4–8	0.4–1.3	50	1° renal
	4–8 mcg/mL	SI units = Conventional Units x 1.71	7–14 micromol/L				1° renal
Gentamicin (Standard dosing) Peak	5–10 mcg/mL	SI units = Conventional Units x 2.09	10–21 micromol/L	4–8	0.4–1.3	50	1° renal
	Less than 2 mcg/mL	SI units = Conventional Units x 2.09	Less than 4 micromol/L				1° renal
Tobramycin (Standard dosing) Peak	4–8 mcg/mL	SI units = Conventional Units x 2.09	8.4–16.7 micromol/L	4–8	0.4–1.3	50	1° renal
	Less than 1 mcg/mL	SI units = Conventional Units x 2.09	Less than 2.1 micromol/L				1° renal

Drug	Therapeutic Range Conventional Units	Conversion to SI units	SI Units	Half-Life (hr)	Distribution (L/kg)	Volume of Binding (%)	Excretion
Tobramycin (Once daily dosing)							
Peak	8–12 mcg/mL	SI units = Conventional Units x 2.09	16.7–25.1 micromol/L	4–8	0.4–1.3	50	1° renal
Trough	Less than 0.5 mcg/mL	SI units = Conventional Units x 2.09	Less than 1 micromol/L				1° renal
Vancomycin							
Trough (General) Values vary with indication	5–15 mcg/mL	SI units = Conventional Units x 0.69	3.4–10.4 micromol/L	6–12	0.4–1	10–15	1° renal

DESCRIPTION: The aminoglycoside antibiotics amikacin, gentamicin, and tobramycin are used against many gram-negative (*Acinetobacter*, *Citrobacter*, *Enterobacter*, *Escherichia coli*, *Klebsiella*, *Proteus*, *Providencia*, *Pseudomonas*, *Raoultella*, *Salmonella*, *Serratia*, *Shigella*, and *Stenotrophomonas*) and some gram-positive (*Staphylococcus aureus*) pathogenic microorganisms. Aminoglycosides are poorly absorbed through the gastrointestinal tract and are most frequently administered IV.

Vancomycin is a tricyclic glycopeptide antibiotic used against many gram-positive microorganisms, such as staphylococci, *Streptococcus pneumoniae*, group A β -hemolytic streptococci, enterococci, *Corynebacterium*, and *Clostridium*. Vancomycin has also been used in an oral form for the treatment of pseudomembranous colitis resulting from *Clostridium difficile* infection. This approach is less frequently used because of the emergence of vancomycin-resistant enterococci (VRE).

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and ingestion of substances (e.g., foods, herbals, vitamins, and minerals) that can either potentiate or inhibit the intended target concentration. The most serious side effects of the aminoglycosides and vancomycin are nephrotoxicity and irreversible ototoxicity (uncommon). Peak and

trough collection times should be documented carefully in relation to the time of medication administration. Creatinine levels should be monitored every 2 to 3 days to detect renal impairment due to toxic drug levels.

IMPORTANT NOTE: These medications are metabolized and excreted by the kidneys and are therefore contraindicated in patients with renal disease and cautiously advised in patients with renal impairment. Information regarding medications must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in the calculation of future doses. Some pharmacies use a computerized pharmacokinetics approach to dosing that eliminates the need to be concerned about peak and trough collections; random specimens are adequate. If administration of the drug is delayed, notify the appropriate department(s) to reschedule the blood draw and notify the requesting health-care provider (HCP) if the delay has caused any real or perceived therapeutic harm.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis and prevention of toxicity
- Monitor renal dialysis patients or patients with rapidly changing renal function
- Monitor therapeutic regimen

POTENTIAL DIAGNOSIS

Level	Response
Normal levels	Therapeutic effect
Subtherapeutic levels	Adjust dose as indicated
Toxic levels	Adjust dose as indicated
Amikacin	Renal, hearing impairment
Gentamicin	Renal, hearing impairment
Tobramycin	Renal, hearing impairment
Vancomycin	Renal, hearing impairment

CRITICAL FINDINGS 

The adverse effects of subtherapeutic levels are important. Care should be taken to investigate signs and symptoms of too little and too much medication. Note and immediately report to the health-care provider (HCP) any critically increased or subtherapeutic values and related symptoms.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person

giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Signs and symptoms of toxic levels of these antibiotics are similar and include loss of hearing and decreased renal function. Suspected hearing loss can be evaluated by audiometry testing. Impaired renal function may be identified by monitoring BUN and creatinine levels as well as intake and output. The most important intervention is accurate therapeutic drug monitoring so the medication can be discontinued before irreversible damage is done.

Drug Name	Toxic Levels	
	Conventional Units	Toxic Levels SI Units
Amikacin	Greater than 10 mcg/mL	Greater than 17.1 micromol/L
Gentamicin	Peak greater than 12 mcg/mL, trough greater than 2 mcg/mL	Peak greater than 25.1 micromol/L, trough greater than 4.2 micromol/L
Tobramycin	Peak greater than 12 mcg/mL, trough greater than 2 mcg/mL	Peak greater than 25.1 micromol/L, trough greater than 4.2 micromol/L
Vancomycin	Trough greater than 30 mcg/mL	Trough greater than 20.7 micromol/L

INTERFERING FACTORS

- Blood drawn in serum separator tubes (gel tubes).
- Drugs that may decrease aminoglycoside efficacy include penicillins (e.g., carbenicillin, piperacillin).
- Obtain a culture before and after the first dose of aminoglycosides.
- The risks of ototoxicity and nephrotoxicity are increased by the concomitant administration of aminoglycosides.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in monitoring for subtherapeutic, therapeutic, or toxic drug levels used in treatment of infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Nephrotoxicity is a risk associated with administration of aminoglycosides. Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ototoxicity is a risk associated with administration of aminoglycosides. Obtain a history of the patient's known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and other tests and procedures to assess and diagnose auditory deficit.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.

- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ Obtain a culture, if ordered, before the first dose of aminoglycosides.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to the dosing schedule. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient receiving aminoglycosides to immediately report any unusual symptoms (e.g., hearing loss, decreased urinary output) to his or her HCP.

- ▶ **Nutritional Considerations:** Include avoidance of alcohol consumption.
 - ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
 - ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding food and drug interactions. Answer any questions or address any concerns voiced by the patient or family.
 - ▶ Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include albumin, audiometry hearing loss, BUN, CBC WBC and differential, creatinine, creatinine clearance, cultures bacterial (ear, eye, skin, wound, blood, stool, sputum, urine), otoscopy, potassium, spondee speech recognition test, tuning fork tests, and UA.
- ▶ See the Auditory, Genitourinary, and Immune systems tables at the end of the book for related tests by body system.

Antipsychotic Drugs and Antimanic Drugs: Haloperidol, Lithium

SYNONYM/ACRONYM: *Antipsychotic drugs: haloperidol* (Dozic, Fortunan, Haldol, Haldol Decanoate, Haloneural, Serenace); *antimanic drugs: lithium* (Cibalith-S, Eskalith, Lithane, Lithobid, Lithonate, Lithotabs, PFI-Lith, Phasal).

COMMON USE: To assist in monitoring subtherapeutic, therapeutic, or toxic drug levels related to medical interventions.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

Drug	Route of Administration	Recommended Collection Time
Haloperidol	Oral	Peak: 3–6 hr
Lithium	Oral	Trough: at least 12 hr after last dose; steady state occurs at 90–120 hr

NORMAL FINDINGS: (Method: Chromatography for haloperidol; ion-selective electrode for lithium)

Drug	Therapeutic Range Conventional Units	Conversion to SI Units	Therapeutic Range SI Units	Half-Life (hr)	Volume of Distribution (L/kg)	Protein Binding (%)	Excretion
Haloperidol	6–24 ng/mL	SI units = Conventional Units x 2.66	16–64 nmol/L	15–40	18–30	90	Hepatic
Lithium (chronic)	0.6–1.2 mEq/L	SI units = Conventional Units x 1	0.6–1.2 mmol/L	18–24	0.7–1	0	Renal

DESCRIPTION: Haloperidol is an antipsychotic tranquilizer used for treatment of acute and chronic psychotic disorders, Tourette's syndrome, and hyperactive children with severe behavioral problems. Frequent monitoring is important due to the unstable relationship between dosage and circulating steady-state concentration. Lithium is used in the treatment of manic depression. Daily monitoring of lithium levels is important until the proper dosage is achieved. Lithium is cleared and reabsorbed by the kidney. Clearance is increased when sodium levels are increased and decreased in conditions associated with low sodium levels; therefore, patients receiving lithium therapy should try to maintain a balanced daily intake of sodium. Lithium levels affect other organ systems. A high incidence of pulmonary complications is associated with lithium toxicity. Lithium can also affect cardiac conduction, producing T-wave depressions. These electrocardiographic (ECG) changes are usually insignificant and reversible and are seen in 10% to 20% of patients on lithium therapy. Chronic lithium therapy has been shown to result in enlargement of the thyroid gland in a small percentage of patients. Other medications indicated for use as mood stabilizers include carbamazepine, lamotrigine, and valproic acid. Detailed information is found in the monograph titled "Anticonvulsant Drugs."

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age, patient weight, interacting medications, electrolyte balance, protein levels, water balance, conditions that affect absorption and excretion, and the ingestion of substances (e.g., foods,

herbals, vitamins, and minerals) that can either potentiate or inhibit the intended target concentration. Peak collection times should be documented carefully in relation to the time of medication administration.

The metabolism of many commonly prescribed medications is driven by the cytochrome P450 (CYP450) family of enzymes. Genetic variants can alter enzymatic activity that results in a spectrum of effects ranging from the total absence of drug metabolism to ultrafast metabolism. Impaired drug metabolism can prevent the intended therapeutic effect or even lead to serious adverse drug reactions. Poor metabolizers (PM) are at increased risk for drug-induced side effects due to accumulation of drug in the blood, while ultra-rapid metabolizers (UM) require a higher than normal dosage because the drug is metabolized over a shorter duration than intended. Other genetic phenotypes used to report CYP450 results are intermediate metabolizer (IM) and extensive metabolizer (EM). Genetic testing can be performed on blood samples submitted to a laboratory. The test method commonly used is polymerase chain reaction. Counseling and informed written consent are generally required for genetic testing. CYP2D6 is a gene in the CYP450 family that metabolizes drugs such as antipsychotics like haloperidol, tricyclic antidepressants like nortriptyline, and beta blockers. Testing for the most common genetic variants of CYP2D6 is used to predict altered enzyme activity and anticipate the most effective therapeutic plan. Incidence of the PM Phenotype is estimated to be 10% of Caucasians and Hispanics, 2% of African Americans, and 1% of Asians.

IMPORTANT NOTE

These medications are metabolized and excreted by the liver and kidneys and are therefore contraindicated in patients with hepatic or renal disease. Caution is advised for patients with renal impairment. Information regarding medications must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in calculation of future doses. If administration of the drug is delayed, notify the appropriate department(s) to reschedule the blood draw and notify the requesting health-care (HCP) if the delay has caused any real or perceived therapeutic harm.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis and prevention of toxicity
- Monitor compliance with therapeutic regimen

POTENTIAL DIAGNOSIS

Level	Response
Normal levels	Therapeutic effect
Subtherapeutic levels	Adjust dose as indicated
Toxic levels	Adjust dose as indicated
Haloperidol	Hepatic impairment
Lithium	Renal impairment

CRITICAL FINDINGS 

It is important to note the adverse effects of toxic and subtherapeutic levels. Care must be taken to investigate signs and symptoms of not enough medication and too much medication. Note and immediately report to the HCP

any critically increased or subtherapeutic values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Haloperidol: Greater Than 42 ng/mL (SI: Greater Than 112 nmol/L)

Signs and symptoms of haloperidol toxicity include hypotension, myocardial depression, respiratory depression, and extrapyramidal neuromuscular reactions. Possible interventions include emesis (contraindicated in the absence of gag reflex or central nervous system depression or excitation) and gastric lavage followed by administration of activated charcoal.

Lithium: Greater Than 2 mEq/L (SI: Greater Than 2 mmol/L)

Signs and symptoms of lithium toxicity include ataxia, coarse tremors, muscle rigidity, vomiting, diarrhea, confusion, convulsions, stupor, T-wave flattening, loss of consciousness, and possible coma. Possible interventions include administration of activated charcoal, gastric lavage, and administration of intravenous fluids with diuresis.

INTERFERING FACTORS

- Blood drawn in serum separator tubes (gel tubes).
- Haloperidol may increase levels of tricyclic antidepressants and increase the risk of lithium toxicity.
- Drugs that may increase lithium levels include angiotensin-converting enzyme inhibitors, some NSAIDs, and thiazide diuretics.
- Drugs and substances that may decrease lithium levels include acetazolamide, osmotic diuretics, theophylline, and caffeine.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in monitoring subtherapeutic, therapeutic, or toxic drug levels.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ These medications are metabolized and excreted by the kidneys and liver. Obtain a history of the patient's genitourinary and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

- ▶ Lack of consideration for the proper collection time relative to the dosing schedule can provide misleading information that may result in erroneous interpretation of levels, creating the potential for a medication-error-related injury to the patient.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Consider recommended collection time in relation to the dosing schedule. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Include avoidance of alcohol consumption.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and instructions regarding drug interactions.

- ▶ Instruct the patient receiving haloperidol to immediately report any unusual symptoms (e.g., arrhythmias, blurred vision, dry eyes, repetitive uncontrolled movements) to his or her HCP. Instruct the patient receiving lithium to immediately report any unusual symptoms (e.g., anorexia, nausea, vomiting, diarrhea, dizziness, drowsiness, dysarthria, tremor, muscle twitching, visual disturbances) to his or her HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related laboratory tests include albumin, BUN, calcium, creatinine, ECG, glucose, magnesium, osmolality urine, potassium, sodium, T₄, and TSH.
- ▶ See the Genitourinary and Hepatobiliary systems tables at the end of the book for related tests by body system.

Antithrombin III

SYNONYM/ACRONYM: Heparin cofactor assay, ATIII.

COMMON USE: To assist in diagnosing heparin resistance or disorders resulting from a hypercoagulable state such as thrombus.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Chromogenic Immunoturbidimetric)

Age	Conventional Units (% of Normal)
1–4 days	39–87%
5–29 days	41–93%
1–3 mo	48–108%
3–6 mo	73–121%
6–12 mo	84–124%
1–5 yr	82–139%
6–17 yr	90–131%
18 yr-older adult	80–120%

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS*Increased in*

- Acute hepatitis
- Renal transplantation (*Some studies have demonstrated high levels of AT III in proximal tubule epithelial cells at the time of renal transplant. The exact relationship between the kidneys and*

AT III levels is unknown. It is believed the kidneys may play a role in maintaining plasma levels of AT III as evidenced by the correlation between renal disease and low AT III levels.)

- Vitamin K deficiency (*decreased consumption related to impaired coagulation factor function*)

Decreased in

- Carcinoma (*related to decreased synthesis*)
- Chronic liver failure (*related to decreased synthesis*)
- Cirrhosis (*related to decreased synthesis*)

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

- Congenital deficiency
- Disseminated intravascular coagulation (*related to increased consumption*)
- Liver transplantation or partial hepatectomy (*related to decreased synthesis*)
- Nephrotic syndrome (*related to increased protein loss*)
- Pulmonary embolism (*related to increased consumption*)
- Septic shock (*related to increased consumption and decreased synthesis due to hepatic impairment*)
- Venous thrombosis (*related to increased consumption*)

CRITICAL FINDINGS: N/A

α_1 -Antitrypsin and α_1 -Antitrypsin Phenotyping

SYNONYM/ACRONYM: α_1 -antitrypsin: A₁AT, α_1 -AT, AAT; α_1 -antitrypsin phenotyping: A₁AT phenotype, α_1 -AT phenotype, AAT phenotype, Pi phenotype.

COMMON USE: To assist in the identification of chronic obstructive pulmonary disease (COPD) and liver disease associated with α_1 -antitrypsin (α_1 -AT) deficiency.

SPECIMEN: Serum (1 mL) for α_1 -AT and serum (2 mL) for α_1 -AT phenotyping collected in a gold-, red-, or red/gray-top tube. Whole blood from one full lavender-top (EDTA) is also acceptable.

NORMAL FINDINGS: (Method: Rate nephelometry for α_1 -AT, isoelectric focusing/high-resolution electrophoresis for α_1 -AT phenotyping)

α_1 -Antitrypsin

Age	Conventional Units	SI Units (Conventional Units × 0.01)
0–1 mo	124–348 mg/dL	1.24–3.48 g/L
2–6 mo	111–297 mg/dL	1.11–2.97 g/L
7 mo–2 yr	95–251 mg/dL	0.95–2.51 g/L
3–19 yr	110–279 mg/dL	1.1–2.79 g/L
Adult	126–226 mg/dL	1.26–2.26 g/L

α_1 -Antitrypsin Phenotyping

There are three major protease inhibitor phenotypes:

- MM—Normal
- SS—Intermediate; heterozygous
- ZZ—Markedly abnormal; homozygous

The total level of measurable α_1 -AT varies with genotype. The effects of α_1 -AT deficiency depend on the patient's personal habits but are most severe in patients who smoke tobacco.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS**Increased in**

- Acute and chronic inflammatory conditions (*related to rapid, nonspecific response to inflammation*)
- Carcinomas (*related to rapid, nonspecific response to inflammation*)
- Estrogen therapy

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

- Postoperative recovery (*related to rapid, nonspecific response to inflammation or stress*)
- Pregnancy (*related to rapid, nonspecific response to stress*)
- Steroid therapy
- Stress (extreme physical) (*related to rapid, nonspecific response to stress*)

Decreased in

- COPD (*related to malnutrition and evidenced by decreased protein synthesis*)
- Homozygous α_1 -AT-deficient patients (*related to decreased protein synthesis*)
- Liver disease (severe) (*related to decreased protein synthesis*)
- Liver cirrhosis (infant or child) (*related to decreased protein synthesis*)
- Malnutrition (*related to insufficient protein intake*)
- Nephrotic syndrome (*related to increased protein loss from diminished renal function*)

CRITICAL FINDINGS: N/A

Apolipoproteins: A, B, and E

SYNONYM/ACRONYM: Apo A (Apo A1), Apo B (Apo B100), and Apo E.

COMMON USE: To identify levels of circulating lipoprotein to evaluate the risk of coronary artery disease.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube or plasma collected in a green- (heparin) or lavender-top (EDTA) tube for Apo A and Apo B; Plasma (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Immunonephelometry for Apo A and Apo B; PCR with restriction length enzyme digestion and polyacrylamide gel electrophoresis for Apo E)

Apolipoprotein A

Age	Conventional Units	SI Units (Conventional Units × 0.01)
Newborn		
Male	41–93 mg/dL	0.41–0.93 g/L
Female	38–106 mg/dL	0.38–1.06 g/L
6 mo–4 yr		
Male	67–163 mg/dL	0.67–1.63 g/L
Female	60–148 mg/dL	0.6–1.48 g/L
Adult		
Male	81–166 mg/dL	0.81–1.66 g/L
Female	80–214 mg/dL	0.80–2.14 g/L

Apolipoprotein B

Age	Conventional Units	SI Units (Conventional Units × 0.01)
Newborn–5 yr	11–31 mg/dL	0.11–0.31 g/L
5–17 yr		
Male	47–139 mg/dL	0.47–1.39 g/L
Female	41–96 mg/dL	0.41–0.96 g/L
Adult		
Male	46–174 mg/dL	0.46–1.74 g/L
Female	46–142 mg/dL	0.46–1.42 g/L

Normal Apo E: Homozygous phenotype for ϵ_3/ϵ_3 .

DESCRIPTION: Apolipoproteins assist in the regulation of lipid metabolism by activating and inhibiting enzymes required for this process. The apolipoproteins also help keep lipids in solution as they circulate in the blood and direct the lipids toward the correct target organs and tissues in the body. A number of types of apolipoproteins have been identified (A, B, C, D, E, H, J), each of which contain subgroups. Apolipoprotein A (Apo A), the major component of high-density lipoprotein (HDL), is synthesized in the liver and intestines. Apo A-I activates the enzyme lecithin-cholesterol acyltransferase (LCAT), whereas Apo A-II inhibits LCAT. It is believed

that Apo A measurements may be more important than HDL cholesterol measurements as a predictor of coronary artery disease (CAD). There is an inverse relationship between Apo A levels and risk for developing CAD. Because of difficulties with method standardization, the above-listed reference ranges should be used as a rough guide in assessing abnormal conditions. Values for African Americans are 5 to 10 mg/dL higher than values for whites. Apolipoprotein B (Apo B), the major component of the low-density lipoproteins (chylomicrons, low-density lipoprotein [LDL], and very-low-density lipoprotein), is synthesized in the liver and intestines.

Apolipoprotein E is found in most lipoproteins, except LDL, and is synthesized in a variety of cell types including liver, brain astrocytes, spleen, lungs, adrenals, ovaries, kidneys, muscle cells, and in macrophages. The largest amount is produced by the liver; the next significant amount is produced by the brain. There are three forms of Apo E: apo-E 2, apo-E 3, and apo-E 4, and six possible combinations; of these, Apo-E 3 (e3/3e) is the fully functioning form. The varied roles of Apo E include removal of chylomicrons and very-low-density lipoprotein (VLDL) from the circulation by binding to LDL. The Apo E2 isoform demonstrates significantly less LDL receptor binding, which results in impaired clearance of chylomicrons, VLDL, and triglyceride remnants. The presence of Apo E isoforms E2 and E4 is associated with high cholesterol levels, high triglyceride levels, and the premature development of atherosclerosis. The presence of the E2 isoform is associated with type III hyperlipidemia, a familial dyslipidemia, which is important to distinguish from other causes of hyperlipidemia to determine the correct treatment regimen. Apo E4 is being used in association with studies of predisposing factors in the development of Alzheimer's disease. Detailed information is found in the study titled "Alzheimer's Disease Markers."

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluation for risk of CAD

POTENTIAL DIAGNOSIS

Apolipoproteins are the protein portion of lipoproteins. Their function is to transport and to assist in cell surface receptor recognition and cellular absorption of lipoproteins to be used as energy. While studies of the exact role of apolipoproteins in health and disease continue, there is a very strong association between Apo A and HDL "good" cholesterol and Apo B and LDL "bad" cholesterol.

Apolipoprotein A

Increased in

- Familial hyper- α -lipoproteinemia
- Pregnancy
- Weight reduction

Decreased in

- Abetalipoproteinemia
- Cholestasis
- Chronic renal failure
- Coronary artery disease
- Diabetes (uncontrolled)
- Diet high in carbohydrates or polyunsaturated fats
- Familial deficiencies of related enzymes and lipoproteins (e.g., Tangier's disease)
- Hemodialysis
- Hepatocellular disorders
- Hypertriglyceridemia
- Nephrotic syndrome
- Premature coronary heart disease
- Smoking

Apolipoprotein B

Increased in

- Anorexia nervosa
- Biliary obstruction
- Coronary artery disease
- Cushing's syndrome
- Diabetes
- Dysglobulinemia
- Emotional stress
- Hemodialysis
- Hepatic disease
- Hepatic obstruction
- Hyperlipoproteinemias

- Hypothyroidism
- Infantile hypercalcemia
- Nephrotic syndrome
- Porphyria
- Pregnancy
- Premature CAD
- Renal failure
- Werner's syndrome

Decreased in

- Acute stress (burns, illness)
- Chronic anemias
- Chronic pulmonary disease
- Familial deficiencies of related enzymes and lipoproteins (e.g., Tangier's disease)
- Hyperthyroidism
- Inflammatory joint disease
- Intestinal malabsorption
- α -Lipoprotein deficiency (Tangier's disease)
- Malnutrition
- Myeloma
- Reye's syndrome
- Weight reduction

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that may increase Apo A levels include anti-convulsants, beclobrate, bezafibrate, ciprofibrate, estrogens, furosemide, lovastatin, pravastatin, prednisolone, simvastatin, and ethanol (abuse).
- Drugs that may decrease Apo A levels include androgens, β -blockers, diuretics, and probucol.
- Drugs that may increase Apo B levels include amiodarone, androgens, β -blockers, catecholamines, cyclosporine, diuretics, ethanol (abuse), etretinate, glucogenic corticosteroids, oral contraceptives, and phenobarbital.
- Drugs that may decrease Apo B levels include beclobrate, captopril, cholestyramine, fibrates, ketanserin, lovastatin, niacin, nifedipine, pravastatin, prazosin, probucol, and simvastatin.

- Drugs that may decrease Apo E levels include bezafibrate, fluvastatin, gemfibrozil, ketanserin, lovastatin, niacin, nifedipine, oral contraceptives, pravastatin, probucol, and simvastatin.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing and monitoring risk for coronary artery (heart) disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medication, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to abstain from food for 6 to 12 hr before specimen collection.
- ▶ Note that there are no fluid or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Ensure that the patient has complied with dietary or activity restrictions, and pretesting preparations; assure that food has been restricted for at least 6 to 12 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet as directed by the HCP.
- ▶ **Nutritional Considerations:** Decreased Apo A and/or increased Apo B levels may be associated with CAD. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely

decrease sodium intake, achieve a normal weight, ensure regular participation of moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the ACC and AHA in conjunction with the NHLBI recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the DASH diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

- Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- ▶ Reinforce information given by the patient's HCP regarding further testing,

treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include Alzheimer's disease markers, antiarrhythmic drugs,

AST, ANP, BNP, blood gases, CRP, calcium and ionized calcium, cholesterol (total, HDL, and LDL), CK and isoenzymes, CT scoring, echocardiography, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, myocardial infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, triglycerides, and troponin.

- ▶ See the Cardiovascular System table at the end of the book for related tests by body system.

Arthrogram

SYNONYM/ACRONYM: Joint study.

COMMON USE: To assess and identify the cause of persistent joint pain and monitor the progression of joint disease.

AREA OF APPLICATION: Shoulder, elbow, wrist, hip, knee, ankle, temporomandibular joint.

CONTRAST: Iodinated or gadolinium contrast; air may also be used with or without liquid contrast.

DESCRIPTION: An arthrogram evaluates the cartilage, ligaments, and bony structures that compose a joint. After local anesthesia is administered to the area of interest, a fluoroscopically guided small-gauge needle is inserted into the joint space. Fluid in the joint space is aspirated and sent to the laboratory for analysis. A water-based or air-contrast medium is injected into the joint space to outline the soft tissue structures and the contour of the joint. After a brief exercise of the joint, radiographs, computed tomography (CT), or magnetic resonance images (MRIs) are obtained.

Arthrography may be performed when there has been persistent, unexplained pain, discomfort, and/or dysfunction of a joint. It is instrumental in evaluating damage from recurrent dislocations of a joint, visualizing synovial cysts, and identifying acute or chronic tears in the soft tissue of the joint. Arthrography can also be used therapeutically to remove fluid in the joint space or to inject medications for pain relief.

Pediatrics Arthrography is usually performed on young athletes with a suspected chronic joint injury or acute joint trauma.

Hip arthrography is performed most often in children to evaluate congenital hip dislocation, hip dysplasia, or Perthes' disease, before and after treatment. Young children may need to be sedated in order to remain still during the procedure. Parents should be encouraged to ask about preparation for sedation prior to the procedure including any ordered medications or restrictions regarding medications, diet, and activity.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus.
-  Conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate

to severe reactions to ionic contrast medium.

-  Patients with infection in the joint of interest.
-  Patients with active arthritis.
-  Patients with bleeding disorders receiving an arthrogram, ***because the injection site may not stop bleeding.***
-  Patients with metal in their body, such as shrapnel or ferrous metal in the eye, and who will be having associated MRI studies.
-  Patients with cardiac pacemakers, and who will be having associated MRI studies ***because the pacemaker can be deactivated by MRI.***
-  Use of gadolinium-based contrast agents (GBCAs) is contraindicated in patients with acute or chronic severe renal insufficiency (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks, and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.
-  Elderly and compromised patients who are chronically dehydrated before the test, ***because of their risk of contrast-induced renal failure.***

INDICATIONS

- Evaluate pain, swelling, or dysfunction of a joint
- Monitor disease progression

POTENTIAL DIAGNOSIS

Normal findings in

- Normal bursae, menisci, ligaments, and articular cartilage of the joint (note: the cartilaginous surfaces

and menisci should be smooth, without evidence of erosion, tears, or disintegration)

Abnormal findings in

- Arthritis
- Cysts
- Diseases of the cartilage (chondromalacia)
- Injury to the ligaments
- Joint derangement
- Meniscal tears or laceration
- Muscle tears
- Osteochondral fractures
- Osteochondritis dissecans
- Synovial tumor
- Synovitis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects within the examination field which may inhibit organ visualization and can produce unclear images
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent

x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the joint being examined.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and previously performed laboratory tests and diagnostic and surgical procedures. Ensure that the results of blood tests are obtained and recorded before the procedure, especially coagulation tests, BUN, and creatinine, if contrast medium is to be used. Obtain a history of renal dysfunction if the use of iodinated contrast medium (CT) or GBCA (MRI) is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.

▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test.

Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).

▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in the radiology department by an HCP and takes approximately 30 to 60 min.

▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as saline, anesthetics, contrast medium, or sedatives.

▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Injection of the contrast is an invasive procedure. Complications are rare but do include risk for allergic reaction (**related to contrast reaction**); cardiac arrhythmias; hematoma (**related to blood leakage into the tissue following needle insertion**); bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**); infection (**which might occur if**

bacteria from the skin surface is introduced at the puncture site); and vascular or nerve injury (**which might occur if the needle strikes a nerve or nearby blood vessel**).

▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

▶ Ensure that the patient has removed all external metallic objects prior to the procedure.

▶ Have emergency equipment readily available.

▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.

▶ Have emergency equipment readily available.

▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

▶ Place the patient on the table in a supine position.

▶ The skin surrounding the joint is aseptically cleaned and anesthetized.

▶ A small-gauge needle is inserted into the joint space.

▶ Any fluid in the space is aspirated and sent to the laboratory for analysis.

▶ Contrast medium is inserted into the joint space with fluoroscopic guidance.

▶ The needle is removed, and the joint is exercised to help distribute the contrast medium.

▶ X-rays or MRIs are taken of the joint.

▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

▶ During x-ray imaging, lead protection is placed over the gonads to prevent their irradiation.

▶ If MRI images are taken, supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe/assess the joint for swelling after the test. Apply ice as needed.
- ▶ Instruct the patient to use a mild analgesic (aspirin, acetaminophen), as ordered, if there is discomfort.
- ▶ Advise the patient to avoid strenuous activity until approved by the HCP.
- ▶ Instruct the patient to notify the HCP if fever, increased pain, drainage, warmth, edema, or swelling of the joint occurs.
- ▶ Inform the patient that noises from the joint after the procedure are common and should disappear 24 to 48 hr after the procedure.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to anticipated chronic pain resulting from joint inflammation, impairment in mobility, musculoskeletal deformity, and loss of independence. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate

the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org) or for the Arthritis Foundation (www.arthritis.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antibodies anticyclic citrullinated peptide, ANA, arthroscopy, BMD, bone scan, BUN, CBC, CRP, creatinine, ESR, MRI musculoskeletal, PT/INR, radiography bone, RF, synovial fluid analysis, and uric acid.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Arthroscopy

SYNONYM/ACRONYM: N/A.**COMMON USE:** To obtain direct visualization of a specific joint to assist in diagnosis of joint disease.**AREA OF APPLICATION:** Joints.**CONTRAST:** None.

DESCRIPTION: Arthroscopy provides direct visualization of a joint through the use of a fiberoptic endoscope. The arthroscope has a light, fiberoptics, and lenses; it

connects to a monitor, and the images are recorded for future study and comparison. This procedure is used for inspection of joint structures, performance of

a biopsy, and surgical repairs to the joint. Meniscus removal, spur removal, and ligamentous repair are some of the surgical procedures that may be performed.

This procedure is contraindicated for

-  Patients with bleeding disorders undergoing arthroscopy, **because the insertion site may not stop bleeding.**
-  Patients with infection in the joint of interest or on the skin surrounding the area of the insertion site **because the infection can be introduced into the joint by the contaminated arthroscope.**
-  Patients with active arthritis.
-  Patients who have had an arthrogram within the last 14 days **related to residual inflammation from the contrast.**

INDICATIONS

- Detect torn ligament or tendon
- Evaluate joint pain and damaged cartilage
- Evaluate meniscal, patellar, condylar, extrasynovial, and synovial injuries or diseases of the knee
- Evaluate the extent of arthritis
- Evaluate the presence of gout
- Monitor effectiveness of therapy
- Remove loose objects

POTENTIAL DIAGNOSIS

Normal findings in

- Normal muscle, ligament, cartilage, synovial, and tendon structures of the joint

Abnormal findings in

- Arthritis
- Chondromalacia
- Cysts
- Degenerative joint changes
- Ganglion or Baker's cyst

- Gout or pseudogout
- Joint tumors
- Loose bodies
- Meniscal disease
- Osteoarthritis
- Osteochondritis
- Rheumatoid arthritis
- Subluxation, fracture, or dislocation
- Synovitis
- Torn cartilage
- Torn ligament
- Torn rotator cuff
- Trapped synovium

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Fibrous ankylosis of the joint preventing effective use of the arthroscope.
- Joints with flexion of less than 50°.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the joint being examined.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex and anesthetics.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain, and explain that some discomfort and pain may be experienced during the test. Inform the patient that the procedure is performed by a health-care provider (HCP), usually in the surgery department, and takes approximately 30 to 60 min.
- ▶ Explain that a preprocedure sedative may be administered to promote relaxation, as ordered.
- ▶ Crutch walking should be taught before the procedure if it is anticipated postoperatively.
- ▶ Hair around the joint area and areas 5 to 6 in. above and below the joint are clipped and prepared for the procedure.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

- Possible complications include infection, phlebitis, hemarthrosis, hematoma, swelling, formation of blood clots, and synovial sac rupture.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with food and fluid restrictions for at least 6 to 8 hr prior to the procedure.
- ▶ Resuscitation equipment and patient monitoring equipment must be available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ The extremity is scrubbed, elevated, and wrapped with an elastic bandage from the distal portion of the extremity to the proximal portion to drain as much blood from the limb as possible.
- ▶ A pneumatic tourniquet placed around the proximal portion of the limb is inflated, and the elastic bandage is removed.
- ▶ As an alternative to a tourniquet, a mixture of lidocaine with epinephrine and sterile normal saline may be instilled into the joint to help reduce bleeding.
- ▶ The joint is placed in a 45° angle, and a local anesthetic is administered.
- ▶ A small incision is made in the skin in the lateral or medial aspect of the joint.
- ▶ The arthroscope is inserted into the joint spaces. The joint is manipulated as it is visualized. Added puncture sites may be needed to provide a full view of the joint.
- ▶ Biopsy or treatment can be performed at this time, and photographs should be taken for future reference.
- ▶ After inspection, specimens may be obtained for cytological and microbiological study. All specimens are placed in appropriate containers, labeled with the corresponding patient demographics, date and time of collection, site location, and promptly sent to the laboratory.

- ▶ The joint is irrigated, and the arthroscope is removed. Manual pressure is applied to the joint to remove remaining irrigation solution.
- ▶ The incision sites are sutured, and a pressure dressing is applied.
- ▶ Sterile gloves and gowns are worn throughout the procedure.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Advise the patient to avoid strenuous activity involving the joint until approved by the HCP. Driving may be restricted for a period of time, as ordered by the HCP.
- ▶ Instruct the patient to resume normal diet and medications, as directed by the HCP. The patient may be given specific activity restrictions and may also need to be taught to use crutches.
- ▶ Monitor the patient's circulation and sensations in the joint area.
- ▶ Instruct the patient to immediately report symptoms such as fever, excessive bleeding, difficulty breathing, incision site redness, swelling, and tenderness.
- ▶ Instruct the patient to elevate the joint when sitting and to avoid overbending of the joint to reduce swelling and formation of blood clots.
- ▶ Instruct the patient to take an analgesic for joint discomfort after the procedure; ice bags may be used to reduce postprocedure swelling.
- ▶ Inform the patient to shower after 48 hr but to avoid a tub bath until after his or her appointment with the HCP.

- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to anticipated chronic pain resulting from joint inflammation, impairment in mobility, musculoskeletal deformity, and loss of independence. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org) or for the Arthritis Foundation (www.arthritis.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include anti-cyclic citrullinated peptide, ANA, arthrogram, BMD, bone scan, CBC, CRP, ESR, MRI musculoskeletal, radiography of the bone, RF, synovial fluid analysis, and uric acid.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Aspartate Aminotransferase

SYNONYM/ACRONYM: Serum glutamic-oxaloacetic transaminase, AST, SGOT.

COMMON USE: Considered an indicator of cellular damage in liver disease, such as hepatitis or cirrhosis; and in heart disease, such as myocardial infarction.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Spectrophotometry, enzymatic at 37°C)

Age	Conventional Units	SI Units (Conventional Units \times 0.017)
Newborn	25–75 units/L	0.43–1.28 micro kat/L
10 days–23 mo	15–60 units/L	0.26–1.02 micro kat/L
2–3 yr	10–56 units/L	0.17–0.95 micro kat/L
4–6 yr	20–39 units/L	0.34–0.66 micro kat/L
7–19 yr	12–32 units/L	0.2–0.54 micro kat/L
20–49 yr		
Male	20–40 units/L	0.34–0.68 micro kat/L
Female	15–30 units/L	0.26–0.51 micro kat/L
Greater than 50 yr (older adult)		
Male	10–35 units/L	0.17–0.6 micro kat/L
Female	10–35 units/L	0.17–0.6 micro kat/L

Values may be slightly elevated in older adults due to the effects of medications and the presence of multiple chronic or acute diseases with or without muted symptoms.

DESCRIPTION: Aspartate aminotransferase (AST) is an enzyme that catalyzes the reversible transfer of an amino group between aspartate and α -ketoglutaric acid in the citric acid or Krebs cycle, a powerful and essential biochemical pathway for releasing stored energy. It was formerly known as serum glutamic-oxaloacetic transaminase (SGOT). AST exists in large amounts in liver and myocardial cells and in smaller but significant amounts in skeletal muscle, kidneys, pancreas, red blood cells, and the brain. Serum AST rises when there is damage to the tissues and cells where the enzyme is found and levels directly reflect the extent of damage. AST values greater than 500 units/L are usually associated with hepatitis and other hepatocellular diseases in an acute phase. AST levels are very elevated at birth, decrease with age to adulthood, and increase slightly in elderly adults.

Note: Measurement of AST in evaluation of myocardial infarction has been replaced by more sensitive tests, such as creatine kinase-MB fraction (CK-MB) and troponin.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of disorders or injuries involving the tissues where AST is normally found
- Assist (formerly) in the diagnosis of myocardial infarction (*Note:* AST rises within 6 to 8 hr, peaks at 24 to 48 hr, and declines to normal within 72 to 96 hr of a myocardial infarction if no further cardiac damage occurs)
- Compare serially with alanine aminotransferase levels to track the course of hepatitis
- Monitor response to therapy with potentially hepatotoxic or nephrotoxic drugs

- Monitor response to treatment for various disorders in which AST may be elevated, with tissue repair indicated by declining levels

POTENTIAL DIAGNOSIS

Increased in

AST is released from any damaged cell in which it is stored, so conditions that affect the liver, kidneys, heart, pancreas, red blood cells, or skeletal muscle, and cause cellular destruction demonstrate elevated AST levels.

Significantly Increased in (greater than five times normal levels)

- Acute hepatitis (*AST is very elevated in acute viral hepatitis*)
- Acute hepatocellular disease (*especially related to chemical toxicity or drug overdose; moderate doses of acetaminophen have initiated severe hepatocellular disease in alcoholics*)
- Acute pancreatitis
- Shock

Moderately Increased in (three to five times normal levels)

- Alcohol abuse (chronic)
- Biliary tract obstruction
- Cardiac arrhythmias
- Cardiac catheterization, angioplasty, or surgery
- Cirrhosis
- Chronic hepatitis
- Congestive heart failure
- Infectious mononucleosis
- Liver tumors
- Muscle diseases (e.g., dermatomyositis, dystrophy, gangrene, polymyositis, trichinosis)
- Myocardial infarct
- Reye's syndrome
- Trauma (*related to injury or surgery of liver, head, and other sites where AST is found*)

Slightly Increased in (two to three times normal)

- Cerebrovascular accident
- Cirrhosis, fatty liver (*related to obesity, diabetes, jejunoileal bypass, administration of total parenteral nutrition*)
- Delirium tremens
- Hemolytic anemia
- Pericarditis
- Pulmonary infarction

Decreased in

- Hemodialysis (*presumed to be related to a corresponding deficiency of vitamin B₆ observed in hemodialysis patients*)
- Uremia (*related to a buildup of toxins which modify the activity of coenzymes required for transaminase activity*)
- Vitamin B₆ deficiency (*related to the lack of vitamin B₆, a required cofactor for the transaminases*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase AST levels by causing cholestasis include amitriptyline, anabolic steroids, androgens, benzodiazepines, chlorothiazide, chlorpropamide, dapsone, erythromycin, estrogens, ethionamide, gold salts, imipramine, mercaptopurine, nitrofurans, oral contraceptives, penicillins, phenothiazines, progesterone, propoxyphene, sulfonamides, tamoxifen, and tolbutamide.
- Drugs that may increase AST levels by causing hepatocellular damage include acetaminophen, acetylsalicylic acid, allopurinol, amiodarone, anabolic steroids, anticonvulsants, asparaginase, azithromycin, bromocriptine, captopril, cephalosporins, chloramphenicol,

clindamycin, clofibrate, danazol, enflurane, ethambutol, ethionamide, fenofibrate, fluconazole, fluoroquinolones, foscarnet, gentamicin, indomethacin, interferon, interleukin-2, levamisole, levodopa, lincomycin, low-molecular-weight heparin, methylodopa, monoamine oxidase inhibitors, naproxen, nifedipine, nitrofurans, oral contraceptives, probenecid, procainamide, quinine, ranitidine, retinol, ritodrine, sulfonyleureas, tetracyclines, tobramycin, and verapamil.

- Drugs that may decrease AST levels include allopurinol, cyclosporine, interferon alpha, naltrexone, progesterone, trifluoperazine, and ursodiol.
- Hemolysis falsely increases AST values.
- Hemodialysis falsely decreases AST values.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing liver function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain, and explain to the patient that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased AST levels may be associated with liver disease. Dietary recommendations may be indicated and will vary depending on the condition and its severity. Currently, there are no specific medications that can be given to cure hepatitis, but elimination of alcohol ingestion and a diet optimized for convalescence are commonly included in the treatment plan. A high-calorie, high-protein, moderate-fat diet with a high fluid intake is often recommended for patients with hepatitis. Treatment of cirrhosis is different; a low-protein diet

may be in order if the patient's liver can no longer process the end products of protein metabolism. A diet of soft foods may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs) rather than complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should be observed carefully for the development of ascites, in which case fluid and electrolyte balance requires strict attention.

▶ **Nutritional Considerations:** Increased AST levels may be associated with coronary artery disease (CAD). Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the ACC and AHA in conjunction with the NHLBI recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and

lean poultry. A similar dietary pattern known as the DASH diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.

- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- ▶ Instruct the patient to immediately report chest pain and changes in breathing pattern to the HCP.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include acetaminophen, ALT, albumin, ALP, ammonia, AMA/ASMA, α_1 -antitrypsin/phenotyping, bilirubin and fractions, biopsy liver,

cholangiography percutaneous transhepatic, cholangiography post-op, CT biliary tract and liver, ERCP, ethanol, ferritin, GGT, hepatitis antigens and antibodies, hepatobiliary scan, iron/total iron-binding capacity, liver and spleen scan, protein and fractions, PT/INR, US abdomen, and US liver if liver disease is suspected; and anti-arrhythmic drugs, apolipoprotein A and B, ANP, BNP, blood gases, CRP, calcium/ionized calcium, CT scoring,

cholesterol (total, HDL, and LDL), CK, echocardiography, Holter monitor, homocysteine, LDH, MRI chest, myocardial infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, triglycerides, and troponin if myocardial infarction is suspected.

▶ See the Cardiovascular and Hepatobiliary systems tables at the end of the book for related tests by body system.

Atrial Natriuretic Peptide

SYNONYM/ACRONYM: Atrial natriuretic hormone, atrial natriuretic factor, ANF, ANH, APN.

COMMON USE: To assist in diagnosing and monitoring congestive heart failure (CHF) and to differentiate CHF from other causes of dyspnea.

SPECIMEN: Plasma (1 mL) collected in a chilled, lavender-top tube. Specimen should be transported tightly capped and in an ice slurry.

NORMAL FINDINGS: (Method: Radioimmunoassay)

Conventional Units	SI Units (Conventional Units × 1)
20–77 pg/mL	20–77 ng/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

ANP is secreted in response to increased hemodynamic load caused by physiological stimuli as with atrial stretch or endocrine stimuli from the aldosterone/renin system.

- Asymptomatic cardiac volume overload
- CHF
- Elevated cardiac filling pressure
- Paroxysmal atrial tachycardia

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Audiometry, Hearing Loss

SYNONYM/ACRONYM: N/A.

COMMON USE: To evaluate hearing loss in school-age children but can be used for all ages.

AREA OF APPLICATION: Ears.

CONTRAST: N/A.

DESCRIPTION: Tests to estimate hearing ability can be performed on patients of any age (e.g., at birth before discharge from a hospital or birthing center, as part of a school screening program, or as adults if indicated). Hearing loss audiometry includes quantitative testing for a hearing deficit. An audiometer is used to measure and record thresholds of hearing by air conduction and bone conduction tests. The test results determine if hearing loss is conductive, sensorineural, or a combination of both. An elevated air-conduction threshold with a normal bone-conduction threshold indicates a conductive hearing loss. An equally elevated threshold for both air and bone conduction indicates a sensorineural hearing loss. An elevated threshold of air conduction that is greater than an elevated threshold of bone conduction indicates a composite of both types of hearing loss. A conductive hearing loss is caused by an abnormality in the external auditory canal or middle ear, and a sensorineural hearing loss by an abnormality in the inner ear or of the VIII (auditory) nerve. Sensorineural hearing loss can be further differentiated clinically by sensory (cochlear) or neural (VIII nerve) lesions. Sensorineural hearing loss is permanent. Additional information

for comparing and differentiating between conductive and sensorineural hearing loss can be obtained from hearing loss tuning fork tests. Every state and territory in the United States has a newborn screening program that includes early hearing loss detection and intervention (EHDI). The goal of EHDI is to assure that permanent hearing loss is identified before 3 mo of age, appropriate and timely intervention services are provided before 6 mo of age, families of infants with hearing loss receive culturally competent support, and tracking and data management systems for newborn hearing screens are linked with other relevant public health information systems.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine the need for a type of hearing aid and evaluate its effectiveness
- Determine the type and extent of hearing loss and if further radiological, audiological, or vestibular procedures are needed to identify the cause
- Evaluate communication disabilities and plan for rehabilitation interventions
- Evaluate degree and extent of pre-operative and postoperative hearing

loss following stapedectomy in patients with otosclerosis

- Screen for hearing loss in infants and children and determine the need for a referral to an audiologist

POTENTIAL DIAGNOSIS

If findings are normal the patient should have normal hearing. The test is conducted using earphones and/or a device placed behind the ear to deliver sounds of varying intensities. Results are categorized using ranges of pure tone recorded in decibels.

ASHA Category	Pure Tone Averages
Normal range or no impairment	-10–15 dB
Slight loss	16–25 dB
Mild loss	26–40 dB
Moderate loss	41–55 dB
Moderately severe loss	56–70 dB
Severe loss	71–90 dB
Profound loss	Greater than 91 dB

dB = decibel.

Normal findings in

- Normal pure tone average of -10 to 15 dB for infants, children, or adults

Abnormal findings in

- Causes of conductive hearing loss
 - Impacted cerumen
 - Hole in eardrum
 - Malformed outer ear, ear canal, or middle ear
 - Obstruction of external ear canal (*related to presence of a foreign body*)
 - Otitis externa (*related to infection in ear canal*)
 - Otitis media (*related to poor eustachian tube function or infection*)
 - Otitis media serous (*related to fluid in middle ear due to allergies or a cold*)
 - Otosclerosis

- Causes of sensorineural hearing loss

Congenital damage or malformations of the inner ear

Ménière's disease

Ototoxic drugs administered orally, topically, as otic drops, by IV, or passed to the fetus in utero (*aminoglycoside antibiotics, e.g., gentamicin or tobramycin, and chemotherapeutic drugs, e.g., cisplatin and carboplatin, are known to cause permanent hearing loss; quinine, loop diuretics, and salicylates, e.g., aspirin are known to cause temporary hearing loss; other categories of drugs known to be ototoxic include anesthetics, cardiac medications, mood altering medications, and glucocorticosteroids, e.g., cortisone, steroids*)

Presbycusis (*gradual hearing loss experienced in advancing age related to degeneration of the cochlea*)

Serious infections (*meningitis, measles, mumps, other viral, syphilis*)

Trauma to the inner ear (*related to exposure to noise in excess of 90 dB or as a result of physical trauma*)

Tumor (*e.g., acoustic neuroma, cerebellopontine angle tumor, meningioma*)

Vascular disorders

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Effects of ototoxic medications can cause temporary, intermittent, or permanent hearing loss.
- Failure to follow pretesting preparations before the procedure may cause the procedure to be canceled or repeated.
- Improper earphone fit or audiometer calibration can affect results.
- Inability of the patient to cooperate or remain still during the

procedure because of age, language barriers, significant pain, or mental status may interfere with the test results.

- Noisy environment or extraneous movements can affect results.
- Tinnitus or other sensations can cause abnormal responses.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient/caregiver this procedure can assist in detecting hearing loss.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens.
- ▶ Obtain a history of the patient's known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and other tests and procedures to assess and diagnose auditory deficit.
- ▶ Obtain a history of the patient's symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that an audiologist or health-care provider (HCP) specializing in this procedure performs the test in a quiet, soundproof room, and that the test can take up to 20 min to evaluate both ears. Explain that each ear will be tested separately by using earphones and/or a device placed behind the ear to deliver sounds of varying intensities. Address concerns about claustrophobia, as appropriate.

Explain and demonstrate to the patient how to communicate with the audiologist and how to exit from the room.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Ensure that the external auditory canal is clear of impacted cerumen.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Perform otoscopy examination to ensure that the external ear canal is free from any obstruction (see monograph titled "Otoscopy").
- ▶ Test for closure of the canal from the pressure of the earphones by compressing the tragus. Tendency for the canal to close (often the case in children and elderly patients) can be corrected by the careful insertion of a small stiff plastic tube into the anterior canal.
- ▶ Place the patient in a sitting position in comfortable proximity to the audiometer in a soundproof room. The ear not being tested is masked to prevent crossover of test tones, and the earphones are positioned on the head and over the ear canals. Infants and children may be tested using earphones that are inserted into the ear, unless contraindicated. An oscillating probe may be placed over the mastoid process behind the ear or on the forehead if bone conduction testing is to

be performed as part of the hearing assessment.

- ▶ Start the test by providing a trial tone of 15 to 20 dB above the expected threshold to the ear for 1 to 2 sec to familiarize the patient with the sounds. Instruct the patient to press the button each time a tone is heard, no matter how loudly or faintly it is perceived. If no response is indicated, the level is increased until a response is obtained and then raised in 10-dB increments or until the audiometer's limit is reached for the test frequency. The test results are plotted on a graph called an audiogram using symbols that indicate the ear tested and responses using earphones (air conduction) or oscillator (bone conduction).

Air Conduction

- ▶ Air conduction is tested first by starting at 1,000 Hz and gradually decreasing the intensity 10 dB at a time until the patient no longer presses the button, indicating that the tone is no longer heard. The intensity is then increased 5 dB at a time until the tone is heard again. The tone is delivered to an infant through insert earphones or ear muffs, and the auditory response is measured through electrodes placed on the infant's scalp. This is repeated until the same response is achieved at a 50% response rate at the same hertz level. The threshold is derived from the lowest decibel level at which the patient correctly identifies three out of six responses to a tone at that hertz level. The test is continued for each ear, testing the better ear first, with tones delivered at 1,000 Hz; 2,000 Hz; 4,000 Hz; and 8,000 Hz, and then again at 1,000 Hz; 500 Hz; and 250 Hz to determine a second threshold. Results are recorded on a graph called an audiogram. Averaging the air conduction thresholds at the 500-Hz; 1,000-Hz; and 2,000-Hz levels reveals the degree of hearing loss and is called the pure tone average (PTA).

Bone Conduction

- ▶ Bone conduction testing is performed in a similar manner to air conduction

testing; a vibrator placed on the skull is used to deliver tones to an infant. The raised and lowered tones are delivered as in air conduction using 250 Hz; 500 Hz; 1,000 Hz; 2,000 Hz; and 4,000 Hz to determine the thresholds. An analysis of thresholds for air and bone conduction tones is done to determine the type of hearing loss (conductive, sensorineural, or mixed).

- ▶ In children between 6 mo and 2 yr of age, minimal response levels can be determined by behavioral responses to test tone. In the child 2 yr and older, play audiometry that requires the child to perform a task or raise a hand in response to a specific tone is performed. In children 12 yr and older, the child is asked to follow directions in identifying objects; response to speech of specific intensities can be used to evaluate hearing loss that is affected by speech frequencies.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual activity, as directed by the HCP.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to hearing loss or perceived loss of independence. As appropriate, instruct the patient in the use, cleaning, and storing of a hearing aid. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Profound hearing loss can have a long-range impact personally, socially, and professionally. Consideration needs to be given to support groups that may guide the patient toward a realistic transition toward life management with an auditory deficit. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Center for Hearing Assessment and Management (<http://infantheating.org>) or for the American Speech-Language-Hearing

Association (www.asha.org) or for assistive technology at ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research, www.abledata.com). When caring for a patient with altered auditory function, forms of communication should be adapted to meet the patient's needs.

The process of communication chosen should be documented on the plan of care to ensure consistency and decrease frustration.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. As appropriate, instruct the patient in the use, cleaning, and storing of a hearing aid. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include analgesic and antipyretic drugs, antimicrobial drugs, cultures bacterial (ear), evoked brain potential studies for hearing loss, gram stain, newborn screening, otoscopy, spondee speech reception threshold, and tuning fork tests (Webber, Rinne).
- ▶ Refer to the table of tests associated with the Auditory System at the end of the book.

β_2 -Microglobulin, Blood and Urine

SYNONYM/ACRONYM: β_2 -M, BMG.

COMMON USE: To assist in diagnosing malignancy such as lymphoma, leukemia, or multiple myeloma. Also valuable in assessing for chronic severe inflammatory and renal diseases.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube or 5 mL urine from a timed collection in a clean plastic container with 1 N NaOH as a preservative.

NORMAL FINDINGS: (Method: Immunochemiluminometric assay)

Sample	Conventional & SI Units
Serum	
Newborn–1 mo	1.6–4.8 mg/L
2–6 mo	1–3.8 mg/L
7–11 mo	0.9–3.1 mg/L
1–6 yr	0.6–2.4 mg/L
7–18 yr	0.7–2 mg/L
Adult	0.6–2.4 mg/L
Urine	0–300 mcg/L

DESCRIPTION: β_2 -Microglobulin (BMG) is a protein component of human leukocyte antigen (HLA) complexes. BMG is on the surface of most cells and is therefore a useful indicator of cell death or unusually high levels of cell production. BMG is a small protein and is readily reabsorbed by kidneys with normal function. BMG increases in inflammatory conditions and when lymphocyte turnover increases, such as in lymphocytic leukemia or when T-lymphocyte helper (OKT⁴) cells are attacked by HIV. Serum BMG becomes elevated with malfunctioning glomeruli but decreases with malfunctioning tubules because it is metabolized by the renal tubules. Conversely, urine BMG decreases with malfunctioning glomeruli but becomes elevated with malfunctioning tubules.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect aminoglycoside toxicity
- Detect chronic lymphocytic leukemia, multiple myeloma, lung cancer, hepatoma, or breast cancer
- Detect HIV infection (*Note:* levels do not correlate with stages of infection)
- Evaluate renal disease to differentiate glomerular from tubular dysfunction
- Evaluate renal transplant viability and predict rejection
- Monitor antiretroviral therapy

POTENTIAL DIAGNOSIS

Increased in

- AIDS (*related to increased lymphocyte turnover*)
- Aminoglycoside toxicity (*related to renal damage; urine BMG becomes elevated before creatinine*)
- Amyloidosis (*related to chronic inflammatory conditions associated with increased BMG and other acute-phase reactant proteins; also related to deposition of amyloid in joints and tissues of patients receiving long-term hemodialysis*)
- Autoimmune disorders (*related to increased lymphocyte turnover*)

- Breast cancer (*related to increased lymphocyte turnover; serum BMG indicates tumor growth rate, size, and response to treatment*)
 - Crohn's disease (*related to chronic inflammatory conditions associated with increased BMG and other acute-phase reactant proteins*)
 - Felty's syndrome (*related to chronic inflammatory conditions associated with increased BMG and other acute-phase reactant proteins*)
 - Heavy metal poisoning
 - Hepatitis (*related to increased lymphocyte turnover in response to viral infection*)
 - Hepatoma (*related to increased lymphocyte turnover; serum BMG indicates tumor growth rate, size, and response to treatment*)
 - Hyperthyroidism (*related to increased lymphocyte turnover in immune thyroid disease*)
 - Leukemia (chronic lymphocytic) (*related to increased lymphocyte turnover; serum BMG indicates tumor growth rate, size, and response to treatment*)
 - Lung cancer (*related to increased lymphocyte turnover; serum BMG indicates tumor growth rate, size, and response to treatment*)
 - Lymphoma (*related to increased lymphocyte turnover; serum BMG indicates tumor growth rate, size, and response to treatment*)
 - Multiple myeloma (*related to increased lymphocyte turnover*)
 - Poisoning with heavy metals, such as mercury or cadmium (*related to renal damage that decreases BMG absorption*)
 - Renal dialysis (*related to ability of renal tubule to reabsorb BMG*)
 - Renal disease (glomerular): serum only (*related to ability of renal tubule to reabsorb BMG*)
 - Renal disease (tubular): urine only (*related to ability of renal tubule to reabsorb BMG*)
 - Sarcoidosis
 - Sjögren's disease
 - Systemic lupus erythematosus (*related to chronic inflammatory conditions associated with increased BMG and other acute-phase reactant proteins*)
 - Vasculitis (*related to chronic inflammatory conditions associated with increased BMG and other acute-phase reactant proteins*)
 - Viral infections (e.g., cytomegalovirus) (*related to increased lymphocyte turnover*)
- Decreased in**
- Renal disease (glomerular): urine only
 - Renal disease (tubular): serum only
 - Response to zidovudine (AZT) (*related to decreased viral replication and lymphocyte destruction*)
- CRITICAL FINDINGS:** N/A
- INTERFERING FACTORS**
- Drugs and proteins that may increase serum BMG levels include cyclosporin A, gentamicin, interferon alfa, and lithium.
 - Drugs that may decrease serum BMG levels include zidovudine.
 - Drugs that may increase urine BMG levels include azathioprine, cisplatin, cyclosporin A, furosemide, gentamicin, iodixanol, iopentol, mannitol, nifedipine, sisomicin, and tobramycin.
 - Urinary BMG is unstable at pH less than 5.5.

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
<p>Fatigue (Related to metastatic disease; tumor; pain; radiation therapy; chemotherapy; anemia; insufficient nutrition; anxiety)</p> <p>Spirituality (Related to diagnosis of terminal illness; active dying; ongoing chronic illness; anxiety; fear; hopelessness)</p>	<p>Report of tiredness; inability to maintain activities of daily living at current level; inability to restore energy after rest or sleep</p> <p>Disharmony between personal beliefs, value system, and threat to life; anger; lack of courage; no purpose or meaning to life; lack of acceptance of diagnosis, disease process; separation from support system; disinterest in connecting with others</p>	<p>Discuss the implementation of energy conservation activities (even pace when working, frequent rest periods, frequent items in easy reach, push items instead of pulling); limit naps to increase nighttime sleeping; set priorities for energy expenditures; order transfusion of ordered blood or blood products to treat anemia; administer ordered psychostimulants as appropriate; encourage participation in ordered psychotherapy</p> <p>Assess for the presence of religious affiliation; assess cultural factors that influence spirituality; encourage verbalization of feelings; work proactively to develop a positive relationship with the patient; assist decision-making working within patient's value system; facilitate interaction with religious leaders; support faith-based rituals</p>

(table continues on page 194)

Problem	Signs & Symptoms	Interventions
<p>Infection (Related to altered immune response associated with chemotherapy and radiation therapy; opportunistic hosts)</p>	<p>Fever; evidence of local or systemic infection; blood cultures positive for infection; sputum culture positive for infection; increased heart rate and respiratory rate; chills; change in mental status; fatigue; malaise; weakness; anorexia; headache; nausea; elevated blood glucose; hypotension; diminished oxygen saturation; elevated WBC; elevated C-reactive protein</p>	<p>Provide standard precautions in the provision of care; correlate symptoms with laboratory values and disease process; trend vital signs and laboratory values to monitor for improvement; administer prescribed antibiotics and medications for fever reduction; educate patient and family measures; be vigilant with hand hygiene; educate patient and family regarding good hand hygiene; infuse ordered IV fluids to support adequate hydration; ensure implementation of infection prevention measures with consideration of age and culture such as adequate nutrition; perform aseptic wound care; ensure skin care; ensure oral care; ensure adequate rest; avoid exposure to opportunistic hosts; send cultures to the laboratory as ordered; correlate culture findings with selected antibiotics; avoid mouthwashes with high alcohol content; notify health-care provider (HCP) of temperature spikes or flu-like symptoms; discuss implementation of protective isolation for neutrophil count less than 500 to $1,000 \times 10^3/\text{microl}$</p>
<p>Bleeding (Related to altered bone marrow function secondary to radiation therapy and chemotherapy)</p>	<p>Decreased platelet count; altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; capillary refill greater than three seconds; cool extremities</p>	<p>Administer prescribed platelets or blood as ordered; monitor and trend platelet count; increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer stool softeners as needed; monitor stool for blood; encourage intake of foods rich in vitamin K; monitor and trend HGB/HCT; assess skin for petechiae, purpura, hematoma; monitor for blood in emesis or sputum; institute bleeding precautions (prevent unnecessary venipuncture; avoid IM injections; prevent trauma; be gentle with oral care, suctioning; avoid use of a sharp razor); coordinate lab draws to decrease number of sticks; review transfusion reaction symptoms</p>

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that the test is used to evaluate renal disease, AIDS, and certain malignancies.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, are important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

Blood

- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

Urine

- ▶ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
- ▶ Usually, a 24-hr urine collection is ordered. Inform the patient that all urine over a 24-hr period must be saved; instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom as a reminder to save all urine.
- ▶ Instruct the patient to void all urine into the collection device and then pour the urine into the laboratory collection container. Alternatively, the specimen

can be left in the collection device for a health-care staff member to add to the laboratory collection container.

INTRATEST:**Potential Complications:** N/A

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the venipuncture.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture as appropriate.

Blood

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation, and secure gauze with adhesive bandage.

Urine

- ▶ Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- ▶ If possible, begin the test between 6 and 8 a.m. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. At the same time the next morning, ask the patient to void and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty

the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection started.

- ▶ Compare the quantity of urine with the urinary output record for the collection at the conclusion of the test. If the specimen contains less than what was recorded as output, some urine may have been discarded, thus invalidating the test.

Blood or Urine

- ▶ Promptly transport the specimen to the laboratory for processing and analysis. Include on the urine specimen label the amount of urine and ingestion of any medications that can affect test results.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Stress the importance of good nutrition, and suggest that the patient meet with a nutritional specialist. Also, stress the importance of following the care plan for medications and follow-up visits.
- ▶ **Social and Cultural Considerations:** Recognize anxiety related to test results, and be supportive of impaired activity related to weakness, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for AIDS information provided by the National Institutes of Health (www.aidsinfo.nih.gov).
- ▶ **Social and Cultural Considerations:** Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen.
- ▶ **Social and Cultural Considerations:** Offer support, as appropriate, to patients who may be the victims of rape or sexual assault.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Educate the patient regarding the risk of infection related to immunosuppressed inflammatory response and fatigue related to decreased energy production.
- ▶ Educate the patient regarding access to counseling services.
- ▶ Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained.
- ▶ Discuss emotional problems the patient may experience (e.g., guilt, depression, anger).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Inform the patient that retesting may be necessary.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding of the normal range of a platelet count
- ▶ States understanding of the rationale for bleeding precautions to overall health

Skills

- ▶ Demonstrates proficient use of nasal spray and lip lubricant to decrease cracking and bleeding
- ▶ Demonstrates proficiency in protecting self from injury and trauma with associated bleeding risk

Attitude

- ▶ Complies with the request for type and cross match for possible platelet transfusion
- ▶ Complies with recommendation to attend support groups to assist with managing end-of-life concerns

RELATED MONOGRAPHS:

▶ Related tests include antimicrobial drugs, ANA, barium enema, biopsy (bone marrow, biopsy breast, biopsy liver, biopsy lung, biopsy lymph node), BUN, capsule endoscopy, CD4/CD8 enumeration, colonoscopy, CRP, cancer antigens, CBC, creatinine, cultures (mycobacteria, sputum, viral), cytology sputum, CMV, ESR, gallium scan, GGT, hepatitis antigens and antibodies (A, B, C), HIV-1/HIV-2 serology,

immunofixation electrophoresis, immunoglobulins (A, G, and M), liver and spleen scan, lymphangiogram, MRI breast, mammogram, microalbumin, osmolality, protein total and fractions, renogram, RF, stereotactic breast biopsy, TB tests, US (breast, liver, lymph node), and UA.

▶ Refer to the Genitourinary and Immune systems tables at the end of the book for related tests by body system.

Barium Enema

SYNONYM/ACRONYM: Air-contrast barium enema, double-contrast barium enema, lower GI series, BE.

COMMON USE: To assist in diagnosing bowel disease in the colon such as tumors and polyps.

AREA OF APPLICATION: Colon.

CONTRAST: Barium sulfate, air, iodine mixture.

DESCRIPTION: This radiological examination of the colon, distal small bowel, and occasionally the appendix follows instillation of barium (single contrast study) using a rectal tube inserted into the rectum or an existing ostomy; the patient retains the contrast while a series of images are obtained. Visualization can be improved by draining the barium and using air contrast (double contrast study). Some of the barium remains on the surface of the colon wall, allowing for greater detail in the images. A combination of x-ray and fluoroscopic techniques are used to complete the study. This test is especially useful in the evaluation of patients experiencing lower abdominal pain, changes in bowel

habits, or the passage of stools containing blood or mucus, and for visualizing polyps, diverticula, and tumors. A barium enema may be therapeutic by reducing an obstruction caused by intussusception, or telescoping of the small intestine into the large intestine; this is a condition that most commonly affects children.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients with suspected perforation of the colon should

receive a water-soluble iodinated contrast medium, such as Gastrografin, to prevent barium from spilling into the retroperitoneum and causing an inflammatory reaction in the surrounding tissue.

- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Uncooperative patients who may not be able to retain the barium for imaging
- ◆ Patients with conditions such as rapid heart rate, intestinal obstruction, megacolon, acute ulcerative colitis, acute diverticulitis, or suspected rupture of the colon; **barium or water from the enema may make the condition worse**

INDICATIONS

- Determine the cause of rectal bleeding, blood, pus, or mucus in feces

- Evaluate suspected inflammatory process, congenital anomaly, motility disorder, or structural change
- Evaluate unexplained weight loss, anemia, or a change in bowel pattern
- Identify and locate benign or malignant polyps or tumors

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, filling, shape, position, and motility of the colon
- Normal filling of the appendix and terminal ileum

Abnormal findings in

- Appendicitis
- Colorectal cancer
- Congenital anomalies
- Crohn's disease
- Diverticular disease
- Fistulas
- Gastroenteritis
- Granulomatous colitis
- Hirschsprung's disease
- Intussusception
- Perforation of the colon
- Polyps
- Sarcoma
- Sigmoid torsion
- Sigmoid volvulus
- Stenosis
- Tumors
- Ulcerative colitis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field (e.g., jewelry, body rings).

- Improper adjustment of the radiographic equipment to accommodate obese or thin patients.
- Incorrect patient positioning, which may produce poor visualization of the area to be examined.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Spasm of the colon, which can mimic the radiographic signs of cancer. (*Note:* The use of intravenous glucagon minimizes spasm.)
- Inability of the patient to tolerate introduction of or retention of barium, air, or both in the bowel.
- Residual stool in the colon, which can obscure visualization of the bowel wall and can mimic a polyp.

Other considerations

- Barium enema should be performed before an upper gastrointestinal (GI) study or barium swallow to avoid retention of residual barium which may obscure details of interest.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/)

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the area during the examination should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the colon.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Verify that this procedure is performed before an upper GI study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium (e.g., Gastrografin) is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily

impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).

- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is performed in a radiology department, by an HCP specializing in this procedure, with support staff, and takes approximately 30 min.

Pediatric Considerations Preparing children for a barium enema depends on the age of the child. Encourage parents to be truthful about unpleasant sensations (cramping, pressure, fullness) the child may experience during the procedure and to use words that they know their child will understand. Toddlers and preschool-age children have a very short attention span, so the

best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with them during the procedure. Explain that there will be monitors in the room and they will be able to watch their procedure along with their health-care team.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to eat a low-residue diet for several days before the procedure and to consume only clear liquids the evening before the test. The patient should fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities. Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution's policy.

Pediatric Preps

≤2 years	Clear liquid diet 24 hr prior to the procedure; a pediatric Fleet enema [a half or whole suppository (glycerin or Dulcolax) may be ordered instead of the enema] on the evening prior to and morning of the procedure up to 3 h prior to the procedure; NPO for 4 hr before procedure
3–16 years	<ul style="list-style-type: none"> • Low residue diet for 48 hr prior to procedure • Clear liquid diet for 24 hr prior to procedure; castor oil or Neoloid, a flavored castor oil, may be ordered the night before the procedure; dose is based either on weight or age—for castor oil, 26–80 pounds give 1 ounce, 81 pounds or greater give 2 ounces; for Neoloid, 2–5 years give 2 teaspoons, 6–8 years give 1 tablespoon, 8–18 years give 2 tablespoons—or Dulcolax oral tablet may be substituted based on age (3–8 years give 1 tablet, age 9 years and older give 2 tablets) • Fleet enemas, until fecal return is clear, up to 3 hr prior to procedure • NPO for 4 hr prior to procedure

- ▶ Patients with a colostomy will be ordered special preparations and colostomy irrigation.
- ▶ Instruct the patient to remove all metallic objects from the area of the procedure as the metal may impair clear imaging.

INTRATEST:

Potential Complications:

Complications include allergic reaction (**related to contrast reaction**), abdominal discomfort and cramping

(related to retention of barium), peritonitis (related to leakage of barium into the peritoneal cavity, perforation of the colon or hemorrhage, resulting from changes in hydrostatic pressure during administration of the enema or manipulations of the tip of the enema tubing during barium administration to patients with a weak colon; a rare complication that may occur in children, immunocompromised patients, or patients whose colon is already weakened by disease), and constipation, fecal impaction, or bowel obstruction (related to dehydration and/or retained barium).

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Assess for completion of bowel preparation according to the institution's procedure.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided. **Geriatric Considerations** Elderly patients present with a variety of concerns when undergoing diagnostic procedures. Level of cooperation and fall risk may be complicated by underlying problems such as visual and hearing impairment, joint and muscle stiffness, physical weakness, mental confusion, and the effects of medications. A fall injury can be avoided by providing assistance getting on and off the x-ray table and on and off the toilet at the end of the exam. Elderly patients are often chronically dehydrated; anticipating the effects of hypovolemia and orthostasis can also help prevent falls.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the

procedure because movement produces unreliable results.

- ▶ Place the patient in the supine position on an examination table and take an initial image.
- ▶ Instruct the patient to lie on his or her left side (Sims' position). A rectal tube is inserted into the anus and an attached balloon is inflated after it is situated against the anal sphincter. **Geriatric and Pediatric Considerations** Reduced muscle tone occurs with advanced age, and fully developed muscle tone may not be present in children. Therefore, elderly patients and children may have difficulty holding the barium in the colon while the images are taken. The balloon tip is used to assist with retention of the barium.
- ▶ Barium is instilled into the colon by gravity, and its movement through the colon is observed by fluoroscopy.
- ▶ For patients with a colostomy, an indwelling urinary catheter is inserted into the stoma and barium is administered.
- ▶ Images are taken with the patient in different positions to aid in the diagnosis.
- ▶ If a double-contrast barium enema has been ordered, air is then instilled in the intestine and additional images are taken.
- ▶ After the procedure most of the barium is removed using the rectal tube. The patient is helped to the bathroom to expel residual barium or placed on a bedpan if unable to ambulate.
- ▶ A postevacuation image is taken of the colon to verify expulsion of the barium.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, medications, or activity, as directed by the HCP.
- ▶ Instruct the patient to take a mild laxative and increase fluid intake (four 8-oz glasses) to aid in elimination of barium, unless contraindicated. **Pediatric Considerations** Instruct the parents of pediatric patients to hydrate the child

with electrolyte fluid post barium enema. **Geriatric Considerations** Chronic dehydration can also result in frequent bouts of constipation.

Therefore, after the procedure, elderly patients should be encouraged to hydrate with fluids containing electrolytes (e.g., Gatorade, Gatorade low calorie, for diabetics, or Pedialyte) and to use a mild laxative daily until the stool is back to normal color.

- ▶ Carefully monitor the patient for fatigue and fluid and electrolyte imbalance.
- ▶ Instruct the patient that stools will be white or light in color for 2 to 3 days. If the patient is unable to eliminate the barium, or if stools do not return to normal color, the patient should notify the HCP.
- ▶ Advise patients with a colostomy that tap water colostomy irrigation may aid in barium removal.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and

frequency of occult blood testing, colonoscopy, or other cancer screening procedures should be made after consultation between the patient and HCP. The most current guidelines for colon cancer screening of the general population as well as individuals with increased risk are available from the American Cancer Society (www.cancer.org) and the American College of Gastroenterology (www.gi.org). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include cancer antigens, colonoscopy, colposcopy, CT abdomen, fecal analysis, MRI abdomen, PET pelvis, and proctosigmoidoscopy.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Barium Swallow

SYNONYM/ACRONYM: Esophagram, video swallow, esophagus x-ray, swallowing function, esophagraphy.

COMMON USE: To assist in diagnosing disease of the esophagus such as stricture or tumor.

AREA OF APPLICATION: Esophagus.

CONTRAST: Barium sulfate, water-soluble iodinated contrast.

DESCRIPTION: This radiological examination of the esophagus evaluates motion and anatomic structures of the esophageal lumen by recording images of the lumen

while the patient swallows a barium solution of milkshake consistency and a chalky taste. The procedure is a dynamic study and uses fluoroscopic and

cineradiographic techniques. A dynamic study is one in which there is continuous monitoring of the motion being studied as opposed to a static study in which the patient and equipment are held in one position until the image has been taken. The barium swallow is often performed as part of an upper gastrointestinal (GI) series or cardiac series and is indicated for patients with a history of dysphagia and gastric reflux. The standard barium swallow study focuses on the esophageal structures of the GI tract and may identify reflux of the barium from the stomach back into the esophagus. Muscular abnormalities such as achalasia, as well as diffuse esophageal spasm, can be easily detected with this procedure. Gastroesophageal reflux disease (GERD) is a disorder of the gastrointestinal system commonly seen in the elderly. Because of the physiological changes associated with the aging process, numerous factors come into play that negatively impact quality of life and contribute to the development of significant complications in elderly patients as a result of GERD.

The **modified barium swallow** focuses on the oropharyngeal structures and is also used to evaluate dysphagia, or difficulty swallowing. The test may be performed and observed in the presence of a radiologist and radiology technician with or without a feeding specialist or speech pathologist depending on the reason for the examination. Nurses will encounter patients who struggle with swallowing disorders in different settings such as intensive care units, nurseries, rehabilitative units, or skilled nursing units. Situations that might indicate a modified

barium swallow include the evaluation of a patient's ability to swallow food after a stroke or the inability of a child to swallow food of varying consistencies without gagging and choking during feeding.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients who are unable to cooperate by swallowing upon request
- ◆ Patients with an obstruction, ulcer, or suspected esophageal rupture, unless water-soluble iodinated contrast medium, such as Gastrografin, is used
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients

who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

-  Patients with severe constipation or bowel obstruction, as barium may make the condition worse
-  Patients with a severe swallowing disorder *to the extent that aspiration might occur*
-  Patients with suspected tracheoesophageal fistula, unless barium is used

INDICATIONS

- Confirm the integrity of esophageal anastomoses in the postoperative patient
- Detect esophageal reflux, tracheoesophageal fistulas, and varices
- Determine the cause of dysphagia or heartburn
- Determine the type and location of foreign bodies within the pharynx and esophagus
- Evaluate suspected esophageal motility disorders
- Evaluate suspected polyps, strictures, Zenker's diverticula, tumor, or inflammation

POTENTIAL DIAGNOSIS

Normal findings in

- Normal peristalsis through the esophagus into the stomach with normal size, filling, patency, and shape of the esophagus

Abnormal findings in

- Achalasia
- Acute or chronic esophagitis
- Benign or malignant tumors
- Chalasias
- Diverticula
- Esophageal ulcers
- Esophageal varices
- Hiatal hernia
- Perforation of the esophagus
- Strictures or polyps

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects within the examination field.
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure.
- Incorrect patient positioning, which may produce poor visualization of the area to be examined.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Ensure that the procedure is done after cholangiography and barium enema.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/)
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the esophagus.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that this procedure is performed before an upper GI study or video swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note that if iodinated contrast medium (e.g., Gastrografin) is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin (**related to renal impairment that does not support sufficient excretion of metformin**).
- ▶ Explain to the patient that some pain may be experienced during the test, and there may be moments of discomfort. Review the procedure with the patient and explain the need to swallow a barium contrast medium. Inform the patient that the procedure is performed in a radiology department by a HCP and takes approximately 15 to 30 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important

in providing psychological support before, during, and after the procedure.

- ▶ Instruct the patient to remove all external metallic objects from the area to be examined.

- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities.

Pediatric Considerations The fasting period prior to the time of the examination depends on the child's age. General guidelines are as follows: birth to 6 months, 3 hr; 7 months to 2 years, 4 hr; 3 years and older, 6 hr.

INTRATEST:

Potential Complications:

- While complications are rare, they may include allergic reaction (**related to contrast reaction**), constipation, impaction, or bowel obstruction (**related to retained barium**), and aspiration of barium (**related to extreme swallowing disorders**).
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure the patient has complied with dietary and fluid restrictions for 8 hr prior to the procedure.
 - ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
 - ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
 - ▶ Instruct the patient to cooperate and follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
 - ▶ Instruct the patient to stand in front of the x-ray fluoroscopy screen. Place the patient supine on the radiographic table if he or she is unable to stand.
 - ▶ An initial image is taken, and the patient is asked to swallow a barium solution with or without a straw.
 - ▶ Multiple images at different angles may be taken.
 - ▶ The patient may be asked to drink additional barium to complete the

study. Swallowing the additional barium evaluates the passage of barium from the esophagus into the stomach.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ Carefully monitor the patient for fatigue and fluid and electrolyte imbalance.
- ▶ Instruct the patient to take a mild laxative and increase fluid intake (four 8-oz glasses) to aid in elimination of barium, unless contraindicated. **Pediatric Considerations** Instruct the parents of pediatric patients to hydrate children with electrolyte fluids post barium swallow.
- ▶ **Geriatric Considerations** Chronic dehydration can also result in frequent bouts of constipation. Therefore, after the procedure, elderly patients should be encouraged to use a mild laxative daily until the stool is back to normal color.
- ▶ Instruct the patient that stools will be white or light in color for 2 to 3 days. If the patient is unable to eliminate the barium, or if stools do not return to

normal color, the patient should notify the requesting HCP.

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include capsule endoscopy, chest x-ray, CT thoracic, endoscopy, esophageal manometry, gastroesophageal reflux scan, MRI chest, and thyroid scan.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Bilirubin and Bilirubin Fractions

SYNONYM/ACRONYM: Conjugated/direct bilirubin, unconjugated/indirect bilirubin, delta bilirubin, TBil.

COMMON USE: A multipurpose lab test that acts as an indicator for various diseases of the liver or for disease that affects the liver.

SPECIMEN: Serum (1 mL) collected in gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in green-top (heparin) tube or in a heparinized microtainer is also acceptable. Protect sample from direct light.

NORMAL FINDINGS: (Method: Spectrophotometry) Total bilirubin levels in infants should decrease to adult levels by day 10 as the development of the hepatic circulatory system matures. Values in breastfed infants may take longer to reach normal adult levels. Values in premature infants may initially be higher than in full-term infants and also take longer to decrease to normal levels.

Age	Conventional Units	SI Units (Conventional Units × 17.1)
Total bilirubin		
Newborn—1 day	Less than 5.8 mg/dL	Less than 99 micromol/L
1–2 days	Less than 8.2 mg/dL	Less than 140 micromol/L
3–5 days	Less than 11.7 mg/dL	Less than 200 micromol/L
6–7 days	Less than 8.4 mg/dL	Less than 144 micromol/L
8–9 days	Less than 6.5 mg/dL	Less than 111 micromol/L
10–11 days	Less than 4.6 mg/dL	Less than 79 micromol/L
12–13 days	Less than 2.7 mg/dL	Less than 46 micromol/L
14–30 days	Less than 0.8 mg/dL	Less than 14 micromol/L
1 mo—older adult	Less than 1.2 mg/dL	Less than 21 micromol/L
Unconjugated bilirubin	Less than 1.1 mg/dL	Less than 19 micromol/L
Conjugated bilirubin		
Neonate	Less than 0.6 mg/dL	Less than 10 micromol/L
29 days—older adult	Less than 0.3 mg/dL	Less than 5 micromol/L
Delta bilirubin	Less than 0.2 mg/dL	Less than 3 micromol/L

DESCRIPTION: Bilirubin is a by-product of heme catabolism from aged red blood cells (RBCs). Bilirubin is primarily produced in the liver, spleen, and bone marrow. Total bilirubin is the sum of unconjugated or indirect bilirubin, monoglucuronide and diglucuronide, conjugated or direct bilirubin, and albumin-bound delta bilirubin. Unconjugated bilirubin is carried to the liver by albumin, where it becomes conjugated. In the small intestine, conjugated bilirubin converts to urobilinogen and then to urobilin. Urobilin is then excreted in the feces. Defects in bilirubin excretion can be identified in a routine urinalysis. Increases in bilirubin levels can result from prehepatic, hepatic, and/or posthepatic conditions, making fractionation useful in determining the cause of the increase in total bilirubin levels. Delta bilirubin has a longer half-life than the other bilirubin fractions and therefore remains

elevated during convalescence after the other fractions have decreased to normal levels. Delta bilirubin can be calculated using the formula:

$$\text{Delta bilirubin} = \text{Total bilirubin} - (\text{Indirect bilirubin} + \text{Direct bilirubin})$$

When bilirubin concentration increases, the yellowish pigment deposits in skin and sclera. This increase in yellow pigmentation is termed *jaundice* or *icterus*. Bilirubin levels can also be checked using noninvasive methods. Hyperbilirubinemia in neonates can be reliably evaluated using transcutaneous measurement devices.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the differential diagnosis of obstructive jaundice

- Assist in the evaluation of liver and biliary disease
- Monitor the effects of drug reactions on liver function
- Monitor the effects of phototherapy on jaundiced newborns
- Monitor jaundice in newborn patients

POTENTIAL DIAGNOSIS

Increased in

- Prehepatic (hemolytic) jaundice (*related to excessive amounts of heme released from RBC destruction. Heme is catabolized to bilirubin in concentrations that exceed the liver's conjugation capacity, and indirect bilirubin accumulates*)
Erythroblastosis fetalis
Hematoma
Hemolytic anemia
Pernicious anemia
Physiological jaundice of the newborn
The post blood transfusion period, when a number of units are rapidly infused or in the case of a delayed transfusion reaction
RBC enzyme abnormalities (i.e., glucose-6-phosphate dehydrogenase, pyruvate kinase, spherocytosis)
- Hepatic jaundice (*related to bilirubin conjugation failure*)
Crigler-Najjar syndrome
- Hepatic jaundice (*related to disturbance in bilirubin transport*)
Dubin-Johnson syndrome (*related to preconjugation transport failure*)
Gilbert's syndrome (*related to postconjugation transport failure*)
- Hepatic jaundice (*evidenced by liver damage or necrosis that interferes with excretion into bile ducts either by physical obstruction or drug inhibition and bilirubin accumulates*)
Alcoholism
Cholangitis
Cholecystitis
Cholestatic drug reactions

- Cirrhosis
- Hepatitis
- Hepatocellular damage
- Infectious mononucleosis
- Posthepatic jaundice (*evidenced by blockage that interferes with excretion into bile ducts, resulting in accumulated bilirubin*)
Advanced tumors of the liver
Biliary obstruction
- Other conditions
Anorexia or starvation (*related to liver damage*)
Hypothyroidism (*related to effect on the liver whereby hepatic enzyme activity for formation of conjugated or direct bilirubin is enhanced in combination with decreased flow of bile and secretion of bile acids; results in accumulation of direct bilirubin*)
Premature or breastfed infants (*evidenced by diminished hepatic function of the liver in premature infants; related to inability of neonate to feed in sufficient quantity. Insufficient breast milk intake results in weight loss, decreased stool formation, and decreased elimination of bilirubin*)

Decreased in: N/A

CRITICAL FINDINGS

Adults and children

- Greater than 15 mg/dL (SI: Greater than 257 micromol/L)

Newborns

- Greater than 13 mg/dL (SI: Greater than 222 micromol/L)

Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms.

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is

a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Sustained hyperbilirubinemia can result in brain damage. Kernicterus refers to the deposition of bilirubin in the basal ganglia and brainstem nuclei. There is no exact level of bilirubin that puts infants at risk for developing kernicterus. Symptoms of kernicterus in infants include lethargy, poor feeding, upward deviation of the eyes, and seizures. Intervention for infants may include early frequent feedings to stimulate gastrointestinal motility, phototherapy, and exchange transfusion.

INTERFERING FACTORS

- Drugs that may increase bilirubin levels by causing cholestasis include anabolic steroids, androgens, butaperazine, chlorothiazide, chlorpromazine, chlorpropamide, cinchophen, dapsone, dienoestrol, erythromycin, estrogens, ethionamide, gold salts, hydrochlorothiazide, icterogenin, imipramine, iproniazid, isocarboxazid, isoniazid, meprobamate, mercaptopurine, meropenem, methandriol, nitrofurans, norethandrolone, nortriptyline, oleandomycin, oral contraceptives, penicillins, phenothiazines,
- prochlorperazine, progesterone, promazine, promethazine, propoxyphene, protriptyline, sulfonamides, tacrolimus, thiouracil, tolazamide, tolbutamide, thiacetazone, trifluoperazine, and trimeprazine.
- Drugs that may increase bilirubin levels by causing hepatocellular damage include acetaminophen (toxic), acetylsalicylic acid, allopurinol, aminothiazole, anabolic steroids, asparaginase, azathioprine, azithromycin, carbamazepine, carbutamide, chloramphenicol, clindamycin, clofibrate, chlorambucil, chloramphenicol, chlordan, chloroform, chlorzoxazone, clonidine, colchicine, coumarin, cyclophosphamide, cyclopropane, cycloserine, cyclosporine, dactinomycin, danazol, desipramine, dexfenfluramine, diazepam, diethylstilbestrol, dinitrophenol, enflurane, ethambutol, ethionamide, ethoxazone, factor IX complex, felbamate, flavaspidic acid, flucytosine, fusidic acid, gentamicin, glycopyrrolate, guanoxan, haloperidol, halothane, hycanthone, hydroxyacetamide, ibuprofen, interferon, interleukin-2, isoniazid, kanamycin, labetalol, levamisole, lincomycin, melphalan, mesoridazine, metahexamide, metaxalone, methotrexate, methoxsalen, methyl dopa, nitrofurans, oral contraceptives, oxamniquine, oxyphenisatin, pemoline, penicillin, perphenazine, phenazopyridine, phenelzine, phenindione, pheniprazine, phenothiazines, piroxicam, probenecid, procainamide, pyrazinamide, quinine, sulfonyleureas, thiothixene, timolol, tobramycin, tolcapone, tretinoin, trimethadione, urethan, and verapamil.
- Drugs that may increase bilirubin levels by causing hemolysis include aminopyrine, amphotericin B,

carbamazepine, cephaloridine, cephalothin, chloroquine, dimercaprol, dipyrone, furadaltone, furazolidone, mefenamic acid, melphalan, mephenytoin, methylene blue, nitrofurans, nitrofurazone, pamaquine, penicillins, pentaquine, phenylhydrazine, piperazine, pipobroman, primaquine, procainamide, quinacrine, quinidine, quinine, stibophen, streptomycin, sulfonamides, triethylenemelamine, tyrothricin, and vitamin K.

- Drugs that may decrease bilirubin levels include anticonvulsants, barbiturates (newborns), chlorophenothane, cyclosporine, flumecinolone (newborns), and salicylates.
- Bilirubin is light sensitive. Therefore, the collection container should be suitably covered to protect the specimen from light between the time of collection and analysis.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Body image (<i>Related to jaundice; ascites; dry flaky itchy skin</i>)	Yellowing of sclera and skin, open sores due to aggressive itching; repeated self-criticism; refusal to discuss altered physical appearance; withdrawal from social situations; conceals physical self with clothing	Assess skin for patches of itching; monitor liver function tests; monitor bilirubin levels; assess for yellowing of the sclera and skin; provide mitts to decrease scratching; assess patient's perception of self related to current medical status; monitor for self-criticism; acknowledge normal response to changed appearance
Nutrition (<i>Related to poor eating habits; excessive alcohol use; altered liver function; nausea; vomiting</i>)	Known inadequate caloric intake; weight loss; muscle wasting in arms and legs; stool that is pale or gray colored; skin that is flaky with loss of elasticity	Document food intake with possible calorie count; assess barriers to eating; consider using a food diary; monitor continued alcohol use as it is a barrier to adequate nutrition; monitor glucose levels; check daily weight; perform dietary consult with assessment of cultural food selections; consider a high-carbohydrate diet;

Problem	Signs & Symptoms	Interventions
Confusion; altered sensory perception <i>(Related to hepatic encephalopathy; acute alcohol consumption; hepatic metabolic insufficiency)</i>	Altered attention span; unable to follow directions; disoriented to person, place, time, and purpose; inappropriate affect	administer multivitamin as prescribed; administer parenteral and enteral nutrition as needed; assess liver function tests (ALT, AST, ALP, total protein, albumin, bilirubin), folic acid, glucose, thiamine, and electrolytes Monitor blood ammonia level; determine last alcohol use; assess for symptoms of hepatic encephalopathy such as confusion, sleep disturbances, incoherence; protect the patient from physical harm; administer lactulose as prescribed
Gas exchange <i>(Related to accumulation of pleural fluid, atelectasis, ventilation perfusion mismatch; altered oxygen supply)</i>	Irregular breathing pattern, use of accessory muscles; altered chest excursion; adventitious breath sounds (crackles, rhonchi, wheezes, diminished breath sounds); copious secretions; signs of hypoxia	Monitor respiratory rate and effort based on assessment of patient condition; assess lung sounds frequently; monitor for secretions; suction as necessary; perform pulse oximetry to monitor oxygen saturation; collaborate with physician to administer oxygen as needed; elevate the head of the bed 30 degrees; monitor IV fluids and avoid aggressive fluid resuscitation; monitor degree of abdominal ascites

PRETEST:

▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

▶ **Patient Teaching:** Inform the patient this test can assist in assessing liver function.

▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

▶ Obtain a history of the patient's hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

▶ Obtain a list of the patient's current medication, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

▶ Review the procedure with the patient. Inform the patient that

specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

There are several types of jaundice that may occur in the neonate and it is important to quickly determine the cause so effective treatment can be initiated.

- ▶ Physiologic jaundice occurs as a normal response to the neonate's limited ability to excrete bilirubin in the first days of life. Intervention may include early frequent feeding to stimulate gastrointestinal motility and phototherapy. This type of jaundice usually lasts 10 to 14 days, premature neonates may take up to a month, and resolves in reverse to the pattern of development with the legs looking normal first and the face remaining yellowish longer.
 - ▶ Breastfeeding jaundice is seen in breastfed neonates during the first week of life, peaking during the second or third week. It occurs due to dehydration in neonates who do not nurse well or if the mother's milk is slow to come in; the bilirubin levels are elevated relative to the decreased total fluid volume. The goal is to provide adequate fluid and nutrition to the breastfeeding neonate by providing water or formula between feedings and until the mother's milk supply is adequate. Phototherapy may also be ordered in order to accelerate the breakdown of bilirubin and prevent accumulation to dangerous levels. Skin turgor, input and output, vital signs, and number/quality of stools should be frequently
- monitored. Total bilirubin and fractions should be monitored regularly until levels decrease to normal neonatal values.
 - ▶ Breast milk jaundice is different than breastfeeding jaundice, occurs in about 2 percent of breastfed neonates after the first week of life, takes up to 12 wk to resolve, and is believed to have a familial relationship; assessment for family history is very helpful. Hyperbilirubinemia occurs due to substances in the mother's milk that interfere with development of enzymes required to break down bilirubin. The main goals are to increase fluids by more frequent feeding or additional fluids given orally or by IV and through the use of phototherapy. Fiberoptic blankets and special beds that shine light up from the mattresses are available.
 - ▶ Severe jaundice may occur as the result of an ABO or Rh incompatibility between the mother and baby. The jaundice occurs as the result of hemolysis or RBC breakdown due to the incompatibility.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
 - ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
 - ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
 - ▶ Protect the specimen from light and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased bilirubin levels may be associated with liver disease. Dietary recommendations may be indicated depending on the condition and severity of the condition. Currently, for example, there are no specific medications that can be given to cure hepatitis, but elimination of alcohol consumption and a diet optimized for convalescence are commonly included in the treatment plan. A high-calorie, high-protein, moderate-fat diet with a high fluid intake is often recommended for the patient with hepatitis. Treatment of cirrhosis is different because a low-protein diet may be in order if the patient's liver has lost the ability to process the end products of protein metabolism. A diet of soft foods may also be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be added to or reduced from the diet. Patients should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs) rather than complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention. The alcoholic patient should be encouraged to avoid alcohol and also to seek appropriate counseling for substance abuse.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Educate the patient regarding the cause of the hyperbilirubinemia. Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Recognize anxiety related to test results, and answer any questions or address any concerns voiced by the patient or family.
- ▶ Assist patient to identify coping strategies that have worked in the past to manage disease-related anxiety
- ▶ Explain the importance of adhering to scheduled laboratory appointments to monitor liver function and disease progress.
- ▶ Explain the importance of adequate fluid intake and teach the patient skin care for the neonate.

Expected Patient Outcomes:**Knowledge**

- ▶ Recognizes that jaundice may resolve with treatment of the liver disease
- ▶ Relates the importance of nutritional supplements to help prevent malnutrition

Skills

- ▶ Follows dietary recommendations to gain and maintain adequate weight
- ▶ Naturally verbalizes feelings about changed appearance in a positive manner

Attitude

- ▶ Resolves to take proactive steps to ensure positive health maintenance
- ▶ Complies with the recommendation to attend support groups to assist in adapting to changed physical appearance

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, albumin, ALP, ammonia, amylase, AMA/ASMA, α_1 -antitrypsin/phenotyping, AST, biopsy liver, cholesterol, coagulation factor assays, CBC, cholangiography percutaneous transhepatic, cholangiography post-op, CT biliary tract and liver, copper, ERCP, GGT, hepatobiliary scan, hepatitis serologies, infectious mononucleosis screen,

lipase, liver and spleen scan, protein total and fractions, PT/INR, US abdomen, US liver, and UA.

See the Hepatobiliary System table at the end of the book for related tests by body system.

Biopsy, Bladder

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing bladder cancer.

SPECIMEN: Bladder tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue) No abnormal tissue or cells.

DESCRIPTION: Biopsy is the excision of a sample of tissue that can be analyzed microscopically to determine cell morphology and the presence of tissue abnormalities. This test is used to assist in confirming the diagnosis of cancer when clinical symptoms or other diagnostic findings are suspicious. A urologist performs a biopsy of the bladder during cystoscopic examination. The procedure can be performed in the urologist's office with local anesthesia or in the operating room under general anesthesia. Samples can be obtained by fine-needle aspiration of fluid and tumor cells from the tumor site. Needle biopsies are often performed using guidance by CT scan or ultrasound. If the cystoscopic or other diagnostic imaging examinations indicate the cancer has spread outside the bladder, confirmatory samples can be obtained by surgical biopsy. After the bladder is filled with

saline for irrigation, the bladder and urethra are examined by direct and lighted visualization using a cystoscope. A sample of suspicious bladder tissue is then excised and examined macroscopically and microscopically to determine the presence of cell morphology and tissue abnormalities.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*) or an acute infection of the bladder, urethra, or prostate.

INDICATIONS

- Assist in confirmation of malignant lesions of the bladder or ureter, especially if tumor is seen by radiological examination
- Assist in the evaluation of cases in which symptoms such as hematuria persist after previous treatment

(e.g., removal of polyps or kidney stones)

- Monitor existing recurrent benign lesions for malignant changes

POTENTIAL DIAGNOSIS

- Positive findings in neoplasm of the bladder or ureter

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of bladder disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's genitourinary system, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Inform the patient that back pain and burning or pressure in the genital area may be experienced after the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered before the percutaneous biopsy to promote relaxation and reduce discomfort; general anesthesia will be administered before the open biopsy. Explain to the patient that no

pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by an HCP specializing in this procedure. The procedure usually takes about 30 to 45 min to complete.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Bleeding (**related to perforation of the bladder, a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**) or seeding of the biopsy tract with tumor cells.

- ▶ Ensure that the patient has complied with dietary restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type

of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.

Cystoscopy

- ▶ After administration of local or general anesthesia, place the patient in a lithotomy position on the examination table (with the feet up in stirrups). Drape the patient's legs. Clean the external genitalia with a suitable antiseptic solution and drape the area with sterile towels.
- ▶ Once the cystoscope is inserted, the bladder is irrigated with saline. A tissue sample is removed using a cytology brush or biopsy forceps. Catheters may be used to obtain samples from the ureter.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic

antibiotics 1 hr before incision, use antibiotics that are consistent with current guidelines specific to the procedure, and use clippers to remove hair from the surgical site if appropriate.

- ▶ After administration of general anesthesia and surgical preparation are completed, an incision is made, suspicious areas are located, and tissue samples are collected.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Instruct the patient on intake and output recording and provide appropriate measuring containers.
- ▶ Encourage fluid intake of 3,000 mL in 24 hr unless contraindicated.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report pain, chills, or fever. Assess for

infection, hemorrhage, or perforation of the bladder.

- ▶ Inform the patient that blood may be seen in the urine after the first or second postprocedural voiding.
- ▶ Instruct the patient to report any further changes in urinary pattern, volume, or appearance.

Open Biopsy

- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site.

General

- ▶ Assess for nausea, pain, and bladder spasms. Administer antiemetic, analgesic, and antispasmodic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ **Nutritional Considerations:** Recommend a nutrition consult, if necessary, as many side effects of treatment for bladder cancer such as fatigue, bowel disturbances, and weight loss can result in malnutrition and increased risk for infection.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed

medication. Encourage him or her to review corresponding literature provided by a pharmacist.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include calculus kidney stone panel, CT renal, cystometry, cystoscopy, cystourethrography voiding, IVP, KUB studies, MRI bladder, retrograde ureteropyelography, US bladder, UA, and urine bladder cancer markers.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Biopsy, Bone

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing bone cancer.

SPECIMEN: Bone tissue.

NORMAL FINDINGS: (Method: Microscopic study of bone samples) No abnormal tissue or cells.

DESCRIPTION: Biopsy is the excision of a sample of tissue that can be analyzed microscopically to determine cell morphology and the presence of tissue abnormalities. This test is used to assist in confirming the diagnosis of cancer when clinical symptoms or x-rays are suspicious. After surgical biopsy by incision to reveal the affected area, a bone biopsy is obtained. An alternative collection method is needle biopsy. There are two types of needle biopsy: fine-needle biopsy in which fluid and tumor cells are aspirated from the tumor site and core-needle biopsy in which a plug of bone is removed using a special serrated needle. The choice of biopsy method is based on the type of tumor expected, whether the tumor is benign or malignant, and the surgeon's

anticipated plan regarding removal of the tumor.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*)

INDICATIONS

- Differentiation of a benign from a malignant bone lesion
- Radiographic evidence of a bone lesion

POTENTIAL DIAGNOSIS

Abnormal findings in

- Ewing's sarcoma
- Multiple myeloma
- Osteoma
- Osteosarcoma

CRITICAL FINDINGS

- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist to establish a diagnosis of bone disease.
- ▶ Obtain a history of the patient's complaints, including a list of

known allergens, especially allergies or sensitivities to latex or anesthetics.

- ▶ Obtain a history of the patient's immune and musculoskeletal systems, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; general anesthesia will be administered prior to the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by an HCP specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 20 min to complete.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is

important in providing psychological support before, during, and after the procedure.

- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Bleeding (*related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners*) or seeding of the biopsy tract with tumor cells.

- ▶ Ensure that the patient has complied with dietary restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.

- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ After the administration of general or local anesthesia cleanse the site with an antiseptic solution and drape the area with sterile towels.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, use antibiotics that are consistent with current guidelines specific to the procedure, and use clippers to remove hair from the surgical site if appropriate.
- ▶ After administration of general anesthesia and surgical preparation are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

Needle Biopsy

- ▶ Instruct the patient to take slow, deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. A small incision is made and the biopsy needle is inserted to remove the specimen. Pressure is applied to the site for 3 to 5 min, then a sterile pressure dressing is applied.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the

importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALP, biopsy bone marrow, bone scan, calcium, CBC, cortisol, CT spine, immunofixation electrophoresis, immunoglobulins (A, G, and M), β_2 -microglobulin, MRI musculoskeletal, PTH, phosphorus, total protein and fractions, radiography bone, UA, and vitamin D.
- ▶ See the Immune and Musculoskeletal systems tables at the end of the book for related tests by body system.

Biopsy, Bone Marrow

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing hematological diseases and in identifying and staging cancers such as leukemia.

SPECIMEN: Bone marrow aspirate, bone core biopsy, marrow and peripheral smears.

NORMAL FINDINGS: (Method: Microscopic study of bone and bone marrow samples, flow cytometry) Reference ranges are subject to many variables, and therefore the laboratory should be consulted for their specific interpretation. Some generalities may be commented on regarding findings as follows:

- Ratio of marrow fat to cellular elements is related to age, with the amount of fat increasing with increasing age.
- Normal cellularity, cellular distribution, presence of megakaryocytes, and absence of fibrosis or tumor cells.
- The myeloid-to-erythrocyte ratio (M:E) is 2:1 to 4:1 in adults. It may be slightly higher in children.

Differential Parameter

Conventional Units

Erythrocyte precursors	18–32%
Myeloblasts	0–2%
Promyelocytes	2–6%
Myelocytes	9–17%
Metamyelocytes	7–25%
Bands	10–16%
Neutrophils	18–28%
Eosinophils and precursors	1–5%
Basophils and precursors	0–1%
Monocytes and precursors	1–5%
Lymphocytes	9–19%
Plasma cells	0–1%

DESCRIPTION: This test involves the removal of a small sample of bone marrow by aspiration, needle biopsy, or open surgical biopsy for a complete hematological analysis. The marrow is a suspension of blood, fat, and developing blood cells, which is evaluated for morphology and examined for all stages of maturation; iron stores; and myeloid-to-erythrocyte ratio

(M:E). Sudan black B and periodic acid–Schiff (PAS) stains can be performed for microscopic examination to differentiate the types of leukemia, although flow cytometry and cytogenetics have become more commonly used techniques for this purpose. Immunophenotyping by flow cytometry uses markers directed at specific antigens on white blood

cell membranes to provide rapid enumeration and identification of white blood cell types as well as detection of abnormal increases or decreases in specific cell lines. Cytogenetics is a specialization within the area of genetics that includes chromosome analysis or karyotyping. Bone marrow cells are incubated in culture media to increase the number of cells available for study and to allow for hybridization of the cellular DNA with fluorescent DNA probes in a technique called fluorescence in situ hybridization (FISH). The probes are designed to target areas of the chromosome known to correlate with genetic risk for a particular disease. When a suitable volume of hybridized sample is achieved, cell growth is chemically inhibited during the prophase and metaphase stages of mitosis (cell division) and cellular DNA is examined to detect fluorescence, which represents chromosomal abnormalities, in the targeted areas.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*)

INDICATIONS

- Determine marrow differential (proportion of the various types of cells present in the marrow) and M:E
- Evaluate abnormal results of complete blood count or white blood cell count with differential showing increased numbers of leukocyte precursors
- Evaluate hepatomegaly or splenomegaly
- Identify bone marrow hyperplasia or hypoplasia

- Identify infectious organisms present in the bone marrow (histoplasmosis, mycobacteria, cytomegalovirus, parvovirus inclusions)
- Monitor effects of exposure to bone marrow depressants
- Monitor bone marrow response to chemotherapy or radiation therapy

POTENTIAL DIAGNOSIS

Increased Reticulocytes

- Compensated red blood cell (RBC) loss
- Response to vitamin B₁₂ therapy

Decreased Reticulocytes

- Aplastic crisis of sickle cell anemia or hereditary spherocytosis

Increased Leukocytes

- *General associations include compensation for infectious process, leukemias, or leukemoid drug reactions*

Decreased Leukocytes

- *General associations include reduction in the marrow space as seen in metastatic neoplasm or myelofibrosis, lack of production of cells, lower production of cells as seen in the elderly, or following suppressive therapy such as chemotherapy or radiation*

Increased Neutrophils (total)

- Acute myeloblastic leukemia
- Myeloid (chronic) leukemias

Decreased Neutrophils (total)

- Aplastic anemia
- Leukemias (monocytic and lymphoblastic)

Increased Lymphocytes

- Aplastic anemia
- Lymphatic leukemia
- Lymphomas
- Lymphosarcoma
- Mononucleosis
- Viral infections

Increased Plasma Cells

- Cancer
- Cirrhosis of the liver
- Connective tissue disorders
- Hypersensitivity reactions
- Infections
- Macroglobulinemia
- Ulcerative colitis

Increased Megakaryocytes

- Hemorrhage
- Increasing age
- Infections
- Megakaryocytic myelosis
- Myeloid leukemia
- Pneumonia
- Polycythemia vera
- Thrombocytopenia

Decreased Megakaryocytes

- Agranulocytosis
- Cirrhosis of the liver
- Pernicious aplastic anemia
- Radiation therapy
- Thrombocytopenic purpura

Increased M:E

- Bone marrow failure
- Infections
- Leukemoid reactions
- Myeloid leukemia

Decreased M:E

- Anemias
- Hepatic disease
- Polycythemia vera
- Posthemorrhagic hematopoiesis

Increased Normoblasts

- Anemias
- Chronic blood loss
- Polycythemia vera

Decreased Normoblasts

- Aplastic anemia
- Folic acid or vitamin B₁₂ deficiency
- Hemolytic anemia

Increased Eosinophils

- Bone marrow cancer
- Lymphadenoma
- Myeloid leukemia

CRITICAL FINDINGS 

- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Recent blood transfusions, iron therapy, or administration of cytotoxic agents may alter test results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a

diagnosis of bone marrow and immune system disease.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's hematopoietic and immune systems, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy. Explain to the patient that any discomfort with the needle biopsy will be minimized with local anesthetics and systemic analgesics. Explain that the patient may feel some pain when the lidocaine is injected and some discomfort at the stage in the procedure when the specimen is aspirated. Inform the patient that the biopsy is performed under sterile conditions by an HCP specializing in this procedure. A needle biopsy usually takes about 20 min to complete.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food

and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Protocols may vary among facilities.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**)

- ▶ Ensure that the patient has complied with dietary restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Assist the patient to the desired position depending on the test site to be used. In young children, the most frequently chosen site is the proximal tibia. Vertebral bodies T10 through L4 are preferred in older children. In adults, the sternum or iliac crests are the preferred sites. Place the patient in

the prone, sitting, or side-lying position for the vertebral bodies; the side-lying position for iliac crest or tibial sites; or the supine position for the sternum.

Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.

- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ After the administration of local anesthesia, use clippers to remove hair from the biopsy site if appropriate, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Needle Aspiration

- ▶ The HCP will anesthetize the site with procaine or lidocaine, and then insert a needle with stylet into the marrow. The stylet is removed, a syringe attached, and a 0.5-mL aliquot of marrow withdrawn. The needle is removed, and pressure is applied to the site. The aspirate is applied to slides, and, when dry, a fixative is applied.

Needle Biopsy

- ▶ Instruct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes.
- ▶ Local anesthetic is introduced deeply enough to include periosteum. A cutting biopsy needle is introduced through a small skin incision and bored into the marrow cavity. A core needle is introduced through the cutting needle, and a plug of marrow is removed. The needles are withdrawn, and the specimen is placed in a preservative solution. Pressure is applied to the site for 3 to 5 min, and then a pressure dressing is applied.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient and family members regarding access to counseling and other supportive services. Provide contact information, if desired, for the National Marrow Donor Program (www.marrow.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up

appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be

performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy lymph node, CBC, LAP, immunofixation electrophoresis, mediastinoscopy, and vitamin B₁₂.
- ▶ Refer to the Hematopoietic and Immune systems tables at the end of the book for related tests by body system.

B

Biopsy, Breast

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in establishing a diagnosis of breast disease; in the presence of breast cancer, this test is also used to assist in evaluating prognosis and management of response to therapy.

SPECIMEN: Breast tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue for biopsy; cytochemical or immunohistochemical for estrogen and progesterone receptors, Ki67, PCNA, P53; flow cytometry for DNA ploidy and S-phase fraction; immunohistochemical or FISH for Her-2/neu) Fluorescence in situ hybridization (FISH) is a cytogenetic technique that uses fluorescent-labeled DNA probes to detect specific chromosome abnormalities. Favorable findings:

- Biopsy: no abnormal cells or tissue
- DNA ploidy: majority diploid cell population
- SPF: low fraction of replicating cells in total cell population
- Her-2/neu, Ki67, PCNA, and P53: negative to low percentage of stained cells
- Estrogen and progesterone receptors: high percentage of stained cells

DESCRIPTION: Breast cancer is the most common newly diagnosed cancer in American women. It is the second leading cause of cancer-related death. Biopsy is the excision of a sample of tissue that

can be analyzed microscopically to determine cell morphology and the presence of tissue abnormalities. Fine-needle and open biopsies of the breast have become more commonly ordered

in recent years as increasing emphasis on early detection of breast cancer has become stronger. Breast biopsies are used to assist in the identification and prognosis of breast cancer. A number of tests can be performed on breast tissue to assist in identification and management of breast cancer. **Estrogen and progesterone receptor assays (ER and PR)** are used to identify patients with a type of breast cancer that may be more responsive than other types of tumors to estrogen-deprivation (antiestrogen) therapy or removal of the ovaries. Patients with these types of tumors generally have a better prognosis. **DNA ploidy** testing by flow cytometry may also be performed on suspicious tissue. Cancer is the unchecked proliferation of tumor cells that contain abnormal amounts of DNA. The higher the grade of tumor cells, the more likely abnormal DNA will be detected. The **ploidy** (number of chromosome sets in the nucleus) is an indication of the speed of cell replication and tumor growth. Cells synthesize DNA in the S phase of mitosis. **S-phase fraction (SPF)** is an indicator of the number of cells undergoing replication. Normal tissue has a higher percentage of resting diploid cells, or cells containing two chromosomes. Aneuploid cells contain multiple chromosomes. Genes on the chromosomes are coded to produce specific proteins. **Ki67 and proliferating cell nuclear antigen (PCNA)** are examples of proteins that can be measured to indicate the degree of cell proliferation in biopsied tissue. Overexpression of a protein called **human epidermal growth factor receptor 2**

(HER-2/neu oncoprotein) is helpful in establishing histological evidence of metastatic breast cancer. Metastatic breast cancer patients with high levels of HER-2/neu oncoprotein have a poor prognosis. They have rapid tumor progression, increased rate of recurrence, poor response to standard therapies, and a lower survival rate. Herceptin (trastuzumab) is indicated for treatment of HER-2/neu overexpression. **P53** is a suppressor protein that normally prevents cells with abnormal DNA from multiplying. Mutations in the P53 gene cause the loss of P53 functionality; the checkpoint is lost, and cancerous cells are allowed to proliferate.

This procedure is contraindicated for

-  Patients with bleeding disorders (**related to the potential for prolonged bleeding from the biopsy site**)

INDICATIONS

- Evidence of breast lesion by palpation, mammography, or ultrasound
- Identify patients with breast or other types of cancer that may respond to hormone or antihormone therapy
- Monitor responsiveness to hormone or antihormone therapy
- Observable breast changes such as “peau d’orange” skin, scaly skin of the areola, drainage from the nipple, or ulceration of the skin

POTENTIAL DIAGNOSIS

Positive findings in

- Carcinoma of the breast
- Hormonal therapy (ER and PR)
- Receptor-positive tumors (ER and PR)

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Antiestrogen preparations (e.g., tamoxifen) ingested 2 mo before tissue sampling will affect test results (ER and PR).
- Pretesting preservation of the tissue is method and test dependent. The testing laboratory should be consulted for proper instructions prior to the biopsy procedure.
- Failure to transport specimen to the laboratory immediately can result in degradation of tissue. Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results.

- Massive tumor necrosis or tumors with low cellular composition falsely decrease results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating breast health.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's reproductive system, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results. Ensure that the patient has not received antiestrogen therapy within 2 mo of the test.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; a general anesthesia will be administered prior to the open

biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by an HCP specializing in this procedure. The surgical procedure usually takes about 20 to 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**) or seeding of the biopsy tract with tumor cells.

- ▶ Ensure that the patient has complied with dietary restrictions. Ensure that the patient has not received antiestrogen therapy within 2 mo of the test.

- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location, especially right or left breast.
- ▶ Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, use antibiotics that are consistent with current guidelines specific to the procedure, and use clippers to remove hair from the surgical site if appropriate.
- ▶ After administration of general anesthesia and surgical preparation are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.

Needle Biopsy

- ▶ Direct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Instruct the patient to take a deep breath, exhale forcefully, and hold the breath while the biopsy needle is inserted and rotated to obtain a core of breast tissue. Once the needle is removed, the patient may breathe. Pressure is applied to the site for 3 to 5 min, then a sterile pressure dressing is applied.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the

biopsy site. Instruct the patient to immediately report chills or fever.

- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Society (www.cancer.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Decisions regarding the need for and frequency of breast self-examination, mammography, magnetic resonance imaging (MRI) breast, or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society (ACS) recommends breast examinations be performed every 3 years for women between the ages of 20 and 39 years and annually for women over 40 years of age; annual mammograms should be performed on women 40 years and older as long as they are in good health. The ACS also recommends annual MRI testing for women at high risk of developing breast cancer. Genetic testing for inherited mutations (BRCA1 and BRCA2) associated with increased risk of developing breast cancer may be ordered for women at risk. The test is performed on a blood specimen. The most current guidelines for breast cancer screening of the general population as well as of individuals with increased risk are available from the American Cancer

Society (www.cancer.org), the American College of Obstetricians and Gynecologists (ACOG) (www.acog.org), and the American College of Radiology (www.acr.org). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage the patient to review corresponding literature provided by a pharmacist.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include cancer antigens, ductography, mammogram, MRI breast, stereotactic biopsy breast, and US breast.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Biopsy, Cervical

SYNONYM/ACRONYM: Cone biopsy, LEEP.

COMMON USE: To assist in diagnosing and staging cervical cancer.

SPECIMEN: Cervical tissue.

NORMAL FINDINGS: (Method: Microscopic examination of tissue cells) No abnormal cells or tissue.

DESCRIPTION: Biopsy is the excision of a sample of tissue that can be analyzed microscopically to determine cell morphology and the presence of tissue abnormalities. The cervical biopsy is used to assist in confirmation of cancer when screening tests are positive. Cervical biopsy is obtained using an instrument that punches into the tissue and retrieves a tissue sample. Schiller's test entails applying an iodine solution to the cervix. Normal cells pick up the iodine and stain brown. Abnormal cells do not pick up any color.

Punch biopsy results may indicate the need for a cone biopsy of the cervix. Cone biopsy involves removing a wedge of tissue from the cervix by using a surgical knife, a carbon dioxide laser, or a loop electro-surgical excision procedure (LEEP). LEEP can be performed by placing the patient under a general anesthetic; by a regional anesthesia, such as a spinal or epidural; or by a cervical block whereby a local anesthetic is injected into the cervix. The patient is given oral or IV pain medicine in conjunction with the local anesthetic when this

method is used. Following colposcopy or cervical biopsy, LEEP can be used to treat abnormal tissue identified on biopsy.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*) or acute pelvic inflammatory disease

INDICATIONS

- Follow-up to abnormal Papanicolaou (Pap) smear, Schiller's test, or colposcopy
- Suspected cervical malignancy

POTENTIAL DIAGNOSIS

Positive findings in

- Carcinoma in situ
- Cervical dysplasia
- Cervical polyps

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report.

Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- This test should not be performed while the patient is menstruating.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of cervical disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergies, especially allergies or sensitivities to latex, iodine, or anesthetics.
- ▶ Obtain a history of the patient's reproductive system, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address

concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the percutaneous biopsy; general anesthesia will be administered prior to the open biopsy. Explain that no pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient the biopsy is performed under sterile conditions by an HCP specializing in this procedure. The biopsy can be performed in the HCP's office and takes approximately 5 to 10 min to complete. The open biopsy is performed in a surgical suite, usually takes about 20 to 30 min to complete, and sutures may be necessary to close the site.

▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

▶ Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**)

- ▶ Ensure that the patient has complied with dietary restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Have the patient remove clothes below the waist. Assist the patient into a lithotomy position on a gynecological examination table (with feet in stirrups). Drape the patient's legs. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local or general anesthetic and the procedure.

Punch Biopsy

- ▶ Iodine solution is used to cleanse the cervix and distinguish normal from abnormal tissue. Local anesthesia, analgesics, or both, are administered to minimize discomfort.
- ▶ A small, round punch is rotated into the skin to the desired depth. The cylinder of skin is pulled upward with forceps and separated at its base with a scalpel or scissors.

LEEP in the HCP's Office

- ▶ A speculum is inserted into the vagina and is opened to gently spread apart the vagina for inspection of the cervix.
- ▶ Iodine solution is used to cleanse the cervix and distinguish normal from abnormal tissue. Local anesthesia,

analgesics, or both, are administered to minimize discomfort.

- ▶ The diseased tissue is removed along with a small amount of healthy tissue along the margins of the biopsy to ensure that no diseased tissue is left in the cervix after the procedure.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, use antibiotics that are consistent with current guidelines specific to the procedure, and use clippers to remove hair from the surgical site if appropriate.
- ▶ After administration of general anesthesia and surgical preparation are completed, the procedure is carried out as noted above.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the surgical patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria,

tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

- ▶ Advise the patient to expect a gray-green vaginal discharge for several days, that some vaginal bleeding may occur for up to 1 wk but should not be heavier than a normal menses, and that some pelvic pain may occur. Instruct the patient to wear a sanitary pad, and advise the patient that tampons should not be used for 1 to 3 wk. Patients who have undergone a simple cervical punch biopsy can usually resume normal activities immediately following the procedure. Instruct patients who have undergone LEEP or open biopsy to avoid strenuous activity for 8 to 24 hr; to avoid douching or intercourse for 2 to 4 wk or as instructed; and to report excessive bleeding, chills, fever, or any other unusual findings to the HCP.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of conventional or liquid-based Pap tests or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society's guidelines for preventing cervical cancer recommend cytological screening every 3 years for women age 20 to 29 years; co-testing for HPV and cytological screening every 5 years (or cytological screening alone every 3 years for women age 30 to 65 years; no screening is recommended for

women who have had a hysterectomy). The most current guidelines for cervical cancer screening of the general population as well as of individuals with increased risk are available from the American Cancer Society (www.cancer.org) and the American College of Obstetricians and Gynecologists (ACOG) (www.acog.org). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage

her to review corresponding literature provided by a pharmacist.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include *Chlamydia* group antibodies, colposcopy, culture anal/genital, culture viral, Pap smear, and syphilis serology.
- ▶ See the Reproductive System table at the end of the book for related tests by body system.

Biopsy, Chorionic Villus

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing genetic fetal abnormalities such as Down syndrome.

SPECIMEN: Chorionic villus tissue.

NORMAL FINDINGS: (Method:Tissue culture) Normal karyotype.

DESCRIPTION: This test is used to detect fetal abnormalities caused by numerous genetic disorders. Examples of genetic defects that are commonly tested for and can be identified from a chorionic villus sampling include sickle cell anemia and cystic fibrosis. The advantage over amniocentesis is that it can be performed as early as the 8th week of pregnancy, permitting earlier decisions regarding termination of pregnancy. However, unlike amniocentesis, this test will not detect neural tube defects.

This procedure is contraindicated for

-  Patients with a history of or in the presence of incompetent cervix, vaginal infection, or Rh sensitization.

INDICATIONS

- Assist in the diagnosis of in utero metabolic disorders such as cystic fibrosis or other errors of lipid, carbohydrate, or amino acid metabolism
- Detect abnormalities in the fetus of women of advanced maternal age
- Determine fetal gender when the mother is a known carrier of

a sex-linked abnormal gene that could be transmitted to male offspring, such as hemophilia or Duchenne's muscular dystrophy

- Evaluate fetus in families with a history of genetic disorders, such as Down syndrome, Tay-Sachs disease, chromosome or enzyme anomalies, or inherited hemoglobinopathies

POTENTIAL DIAGNOSIS

Abnormal karyotype: *Numerous genetic disorders. Generally, the laboratory provides detailed interpretive information regarding the specific chromosome abnormality detected.*

CRITICAL FINDINGS

- Identification of abnormalities in chorionic villus tissue.

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Failure to follow dietary restrictions before the procedure may cause

the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of in utero genetic disorders.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Include any family history of genetic disorders such as cystic fibrosis, Duchenne's muscular dystrophy, hemophilia, sickle cell anemia, Tay-Sachs disease, thalassemia, and trisomy 21. Obtain maternal Rh type. If Rh-negative, check for prior sensitization.
- ▶ Record the date of the last menstrual period and determine that the pregnancy is in the first trimester between the 10th and 12th weeks.
- ▶ Obtain a history of intravenous drug use, high-risk sexual activity, or occupational exposure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Warn the patient that normal results do not guarantee a normal fetus. Assure the patient that precautions to avoid injury to the fetus will be taken by locating the fetus with ultrasound. Address concerns about pain related to the procedure. Explain that during the transabdominal procedure, any discomfort with a needle biopsy will be minimized with local anesthetics. Explain that during the transvaginal procedure, some cramping may be experienced as the catheter is guided through the cervix. Encourage relaxation and controlled breathing

during the procedure to aid in reducing any mild discomfort. Inform the patient that specimen collection is performed by an HCP specializing in this procedure and usually takes approximately 10 to 15 min to complete.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Instruct the patient to drink a glass of water about 30 min prior to testing so that the bladder is full. This elevates the uterus higher in the pelvis. The patient should not void before the procedure.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Women at risk for or with known cervical abnormalities should be aware of the risks of miscarriage due to incompetent (loose) cervix (**related to passing a catheter or other instrument through the cervix, weakening the cervix**). Rh-negative women risk mixing of the maternal and fetal blood supply (**related to the invasive nature of the procedure and potentially resulting in development of maternal antibodies directed against fetal blood cells; a situation that can develop into hemolytic disease of the newborn**).

- ▶ Ensure that the patient has a full bladder before the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.

- ▶ Have the patient remove clothes below the waist. **Transabdominal:** Assist the patient into a supine position on the examination table with abdomen exposed. Drape the patient's legs, leaving abdomen exposed. **Transvaginal:** Assist the patient into a lithotomy position on a gynecologic examination table (with feet in stirrups). Drape the patient's legs. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- ▶ Record maternal and fetal baseline vital signs, and continue to monitor throughout the procedure. Monitor for uterine contractions. Monitor fetal vital signs using ultrasound. Protocols may vary among facilities.
- ▶ After the administration of local anesthesia, use clippers to remove hair from the surgical site if appropriate, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Transabdominal Biopsy

- ▶ Assess the position of the amniotic fluid, fetus, and placenta using ultrasound.
- ▶ A needle is inserted through the abdomen into the uterus, avoiding contact with the fetus. A syringe is connected to the needle, and the specimen of chorionic villus cells is withdrawn from the uteroplacental area. Pressure is applied to the site for 3 to 5 min, and then a sterile pressure dressing is applied.

Transvaginal Biopsy

- ▶ Assess the position of the fetus and placenta using ultrasound.
- ▶ A speculum is inserted into the vagina and is opened to gently spread apart the vagina for inspection of the cervix. The cervix is cleansed with a swab of antiseptic solution.
- ▶ A catheter is inserted through the cervix into the uterus, avoiding contact with the fetus. A syringe is connected to the catheter, and the specimen of chorionic villus cells is withdrawn from the uteroplacental area.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., premature labor, allergic reaction, anaphylaxis).

- Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- After the procedure, the patient is placed in the left side-lying position, and both maternal and fetal vital signs are monitored for at least 30 min. Protocols may vary among facilities.
- Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- Instruct the patient in the care and assessment of the site.
- Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site.
- Advise the patient to expect mild cramping, leakage of small amount of amniotic fluid, and vaginal spotting for up to 2 days following the procedure. Instruct the patient to report moderate to severe abdominal pain or cramps, increased or prolonged leaking of amniotic fluid from vagina or abdominal needle site, vaginal bleeding that is heavier than spotting, and either chills or fever.
- Administer Rh₀(D) immune globulin (RhoGAM IM or Rhophylac IM or IV) to maternal Rh-negative patients to prevent maternal Rh sensitization should the fetus be Rh-positive.
- Administer mild analgesic and antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Encourage family to seek counseling if concerned with pregnancy termination or to seek genetic counseling if chromosomal abnormality is determined. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of delivering a developmentally challenged infant are discussed with options (termination of pregnancy or adoption). It is also important to discuss problems the mother and father may experience (guilt, depression, anger) if fetal abnormalities are detected.

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage her to review corresponding literature provided by a pharmacist.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. There are numerous tests for fetal genetic testing associated with inherited diseases and congenital abnormalities. The tests can be performed from chorionic villus sampling or amniotic fluid by methods that include polymerase chain reaction, microarray, and cell culture with karyotyping comparison. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include amniotic fluid analysis, and L/S ratio, chromosome analysis, α_1 fetoprotein, HCG, hexosaminidase A and B, newborn screening, US biophysical profile, and US obstetric.
- Refer to the Reproductive System table at the end of the book for related tests by body system.

Biopsy, Intestinal

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in confirming a diagnosis of intestinal cancer or disease.

SPECIMEN: Intestinal tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue) No abnormal tissue or cells.

DESCRIPTION: Intestinal biopsy is the excision of a tissue sample from the small intestine for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test assists in confirming the diagnosis of cancer or intestinal disorders. Biopsy specimen is usually obtained during endoscopic examination.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*) or aortic arch aneurysm.

INDICATIONS

- Assist in the diagnosis of various intestinal disorders, such as lactose and other enzyme deficiencies, celiac disease, and parasitic infections
- Confirm suspected intestinal malignancy
- Confirm suspicious findings during endoscopic visualization of the intestinal wall

POTENTIAL DIAGNOSIS

Abnormal findings in

- Cancer
- Celiac disease
- Lactose deficiency
- Parasitic infestation
- Tropical sprue

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Barium swallow within 48 hr of small intestine biopsy affects results.

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of intestinal disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's gastrointestinal and immune systems, any bleeding disorders, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that a sedative may be administered to promote relaxation during the procedure. Inform the patient that the procedure is performed by an HCP specializing in this procedure and usually takes about 60 min to complete.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, anesthetics, and analgesics.
- ▶ Explain that a clear liquid diet is to be consumed 1 day prior to the procedure. Instruct the patient that to reduce the risk

of nausea and vomiting, clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ Provide the patient with a gown, robe, and foot coverings and instruct him or her to void prior to the procedure.
- ▶ Instruct the patient to remove dentures. Inform the HCP if the patient has any crowns or caps on the teeth.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**) or seeding of the biopsy tract with tumor cells
- ▶ Ensure that the patient has complied with dietary restrictions.
 - ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Have emergency equipment readily available.
 - ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
 - ▶ Assist the patient into a semireclining position. Instruct the patient to cooperate fully and to follow directions. Direct

the patient to breathe normally and to avoid unnecessary movement.

- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.

Esophagogastroduodenoscopy (EGD) Biopsy

- ▶ A local anesthetic is sprayed into the throat. A protective tooth guard and a bite block may be placed in the mouth.
- ▶ The flexible endoscope is passed into and through the mouth, and the patient is asked to swallow. Once the endoscope passes into the esophagus, assist the patient into the left lateral position. A suction device is used to drain saliva.
- ▶ The esophagus, stomach, and duodenum are visually examined as the endoscope passes through each section. A biopsy specimen can be taken from any suspicious sites.
- ▶ Tissue samples are obtained by inserting a cytology brush or biopsy forceps through the endoscope.
- ▶ When the examination and tissue removal are complete, the endoscope and suction device are withdrawn and the tooth guard and bite block are removed.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to report any chest pain, upper abdominal pain, pain on swallowing, difficulty breathing, or expectoration of blood. Report these to the HCP immediately.
- ▶ Administer mild analgesic and antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include albumin, antibodies gliadin, calcium, cancer antigens, capsule endoscopy, colonoscopy, D-xylose tolerance, fecal analysis, fecal fat, folic acid, iron/TIBC, LTT, ova and parasite, potassium, PT/INR, sodium, US abdomen, vitamin B₁₂, and vitamin D.
- ▶ Refer to the Gastrointestinal and Immune systems tables at the end of the book for related tests by body system.

Biopsy, Kidney

SYNONYM/ACRONYM: Renal biopsy.

COMMON USE: To assist in diagnosing cancer and other renal disorders.

SPECIMEN: Kidney tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue) No abnormal cells or tissue.

DESCRIPTION: Kidney or renal biopsy is the excision of a tissue sample from the kidney for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test assists in confirming a diagnosis of cancer found on x-ray or ultrasound or to diagnose certain inflammatory or immunological conditions. Biopsy specimen is usually obtained either percutaneously or after surgical incision.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*), advanced renal disease, uncontrolled hypertension, or solitary kidney (*except transplanted kidney as the biopsy may be required to determine whether rejection or other damage is occurring*).

INDICATIONS

- Assist in confirming suspected renal malignancy
- Assist in the diagnosis of the cause of renal disease
- Determine extent of involvement in systemic lupus erythematosus or other immunological disorders

- Monitor progression of nephrotic syndrome
- Monitor renal function after transplantation

POTENTIAL DIAGNOSIS

Positive findings in

- Acute and chronic poststreptococcal glomerulonephritis
- Amyloidosis infiltration
- Cancer
- Disseminated lupus erythematosus
- Goodpasture's syndrome
- Immunological rejection of transplanted kidney
- Nephrotic syndrome
- Pyelonephritis
- Renal venous thrombosis

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify

accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Obesity and severe spinal deformity can make percutaneous biopsy impossible.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of kidney disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's genitourinary and immune systems, especially any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin

and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered before the percutaneous biopsy to promote relaxation and reduce discomfort; general anesthesia will be administered before the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by an HCP specializing in this procedure. The surgical procedure usually takes about 60 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 40 min to complete.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, analgesics, or IV sedation.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Bleeding (*related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners*) or seeding of the biopsy tract with tumor cells

- ▶ Ensure that the patient has complied with dietary restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location, especially right or left kidney.
- ▶ Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. Direct the patient to avoid unnecessary movement.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ After the administration of general or local anesthesia, use clippers to remove hair from the surgical site if appropriate, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, and use antibiotics that are consistent with current guidelines specific to the procedure.
- ▶ After administration of general anesthesia and surgical preparation are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

Needle Biopsy

- ▶ A sandbag may be placed under the abdomen to aid in moving the kidneys to the desired position. Direct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Instruct the patient to take a deep breath, exhale forcefully, and hold the breath while the biopsy needle is inserted and rotated to obtain a core of renal tissue. Once the needle is removed, the patient may breathe. Pressure is applied to the site for 5 to 20 min, then a sterile pressure dressing is applied.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor

intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.

- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Inform the patient that blood may be seen in the urine after the first or second postprocedural voiding.
- ▶ Monitor fluid intake and output for 24 hr. Instruct the patient on intake and output recording and provide appropriate measuring containers.
- ▶ Instruct the patient to report any changes in urinary pattern or volume or any unusual appearance of the urine. If urinary volume is less than 200 mL in the first 8 hr, encourage the patient to increase fluid intake unless contraindicated by another medical condition.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire

course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include albumin, aldosterone, angiography renal, antibodies antiglomerular basement membrane, β_2 -microglobulin, BUN, CT renal, creatinine, creatinine clearance, cytology urine, cystoscopy, IVP, KUB studies, osmolality, PTH, potassium, protein, renin, renogram, sodium, US kidney, and UA.
- ▶ Refer to the Genitourinary and Immune systems tables at the end of the book for related tests by body system.

Biopsy, Liver

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing liver cancer, and other liver disorders such as cirrhosis and hepatitis.

SPECIMEN: Liver tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue) No abnormal cells or tissue.

DESCRIPTION: Liver biopsy is the excision of a tissue sample from the liver for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test is used to assist in confirming a diagnosis of cancer or certain disorders of the hepatic parenchyma. Biopsy specimen is usually obtained either percutaneously or after surgical incision.

- Cholesterol ester storage disease
- Cirrhosis
- Galactosemia
- Hemochromatosis
- Hepatic involvement with systemic lupus erythematosus, sarcoidosis, or amyloidosis
- Hepatitis
- Parasitic infestations (e.g., amebiasis, malaria, visceral larva migrans)
- Reye's syndrome
- Wilson's disease

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*), suspected vascular tumor of the liver, ascites that may obscure proper insertion site for needle biopsy, subdiaphragmatic or right hemothoracic infection, or biliary tract infection.

INDICATIONS

- Assist in confirming suspected hepatic malignancy
- Assist in confirming suspected hepatic parenchymal disease
- Assist in diagnosing the cause of persistently elevated liver enzymes, hepatomegaly, or jaundice

POTENTIAL DIAGNOSIS

Positive findings in

- Benign tumor
- Cancer

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the

report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of liver disease.
- ▶ Obtain a history of the patient's complaints, especially fatigue and pain related to inflammation and swelling of the liver. Include a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's hepatobiliary and immune systems, especially any bleeding disorders and other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be

necessary to remove hair from the site before the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered before the percutaneous biopsy to promote relaxation and reduce discomfort; general anesthesia will be administered before the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by an HCP specializing in this procedure. The surgical procedure usually takes about 90 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, analgesics, or IV sedation.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Bleeding (**related to a bleeding disorder, bleeding initiated by surgical**

invasion of a vascular tumor of the liver, or the effects of natural products and medications known to act as blood thinners) or seeding of the biopsy tract with tumor cells

- ▶ Ensure that the patient has complied with dietary restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Assist the patient to the desired position depending on the test site to be used and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure. Instruct the patient to avoid coughing or straining, which may increase intra-abdominal pressure.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ After the administration of general or local anesthesia, use clippers to remove hair from the surgical site if appropriate, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures.

Administer ordered prophylactic antibiotics 1 hr before incision, and use antibiotics that are consistent with current guidelines specific to the procedure.

- ▶ After administration of general anesthesia and surgical preparation are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

Needle Biopsy

- ▶ Direct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Instruct the patient to take a deep breath, exhale forcefully, and hold the breath while the biopsy needle is inserted and rotated to obtain a core of liver tissue. Once the needle is removed, the patient may breathe. Pressure is applied to the site for 3 to 5 min, then a sterile pressure dressing is applied.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria,

tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site. Instruct the patient to immediately report chills or fever.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing,

treatment, or referral to another HCP.

- ▶ Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, albumin, ALP, ammonia, amylase, AMA/ASMA, α_1 -antitrypsin/phenotyping, AST, bilirubin, cholesterol, coagulation factors, CBC, copper, GGT, hepatitis antigens and antibodies, infectious mononucleosis screen, laparoscopy abdominal, lipase, liver and spleen scan, MRI liver, PT/INR, radiofrequency ablation liver, UA, US abdomen, and US liver.
- ▶ Refer to the Hepatobiliary and Immune systems tables at the end of the book for related tests by body system.

Biopsy, Lung

SYNONYM/ACRONYM: Transbronchial lung biopsy, open lung biopsy.

COMMON USE: To assist in diagnosing lung cancer and other lung tissue disease.

SPECIMEN: Lung tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue) No abnormal tissue or cells; no growth in culture.

DESCRIPTION: A biopsy of the lung is performed to obtain lung tissue for examination of pathological features. The specimen can be obtained transbronchially or by open lung biopsy. In a transbronchial biopsy, forceps pass through the bronchoscope to obtain the specimen. In a transbronchial needle aspiration biopsy, a needle passes through a bronchoscope to obtain the specimen. In a trans-catheter bronchial brushing, a brush is inserted through the bronchoscope. In an open lung biopsy, the chest is opened and a small thoracic incision is made to remove tissue from the chest wall. Lung biopsies are used to differentiate between infection and other sources of disease indicated by initial radiology studies, computed tomography scans, or sputum analysis. Specimens are cultured to detect pathogenic organisms or directly examined for the presence of malignant cells.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*)

INDICATIONS

- Assist in the diagnosis of lung cancer
- Assist in the diagnosis of fibrosis and degenerative or inflammatory diseases of the lung
- Assist in the diagnosis of sarcoidosis

POTENTIAL DIAGNOSIS

Abnormal findings in

- Amyloidosis
- Cancer
- Granulomas
- Infections caused by *Blastomyces*, *Histoplasma*, *Legionella* spp.,

and *Pneumocystis jiroveci* (formerly *P. carinii*)

- Sarcoidosis
- Systemic lupus erythematosus
- Tuberculosis

CRITICAL FINDINGS 

- Any postprocedural decrease in breath sounds noted at the biopsy site should be reported immediately.
- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy
- Shortness of breath, cyanosis, or rapid pulse during the procedure must be reported immediately

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Conditions such as vascular anomalies of the lung, bleeding abnormalities, or pulmonary

hypertension may increase the risk of bleeding.

- Conditions such as bullae or cysts and respiratory insufficiency increase the risk of pneumothorax.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of lung disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's immune and respiratory systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered before the percutaneous biopsy to promote relaxation and reduce discomfort; general anesthesia will be administered before the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Atropine is usually given before bronchoscopy examinations to reduce bronchial secretions and prevent vagally induced bradycardia. Meperidine (Demerol) or morphine may be given as a sedative. Lidocaine is sprayed in the patient's throat to reduce discomfort caused by the presence of the tube. Inform the patient that the biopsy is performed under sterile conditions by an HCP specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 to 30 min to complete.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ Have the patient void before the procedure.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Potential Complications:

Bleeding (*related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners*), pneumothorax (*increased risk for pneumothorax is related to the presence of bullae or cysts and respiratory insufficiency*),

hemoptysis, air embolism, or seeding of the biopsy tract with tumor cells

- ▶ Ensure that the patient has complied with dietary restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available. Keep resuscitation equipment on hand in the case of respiratory impairment or laryngospasm after the procedure.
- ▶ Avoid using morphine sulfate in those with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location, especially right or left lung.
- ▶ Have patient remove dentures and notify the HCP if the patient has permanent crowns on teeth. Have the patient remove clothing and change into a gown for the procedure.

Assist the patient to a comfortable position and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.

- ▶ Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ After the administration of general or local anesthesia, use clippers to remove hair from the surgical site if appropriate, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, and use antibiotics that are consistent with current guidelines specific to the procedure.
- ▶ The patient is prepared for thoracotomy under general anesthesia in the operating room. Tissue specimens are collected from suspicious sites. Place specimen from needle aspiration or brushing on clean glass microscope slides. Place tissue or aspirate specimens in appropriate sterile container for culture or appropriate fixative container for histological studies.
- ▶ Carefully observe/assess the patient for any signs of respiratory distress during the procedure.
- ▶ A chest tube is inserted after the procedure.

Needle Biopsy

- ▶ Instruct the patient to take slow, deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Assist patient to a sitting position with arms on a pillow over a bed table. Instruct patient to avoid coughing during the procedure. The needle is inserted through the posterior chest wall and into the intercostal space. The needle is rotated to obtain the sample and then withdrawn.

Pressure is applied to the site with a petroleum jelly gauze, and a pressure dressing is applied over the petroleum jelly gauze.

Bronchoscopy

- ▶ Provide mouth care to reduce oral bacterial flora.
- ▶ After administration of general anesthesia, position the patient in a supine position with the neck hyperextended. If local anesthesia is used, the patient is seated while the tongue and oropharynx are sprayed and swabbed with anesthetic. Provide an emesis basin for the increased saliva and encourage the patient to spit out the saliva because the gag reflex may be impaired. When loss of sensation is adequate, the patient is placed in a supine or side-lying position. The fiberoptic scope can be introduced through the nose, the mouth, an endotracheal tube, a tracheostomy tube, or a rigid bronchoscope. Most common insertion is through the nose. Patients with copious secretions or massive hemoptysis, or in whom airway complications are more likely, may be intubated before the bronchoscopy. Additional local anesthetic is applied through the scope as it approaches the vocal cords and the carina, eliminating reflexes in these sensitive areas. The fiberoptic approach allows visualization of airway segments without having to move the patient's head through various positions.
- ▶ After visual inspection of the lungs, tissue samples are collected from suspicious sites by bronchial brush or biopsy forceps to be used for cytological and microbiological studies.
- ▶ After the procedure, the bronchoscope is removed. Patients who had local anesthesia are placed in a semi-Fowler's position to recover.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in properly labeled specimen containers containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Emergency resuscitation equipment should be readily available if the vocal cords become spastic after intubation.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the biopsy site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site.
- ▶ Observe/assess the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breath sounds over the affected area. Monitor chest tube patency and drainage after a thoracotomy.
- ▶ Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.

- ▶ Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.
- ▶ Observe/assess the patient's sputum for blood if a biopsy was taken, because large amounts of blood may indicate the development of a problem; a small amount of streaking is expected. Evaluate the patient for signs of bleeding, such as tachycardia, hypotension, or restlessness.
- ▶ Instruct the patient to remain in a semi-Fowler's position after bronchoscopy or fine-needle aspiration to maximize ventilation. Semi-Fowler's position is a semisitting position with the knees flexed and supported by pillows on the bed or examination table. Instruct the patient to stay in bed lying on the affected side for at least 2 hr with a pillow or rolled towel under the site to prevent bleeding. The patient will also need to remain on bedrest for 24 hr.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient to use lozenges or gargle for throat discomfort. Inform the patient of smoking cessation programs

as appropriate. Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons, including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C are also important to prevent pulmonary infection and to decrease the extent of lung tissue damage. The importance of following the prescribed diet should be stressed to the patient/caregiver. Educate the patient regarding access to counseling services, as appropriate. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include arterial/alveolar oxygen ratio, antibodies antiglomerular basement membrane, blood gases, bronchoscopy, chest x-ray, CBC, CT thoracic, culture sputum, cytology sputum, gallium scan, gram/acid fast stain, lung perfusion scan, lung ventilation scan, MRI chest, mediastinoscopy, pleural fluid analysis, PFT, and TB skin tests.
- ▶ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Biopsy, Lymph Node

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing cancer such as lymphoma and leukemia as well as other systemic disorders.

SPECIMEN: Lymph node tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue) No abnormal tissue or cells.

DESCRIPTION: Lymph node biopsy is the excision of a tissue sample from one or more lymph nodes for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test assists in confirming a diagnosis of cancer, diagnosing disorders causing systemic illness, or determining the stage of metastatic cancer. A biopsy specimen is usually obtained either by needle biopsy or after surgical incision. Biopsies are most commonly performed on the following types of lymph nodes: cervical nodes, which drain the face and scalp; axillary nodes, which drain the arms, breasts, and upper chest; and inguinal nodes, which drain the legs, external genitalia, and lower abdominal wall.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*)

INDICATIONS

- Assist in confirming suspected fungal or parasitic infections of the lymphatics
- Assist in confirming suspected malignant involvement of the lymphatics

- Determine the stage of metastatic cancer
- Differentiate between benign and malignant disorders that may cause lymph node enlargement
- Evaluate persistent enlargement of one or more lymph nodes for unknown reasons

POTENTIAL DIAGNOSIS

Abnormal findings in

- Chancroid
- Fungal infection (e.g., cat scratch disease)
- Immunodeficiency
- Infectious mononucleosis
- Lymph involvement of systemic diseases (e.g., systemic lupus erythematosus, sarcoidosis)
- Lymphangitis
- Lymphogranuloma venereum
- Malignancy (e.g., lymphomas, leukemias)
- Metastatic disease
- Parasitic infestation (e.g., pneumoconiosis)

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP).

A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of lymph node disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's immune system, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility

of pregnancy in perimenopausal women.

- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered before the percutaneous biopsy to promote relaxation and reduce discomfort; general anesthesia will be administered before the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by an HCP, with support staff, specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, analgesics, or IV sedation.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More

information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Bleeding (*related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners*) or seeding of the biopsy tract with tumor cells

- ▶ Ensure that the patient has complied with dietary restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the

patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.

- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ After the administration of general or local anesthesia, use clippers to remove hair from the surgical site if appropriate, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, and use antibiotics that are consistent with current guidelines specific to the procedure.
- ▶ After administration of general anesthesia and surgical preparation are completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

Needle Biopsy

- ▶ Instruct the patient to take slow, deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. The node is grasped with sterile gloved fingers, and a needle (with attached syringe) is inserted directly into the node. The node is aspirated to collect the specimen. Pressure is applied to the site for 3 to 5 min, then a sterile dressing is applied.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in formalin solution. Label the specimen, indicating site location, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, CD4/CD8 enumeration, cerebrospinal fluid analysis, *Chlamydia* serology, CBC, CT pelvis, CT thoracic, culture for bacteria/fungus, CMV, Gram stain, HIV-1/HIV-2 serology, immunofixation electrophoresis, immunoglobulins (A, G, and M), infectious mononucleosis screen, lymphangiography, mammogram, mediastinoscopy, PET pelvis, RF, total protein and fractions, toxoplasmosis serology, and US lymph nodes.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Biopsy, Muscle

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing muscular disease such as Duchenne's muscular dystrophy as well as other neuropathies and parasitic infections.

SPECIMEN: Muscle tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue) No abnormal tissue or cells.

DESCRIPTION: Muscle biopsy is the excision of a muscle tissue sample for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test is used to confirm a diagnosis of neuropathy or myopathy and to diagnose parasitic infestation. A biopsy specimen is usually obtained from the deltoid or gastrocnemius muscle after a surgical incision.

- Fungal infection
- Myasthenia gravis
- Myotonia congenita
- Parasitic infestation
- Polymyalgia rheumatica
- Polymyositis

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*)

INDICATIONS

- Assist in confirming suspected fungal infection or parasitic infestation of the muscle
- Assist in diagnosing the cause of neuropathy or myopathy
- Assist in the diagnosis of Duchenne's muscular dystrophy

POTENTIAL DIAGNOSIS

Abnormal findings in

- Alcoholic myopathy
- Amyotrophic lateral sclerosis
- Duchenne's muscular dystrophy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and

any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- If electromyography is performed before muscle biopsy, residual inflammation may lead to false-positive biopsy results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of musculoskeletal disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's immune and musculoskeletal systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address

concerns about pain and explain that a sedative and/or analgesia will be administered before the percutaneous biopsy to promote relaxation and reduce discomfort; general anesthesia will be administered before the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by an HCP specializing in this procedure. The surgical procedure usually takes about 20 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids, antibiotics, anesthetics, or sedatives.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**)
- ▶ Ensure that the patient has complied with dietary restrictions.

- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Assist the patient to a comfortable position: a supine position (for deltoid biopsy) or prone position (for gastrocnemius biopsy). Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ After the administration of general or local anesthesia, use clippers to remove hair from the surgical site if appropriate, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, and use antibiotics that are consistent with current guidelines specific to the procedure.
- ▶ After administration of general anesthesia and surgical preparation are completed, an incision is made, suspicious areas are located, and tissue samples are collected.

Needle Biopsy

- ▶ Instruct the patient to take slow deep breaths when the local anesthetic is injected. Protect the site with sterile drapes.

- ▶ After infiltration of the site with local anesthetic, a cutting biopsy needle is introduced through a small skin incision and bored into the muscle. A core needle is introduced through the cutting needle, and a plug of muscle is removed. The needles are withdrawn, and the specimen is placed in a preservative solution. Pressure is applied to the site for 3 to 5 min, and then a pressure dressing is applied.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpernea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic

therapy, even if signs and symptoms disappear before completion of therapy.

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the

patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include AChR, aldolase, ANA, antibody Jo-1, antithyroglobulin antibodies, CK and isoenzymes, EMG, ENG, myoglobin, and RF.
- ▶ Refer to the Immune and Musculoskeletal systems tables at the end of the book for related tests by body system.

Biopsy, Prostate

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing prostate cancer.

SPECIMEN: Prostate tissue.

NORMAL FINDINGS: (Method: Microscopic examination of tissue cells) No abnormal cells or tissue.

DESCRIPTION: Biopsy of the prostate gland is performed to identify cancerous cells, especially if serum prostate-specific antigen (PSA) is increased. New technology makes it possible to combine data such as analysis of molecular biomarkers and cellular structure specific to the individual's biopsy tissue, standard tissue biopsy results, Gleason's score, number of positive tumor cores, tumor stage, presurgical and postsurgical PSA levels, and postsurgical margin status with computerized mathematical programs

to create a personalized report that predicts the likelihood of post-prostatectomy disease progression. Serial measurements of PSA in the blood are often performed before and after surgery. Approximately 15% to 40% of patients who have had their prostate removed will encounter an increase in PSA. Patients treated for prostate cancer and who have had a PSA recurrence can still develop a metastasis as much as 8 yr after the postsurgical PSA level increased. The majority of tumors develop slowly and

require minimal intervention, but patients with an increase in PSA greater than 2.0 ng/mL in a year are more likely to have an aggressive form of prostate cancer with a greater risk of death. The Prostate Health Index (PHI) is another multi-marker strategy used to improve the positive prediction rate of prostate cancer, especially when PSA levels are considered to be moderately increased (between 4–10 ng/mL). The PHI applies information provided by the results of prostate marker blood tests to a mathematical formula and offers additional information for clinical decision making. The three tests used in the formula are the total PSA, free PSA, and p2PSA (an isoform of PSA, where: $PHI = p2PSA / [free\ PSA \times total\ PSA]$). Personalized medicine provides a technology to predict the progression of prostate cancer, likelihood of recurrence, or development of related metastatic disease. New technology makes it possible to

combine data such as analysis of molecular biomarkers and cellular structure specific to the individual's biopsy tissue, standard tissue biopsy results, Gleason score, number of positive tumor cores, tumor stage, presurgical and postsurgical PSA levels, and postsurgical margin status with computerized mathematical programs to create a personalized report that predicts the likelihood of post-prostatectomy disease progression.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*)

INDICATIONS

- Evaluate prostatic hypertrophy of unknown etiology
- Investigate suspected cancer of the prostate

POTENTIAL DIAGNOSIS

Positive findings in prostate cancer

Gleason Grading

- 1 Simple round glands, closely packed rounded masses with well-defined edges. Closely resemble normal prostate tissue.
- 2 Simple round glands, loosely packed in vague, rounded masses with loosely packed edges. Closely resemble normal prostate tissue.
- 3 Discrete glands of varying size and shape interposed among nonneoplastic cells.
- 4 Small, medium, or large ill-defined glands fused into cords, chains, or ragged infiltrating masses; glands may be perforated or have a hypernephromatoid pattern.
- 5 No glandular differentiation, solid sheets, cords, single cells with central necrosis.

Gleason's score is the sum of two grades assigned by the pathologist during microscopic examination of the biopsy samples. The score ranges from 1 to 10 with 10 being the worst. The first number assigned is the primary grade (1 to 5), which indicates

where the cancer is the most prominent. The second number is the secondary grade (1 to 5), which indicates where the cancer is next most prominent. It is important to have the breakdown in grading as well as the total score. For example, Patient A's

Gleason's score is $4 + 3 = 7$, and Patient B's Gleason's score is $3 + 4 = 7$. Even though both patients have the

same Gleason's score, Patient B has a slightly better prognosis because the primary area is graded a 3.

TNM Classification of Tumors

T refers to the size of the primary tumor

T_0 No evidence of primary tumor

T_{IS} Carcinoma in situ

T_{1-4} Increasing degrees in tumor size and involvement

N refers to lymph node involvement

N_0 No evidence of disease in lymph nodes

N_{1-4} Increasing degrees in lymph node involvement

N_x Regional lymph nodes unable to be assessed clinically

M refers to distant metastases

M_0 No evidence of distant metastases

M_{1-4} Increasing degrees of distant metastatic involvement, including distant nodes

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical

finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- The various sampling approaches have individual drawbacks that should be considered: Transurethral sampling does not always ensure that malignant cells will be included in the specimen, whereas transrectal sampling carries the risk of perforating the rectum and creating a channel through which malignant cells can seed normal tissue.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of prostate disease.
- ▶ Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies or sensitivities to latex or anesthetics.

- ▶ Obtain a history of the patient's genitourinary system, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort before the percutaneous biopsy; general anesthesia will be administered before the open biopsy. Explain to the patient that no pain will be experienced during the test when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by an HCP, with support staff, specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 20 min to complete. Instructions regarding the appropriate transport container for molecular diagnostic studies should be obtained from the laboratory prior to the procedure.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food

and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**) or seeding of the biopsy tract with tumor cells
- ▶ Ensure that the patient has complied with dietary restrictions.
 - ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days before the procedure. The number of days to withhold medication depends on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Have emergency equipment readily available.
 - ▶ Have the patient void before the procedure. Administer enemas if ordered.
 - ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
 - ▶ Assist the patient to a comfortable position, and direct the patient to

breathe normally during the beginning of the general anesthesia.

- ▶ Cleanse the biopsy site with an antiseptic solution, use clippers to remove hair from the surgical site if appropriate, and drape the area with sterile towels.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.

Transurethral Approach

- ▶ After administration of general anesthesia, position the patient on a urological examination table with the feet in stirrups. The endoscope is inserted into the urethra. The tissue is excised with a cutting loop and is placed in formalin solution.

Transrectal Approach

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, and use antibiotics that are consistent with current guidelines specific to the procedure.
- ▶ After administration of general anesthesia, position the patient in the Sims' position (left lateral). A rectal examination is performed to locate suspicious nodules. A biopsy needle guide is placed at the biopsy site, and the biopsy needle is inserted through the needle guide. The cells are aspirated, the needle is withdrawn, and the sample is placed in formalin solution.

Perineal Approach

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, and use antibiotics that are consistent with current guidelines specific to the procedure.
- ▶ After administration of general anesthesia, position the patient in the lithotomy position. Clean the perineum with an antiseptic solution, and protect the biopsy site with sterile drapes. A small incision is made, and the sample is removed by needle biopsy or biopsy punch and placed in formalin solution.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).

- ▶ Apply digital pressure to the biopsy site. If there is no bleeding after the perineal approach, place a sterile dressing on the biopsy site. Immediately notify the HCP if there is significant bleeding.
- ▶ Place tissue samples for standard biopsy examination in properly labeled specimen containers containing formalin solution, place tissue samples for molecular diagnostic studies in properly labeled specimen containers, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ **Nutritional Considerations:** There is growing evidence that inflammation and oxidation play key roles in the development of numerous diseases, including prostate cancer. Research also shows that diets containing dried beans, fresh fruits and vegetables, nuts, spices, whole grains, and smaller amounts of red meats can increase the amount of protective antioxidants. Regular exercise, especially in combination with a healthy diet, can bring about changes in the body's metabolism that decrease inflammation and oxidation.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Instruct the patient on intake and output recording and provide appropriate measuring containers.

- ▶ Encourage fluid intake of 3,000 mL unless contraindicated.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any chills, fever, redness, edema, bleeding, or pain at the biopsy site.
- ▶ Assess for infection, hemorrhage, or perforation of the urethra or rectum.
- ▶ Inform the patient that blood may be seen in the urine after the first or second postprocedural voiding.
- ▶ Instruct the patient to report any further changes in urinary pattern, volume, or appearance.
- ▶ Assess for nausea, pain, and bladder spasms. Administer antiemetic, analgesic, and antispasmodic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Cancer Institute (www.cancer.gov).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of routine PSA testing or other cancer screening procedures should be made after consultation between the patient and HCP. Recommendations made by various medical associations and national health organizations

regarding prostate cancer screening are moving away from routine PSA screening and toward informed decision making. The American Cancer Society's guidelines recommend that discussions about screening should begin at age 50 years for men at average risk, 45 years for men at high risk, and 40 years for men at the highest risk of developing prostate cancer. The most current guidelines for prostate cancer screening of the general population as well as of individuals with increased risk are available from the American Cancer Society (www.cancer.org) and the American Urological Association (www.aua.org). Counsel the patient, as appropriate, that sexual dysfunction related to altered body function, drugs, or radiation may occur. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include cystoscopy, cystourethrography voiding, PAP, PSA, retrograde ureteropyelography, semen analysis, and US prostate.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Biopsy, Skin

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing skin cancer.

SPECIMEN: Skin tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue)
No abnormal tissue or cells.

DESCRIPTION: Skin biopsy is the excision of a tissue sample from suspicious skin lesions. The microscopic analysis can determine cell morphology and the presence of tissue abnormalities. This test assists in confirming the diagnosis of malignant or benign skin lesions. A skin biopsy can be obtained by any of these four methods: curettage, shaving, excision, or punch. A Tzanck smear may be prepared from vesicles (blisters) present on the skin. Skin cells in the vesicles can be evaluated microscopically to indicate the presence of certain viruses, especially herpes, that cause cells to become enlarged and otherwise abnormal in appearance.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*)

INDICATIONS

- Assist in the diagnosis of keratoses, warts, moles, keloids, fibromas, cysts, or inflamed lesions
- Assist in the diagnosis of inflammatory process of the skin, especially herpes infection

- Assist in the diagnosis of skin cancer
- Evaluate suspicious skin lesions

POTENTIAL DIAGNOSIS

Abnormal findings in

- Basal cell carcinoma
- Cysts
- Dermatitis
- Dermatofibroma
- Keloids
- Malignant melanoma
- Neurofibroma
- Pemphigus
- Pigmented nevi
- Seborrheic keratosis
- Skin involvement in systemic lupus erythematosus, discoid lupus erythematosus, and scleroderma
- Squamous cell carcinoma
- Viral infection (herpes, varicella)
- Warts

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse.

The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of skin disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's immune and musculoskeletal systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including anticoagulants,

aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct that prophylactic antibiotics may be administered before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered before the punch biopsy to promote relaxation and reduce discomfort. Explain that any discomfort will be minimized with local anesthetics and systemic analgesics. Inform the patient the biopsy is performed under sterile conditions by an HCP, with support staff, specializing in this procedure. The procedure usually takes about 20 min to complete, and sutures may be necessary to close the site.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids, anesthetics, or sedatives, depending on the type of biopsy.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**) or seeding of the biopsy tract with tumor cells
- ▶ Ensure that the patient has complied with dietary restrictions if ordered by the HCP.
 - ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to

withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the local anesthetic and the procedure. Instruct the patient to cooperate fully, follow directions, and avoid unnecessary movement.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ After the administration of local anesthesia, use clippers to remove hair from the site if appropriate, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Curettage

- ▶ The skin is scraped with a curette to obtain specimen.

Shaving or Excision

- ▶ A scalpel is used to remove a portion of the lesion that protrudes above the epidermis. If the lesion is to be excised, the incision is made as wide and as deep as needed to ensure that the entire lesion is removed. Bleeding is controlled with external pressure to the site. Large wounds are closed with sutures. An adhesive bandage is applied when excision is complete.

Punch Biopsy

- ▶ A small, round punch about 4 to 6 mm in diameter is rotated into the skin to the desired depth. The cylinder of skin is pulled upward with forceps and separated at its base with a scalpel or scissors. If needed, sutures are

applied. A sterile dressing is applied over the site.

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the American Cancer Society (www.cancer.org). Educate the patient regarding access to counseling services.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for the removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. DNA testing for mutations

in the CDKN2A, CDK4, or BRAF V600 genes may be requested to identify those at high risk for developing cutaneous melanoma. The test for TA90 (melanoma-associated antigen) is used to evaluate the status of postoperative patients who have had localized areas of melanoma removed. Methods for these genetic markers include microarray, reverse transcriptase polymerase chain reaction (RT-PCR), and enzyme-linked immunosorbent assay (ELISA). Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include allergen-specific IgE, ANA, culture skin, eosinophil count, ESR, and IgE.
- ▶ Refer to the Immune and Musculoskeletal systems tables at the end of the book for related tests by body system.

Biopsy, Thyroid

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing thyroid cancer.

SPECIMEN: Thyroid gland tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue) No abnormal tissue or cells.

DESCRIPTION: Thyroid biopsy is the excision of a tissue sample for microscopic analysis to determine cell morphology and the presence of tissue abnormalities. This test assists in confirming a diagnosis of cancer or determining the cause of persistent thyroid symptoms. A biopsy specimen can be obtained by needle aspiration or by surgical excision.

This procedure is contraindicated for

-  Patients with bleeding disorders (*related to the potential for prolonged bleeding from the biopsy site*)

INDICATIONS

- Assist in the diagnosis of thyroid cancer or benign cysts or tumors

- Determine the cause of inflammatory thyroid disease
- Determine the cause of hyperthyroidism
- Evaluate enlargement of the thyroid gland

POTENTIAL DIAGNOSIS

Positive findings in

- Benign thyroid cyst
- Granulomatous thyroiditis
- Hashimoto's thyroiditis
- Nontoxic nodular goiter
- Thyroid cancer

CRITICAL FINDINGS

- Assessment of clear margins after tissue excision
- Classification or grading of tumor
- Identification of malignancy

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of thyroid disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's endocrine and immune systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Instruct the patient that prophylactic antibiotics may be administered before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered before the percutaneous biopsy to promote relaxation and reduce discomfort; general anesthesia will be administered before the open biopsy. Explain to the patient that no pain will be experienced during the test

when general anesthesia is used but that any discomfort with a needle biopsy will be minimized with local anesthetics and systemic analgesics. Inform the patient that the biopsy is performed under sterile conditions by an HCP, with support staff, specializing in this procedure. The surgical procedure usually takes about 30 min to complete, and sutures may be necessary to close the site. A needle biopsy usually takes about 15 min to complete.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, analgesics, or IV sedation.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ Have the patient void before the procedure.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**) or seeding of the biopsy tract with tumor cells

- ▶ Ensure that the patient has complied with dietary restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is

dependent on the type of anticoagulant. Notify HCP if patient anticoagulant therapy has not been withheld. Ensure that patients on beta-blocker therapy have continued their medication regimen as ordered.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Assist the patient to the desired position depending on the test site to be used, and direct the patient to breathe normally during the beginning of the general anesthetic. Instruct the patient to cooperate fully and to follow directions. For the patient undergoing local anesthesia, direct him or her to breathe normally and to avoid unnecessary movement during the procedure.
- ▶ Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ After the administration of general or local anesthesia, use clippers to remove hair from the surgical site if appropriate, cleanse the site with an antiseptic solution, and drape the area with sterile towels.

Open Biopsy

- ▶ Adhere to Surgical Care Improvement Project (SCIP) quality measures. Administer ordered prophylactic antibiotics 1 hr before incision, use antibiotics that are consistent with current guidelines specific to the procedure.
- ▶ After administration of general anesthesia and surgical preparation is completed, an incision is made, suspicious area(s) are located, and tissue samples are collected.

Needle Biopsy

- ▶ Instruct the patient to take slow, deep breaths when the local anesthetic is injected. Protect the site with sterile drapes. Instruct the patient to take a deep breath, exhale forcefully, and hold

the breath while the biopsy needle is inserted and rotated to obtain a core of thyroid tissue. Once the needle is removed, the patient may breathe. Pressure is applied to the site for 3 to 5 min, then a sterile pressure dressing is applied.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in properly labeled specimen container containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Discontinue prophylactic antibiotics within 24 hr after the conclusion of the procedure. Protocols may vary among facilities.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to report any redness, edema, bleeding, or pain at the biopsy site.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test. Discuss the implications of the abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of a follow-up appointment for removal of sutures, if indicated. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Genetic testing may be conducted to search for mutations in various genes associated with types of thyroid cancer. Markers associated with a significant incidence of thyroid cancers include BRAF (associated with papillary thyroid cancer), RAS (associated with follicular and papillary thyroid cancers), RET/PTC (associated with an increased risk of developing inherited medullary thyroid cancer, also known as multiple endocrine neoplasia or MEN), and PAX8/PPAR (associated with congenital hypothyroidism and thyroid dysgenesis). Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antibodies, antithyroglobulin, calcitonin and stimulation tests, parathyroid scan,

radioactive iodine uptake, thyroid-binding inhibitory immunoglobulin, thyroid scan, TSH, free thyroxine, and US thyroid.

Refer to the Endocrine and Immune systems tables at the end of the book for related tests by body system.

B

Bioterrorism and Public Health Safety Concerns: Testing for Toxins and Infectious Agents

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in confirming the diagnosis of infection or poisoning in cases of accidental or intentional exposure to agents of high risk to public health safety.

SPECIMEN: The facility or testing laboratory should be contacted regarding specimen collection requirements.

NORMAL FINDINGS: (Method: Disease specific) Negative findings for the organism or toxin of interest; negative serology; negative PCR.

DESCRIPTION: All local and state health departments and the Centers for Disease Control and Prevention (CDC) require health-care providers (HCPs) to report specific diseases/pathogens when they are identified by the requesting HCP or the testing laboratory. Information regarding reportable diseases for each agency can be accessed on their official Web site. This monograph will address some of the pathogens and toxins of biological origin that pose a national security risk through unintended exposure or transmission, use in a military action, or to perpetrate terrorist attacks against civilians. The CDC has grouped biological agents of concern into three categories based on the types of impact to public health that include ease of transmission, high mortality or morbidity rates, and level of action required

for intervention by public health services. A selected sampling from categories A and B are presented in the table below. The full listing can be viewed at the CDC Web site (www.bt.cdc.gov/agent/agentlist-category.asp). Category A includes infectious organisms and toxins that pose the highest risk, Category B includes the next highest risk group, and Category C includes emerging infectious diseases.

The subspecialty of microbiology has been revolutionized by molecular diagnostics. Molecular diagnostics involves the identification of specific sequences of DNA. The application of molecular diagnostics techniques, such as PCR, has led to the development of automated instruments that can identify a single infectious agent or multiple pathogens from a small amount of specimen in less than 2 hr.

Infectious Organism/ Toxin	Disease	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
<i>Bacillus anthracis</i> is a gram-positive, aerobic, rod-shaped, spore-forming bacteria; spores are a dormant form of the bacteria. The composition of the spore confers resistance to unfavorable conditions for growth until a suitable environment is attained.	Anthrax	<i>Bacillus anthracis</i> is found naturally in soil and causes disease in humans when spores from the bacteria are ingested into the GI system in contaminated water, undercooked meat, or cutaneously by handling meat, wool, or hides from infected animals (usually hooved animals in close contact with humans); by inhalation of spores or introduction of spores through breaks in the skin from contaminated animal products; or by an intentional and targeted release of spores in a bioterrorist attack. Infected	<p>Category A</p> <p>The incubation period for anthrax infection is between 1 and 7 days and may vary according to the site of entry with inhalation anthrax having the most rapid progression of symptoms. Symptoms may also vary according to the site of entry. General symptoms include fever, malaise, and vomiting. Papules escalating to skin ulceration and eschar formation are associated with cutaneous anthrax; bloody diarrhea is associated with gastrointestinal (GI) anthrax; severe respiratory distress, pulmonary edema, and development of pleural effusions are associated with inhalation anthrax, advancing to shock, coma, and possible death within 1–3 days after inhalation. Treatment for all forms of anthrax with antibiotics (penicillin, doxycycline, and ciprofloxacin) is usually successful, especially if administered early in the course of the disease. Untreated anthrax of any type or late stage inhaled anthrax may be fatal. Prevention can be enhanced through a veterinary vaccine used for periodic</p>	Specimens considered for testing include blood, stool, skin lesions, sputum, throat culture, body fluids (sputum, ascites, cerebrospinal fluid (CSF), pleural fluid), tissue biopsy, and contaminated food (in the original container if possible). Test methods include culture and gram stain; polymerase chain reaction (PCR); immunochemical techniques (tissue samples); serology; enzyme-linked immunosorbent assays (ELISA). Specimen handling, testing, and

Infectious Organism/ Toxin	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
<p><i>Clostridium botulinum</i> is a gram-positive, anaerobic, rod-shaped, spore-forming bacteria that produces a potent neurotoxin; spores are a dormant form of the bacteria. The composition</p>	<p>individuals are not contagious; the disease is not transmitted directly from person to person.</p>	<p>immunization of livestock, where appropriate. A cell free culture filtrate vaccine prepared from a non-encapsulated strain of <i>Bacillus anthracis</i> is available to individuals in high risk groups (military personnel and other individuals with high exposure risk due to the nature of their jobs). The vaccine is given in a series of five doses over 18 months (three primary doses and two boosters), the effectiveness is not well established, and there is a possibility of significant side effects. The most common type of botulism is food borne, and the incubation period is a few hours to 3 days. Incubation periods for other types of botulism may vary according to the site of entry and can extend up to 1 wk for exposure by wound. Neuromuscular symptoms are the hallmark of how the toxin achieves its effect on the body and include blurred vision, difficulty swallowing, and muscle weakness that progresses to paralysis. Irreversible binding of the toxin to sites where neuromuscular activity is normally initiated prevent the release of a neurotransmitter called acetylcholine. Normal neuromuscular function halts as the body's muscles are irreversibly paralyzed.</p>	<p>culture handling should be performed in a Biosafety Level (BSL) 2 environment.</p>
<p><i>Clostridium botulinum</i> is found naturally in soil and other types of environments, including the human intestine. There are four forms of botulism. The food-borne disease occurs when the bacteria, toxin, or spores are ingested into the GI system in undercooked, contaminated meat, fish, vegetables, sauces, and home-canned foods especially when kept at room temperature after</p>	<p>Botulism</p>	<p>Specimens considered for testing include blood, stool, vomitus, and contaminated food (in the original container if possible). Test methods include mouse neutralization test (to detect the toxin), culture. Specimen handling, testing, and culture handling should be performed in a BSL2 environment.</p>	<p>Specimens considered for testing include blood, stool, vomitus, and contaminated food (in the original container if possible). Infectious Organism/ Toxin	Disease	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
<p>of the spore confers resistance to unfavorable conditions for growth until a suitable environment is attained</p>	<p>cooking. Infants under 1 year of age are susceptible to a type of botulism linked to ingestion of spores in honey. Wound botulism occurs when the bacteria, toxin, or spores are introduced through breaks in the skin. Botulism can also occur by inhalation of spores from a contaminated source or by an intentional and targeted release of spores in a bioterrorist attack. Infected individuals are not contagious; the disease is not transmitted directly from person to person. There are seven distinct botulism neurotoxin types known to affect humans, identified as A, B, C, D, E, F, and G.</p>	<p>Respiratory symptoms may also occur with inhalation botulism. Additional symptoms of infant botulism include other indications of altered neuromuscular function such as poor feeding (due to loss of muscle function related to sucking), constipation (due to loss of muscle function related to elimination), pooled oral secretions (due to loss of muscle function related to swallowing), and loss of head control related to loss of neck muscle strength and function. There is no prescribed treatment for botulism other than palliative care. As the paralysis advances and organ function diminishes, mechanical support is required for breathing and nutrition. A heptavalent vaccine is available for individuals identified as high risk and is effective for clostridial toxin strains A through G. An IV botulism immune globulin is available for infant botulism and is approved for the treatment of botulism types A and B. More information can be obtained from http://www.infantbotulism.org/.</p>		

(table continues on page 280)

Infectious Organism/ Toxin	Disease	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
<i>Francisella tularensis</i> is a gram-negative, aerobic, coccobacillus.	Tularemia	Tularemia can be contracted in a number of different ways: ingestion of the bacteria into the GI system from contaminated water or plants; cutaneously through a break in the skin when handling infected animal products or from the bite of an infected insect, such as a tick or deerfly; or breathing the bacteria into the lungs. Infected individuals are not contagious; the disease is not transmitted directly from person to person.	The incubation period for tularemia averages 3 to 5 days but can take as long as 2 wk, depending on the site of entry. Symptoms may also vary according to the site of entry; the general symptoms of which include fever, chills, headache, diarrhea, weakness, muscle aches, and joint pain. Ingestion of the bacteria can cause symptoms that affect the entire alimentary canal including mouth ulcers, sore throat, swollen and painful lymph glands, intestinal pain, vomiting, and diarrhea. Inhalation of the bacteria can cause symptoms that resemble influenza or pneumonia, such as chest pain from difficulty breathing or bloody sputum. When the infection is introduced cutaneously, skin ulcers and swelling of the associated lymph nodes are evident. The disease can be fatal if it is not treated in a timely manner. Treatment for infection is a 2-wk course of the antibiotic doxycycline or ciprofloxacin. Currently there is no vaccine available in the United States; there is ongoing research to identify an effective vaccine.	Specimens considered for testing include serum, blood, sputum/ throat swab, bronchial/tracheal wash, and stool. Test methods include serology, gram stain, and culture. Specimen handling and testing should be performed in a BSL2 environment; culture handling should be performed in a BSL3 environment.

Infectious Organism/ Toxin	Disease	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
<i>Variola major</i> is a severe and potentially lethal strain of the variola DNA virus.	Smallpox	The smallpox virus is transmitted by an infected human through the respiratory system in droplets that become aerosolized and are inhaled by another person in very close proximity. The smallpox virus can also be transmitted by direct contact with contaminated fomites or direct contact with body fluids from an infected person (secretions from rashes, pustules, or scabs), or by an intentional and targeted bioterrorist attack. The disease can be directly transmitted from person to person.	The incubation period for smallpox averages 12 to 14 days after which general symptoms develop to include fever, headache, and body aches followed by the development of a rash in the mouth and on the skin; the most infectious period is during the first 7 to 10 days following development of the rash. In the next stage of the infection the rash becomes pustular. Eventually the pustules dry up and scab formation occurs. Viable viral particles are present in the scabs; therefore, a person is considered contagious until after the last scab has fallen off. There is no specified treatment for smallpox, and the only prevention is by vaccination. Routine vaccination in the United States ended in 1972 after the disease was eradicated.	Specimens considered for testing include culture, vesicular fluid, skin scraping, and biopsy specimens. Test methods include viral culture or identification from a sample using electron microscopy. Specimen handling, testing, and culture handling should be performed in a BSL4 environment.

(table continues on page 282)

Infectious Organism/ Toxin	Disease	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
<p><i>Filoviruses</i> (e.g., <i>Ebola</i>, <i>Marburg</i>), <i>arenaviruses</i> (e.g., <i>Lassa</i>, <i>Machupo</i>), <i>flaviviruses</i> (including the virus that causes yellow fever), and <i>bunyaviridae</i> (e.g., <i>Haantan</i>).</p> <p>The viruses responsible for viral hemorrhagic fevers (VHFs) are RNA viruses.</p>	VHF	<p>VHFs are a group of severe infections caused by different RNA viruses. The viruses are transmitted to humans cutaneously by way of a bite from an infected reservoir host (e.g., rodent) or infected arthropod vector (e.g., mosquito or tick that has bitten an infected host). Some viruses (e.g., <i>Ebola</i>, <i>Marburg</i>, <i>Lassa</i>) can be directly transmitted from person to person by way of contact with contaminated blood or body fluids. The infection is significant; it can result in multisystem failure</p>	<p>The incubation period for VHFs varies from 3 to 21 days. Beginning symptoms include fever, headache, body aches, fatigue, jaundice, and vomiting; some cases progress with bleeding, shock, and multiorgan failure. There is no prescribed treatment for VHFs, and patients are given supportive treatment for their symptoms. Care should be taken in the selection of medications to reduce fever and pain, avoiding those medications known to increase the risk of bleeding (e.g., salicylates and NSAIDs). Yellow fever is the only VHF for which an effective vaccine is available. Additional preventive measures for yellow fever include avoidance of further exposure to mosquitos by staying indoors during hours when they are most active and using repellents and mosquito netting. Preventive measures decrease the opportunity for uninfected mosquitoes to feed on infected blood, which in turn decreases the spread of the disease.</p>	<p>Specimens considered for testing include serum, blood, sputum, and tissue. Test methods include viral isolation, PCR, ELISA, immunohistochemistry of tissue, and serology. Specimen handling, testing, and culture handling for yellow fever should be performed in a BSL3; for dengue should be performed in a BSL2; for others should be performed in a BSL4 environment.</p>

Infectious Organism/ Toxin	Disease	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
<i>Yersinia pestis</i> is a gram-negative, facultatively anaerobic, obligate intracellular coccobacillus.	Plague	and death. Because some viruses have the potential to cause massive numbers of deaths through contagious infection they are considered possible weapons for use in an intentional and targeted bioterrorist attack. There are three forms of plague. The first and probably best known is bubonic plague. The reservoir host (usually a rodent) carries infected fleas; the fleas spread the disease cutaneously to humans through a bite. The bacteria multiply in the lymph node closest to the site of the flea bite. Septicemic plague occurs when the bacteria	The average incubation period for plague is 1 to 6 days depending on the site of entry; generally pneumonic plague has a shorter incubation period. General symptoms include fever, chills, enlarged lymph nodes, malaise, septicemia, hemorrhagic skin changes, pneumonia (pneumonic plague), shock, and death. Early identification and administration of antibiotics (tetracycline or fluoroquinolone) for 7 days, with supportive care is the most effective treatment for plague. Currently there is no FDA-approved vaccine available.	Specimens considered for testing include serum, blood, sputum/throat swab, bronchial/tracheal wash, and lymph node aspirate. Test methods include serology, gram stain, and culture. Specimen and culture handling should be performed in a BSL2 environment.

(table continues on page 284)

Infectious Organism/ Toxin	Disease	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
		<p>is inoculated into the bloodstream by flea bite or by the bite of an infected animal. Pneumonic plague is the most lethal form of plague. It occurs when the infection from either untreated bubonic or septicemic plague spreads to the lungs. Pneumonic is the only form of plague that can be transmitted person to person from inhalation of aerosolized droplets of contaminated fluid, direct contact with contaminated fomites (for short periods of time), or by an intentional and targeted bioterrorist attack.</p>		

Infectious Organism/ Toxin	Disease	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
<i>Brucella abortus</i> , <i>B. suis</i> , <i>B. melitensis</i> , or <i>B. canis</i> ; the species are gram-negative, aerobic, cocci	Brucellosis	Infection occurs after ingestion into the GI system from infected meats and contaminated milk products (especially goat's milk), direct puncture of the skin (by butchers and farmers), or by inhalation. It is not a contagious disease that is transmitted from person to person.	<p>Category B</p> <p>The average incubation period for brucellosis infection is 1 to 2 mo. General symptoms include fever, chills, headache, night sweats, back pain, joint pain, and malaise. The disease is systemic, affecting multiple organs and body systems. Brucellosis can be effectively treated with antibiotics (e.g., doxycycline, tetracycline, streptomycin, bactrim, rifampin, ciprofloxacin, or gentamicin). Currently there is no vaccine available for use in humans.</p>	Specimens considered for testing include serum, blood, bone marrow, spleen or liver tissue, sputum, and food. Test methods include serology, gram stain, culture, and immunofluorescence. Specimen handling should be performed in a BSL2 environment; culture handling should be performed in a BSL3 environment.
<i>Ricinus communis</i> is the name for the castor oil plant. The plant's seeds	Ricin poisoning. The toxin is released after ingestion of castor beans. It can also be	Ricin poisoning occurs by ingestion into the GI system or by inhalation into the respiratory system. It is not a contagious disease that	Symptoms of ricin poisoning vary based on the site of entry and concentration of the dose. If the toxin is ingested, GI symptoms such as nausea, pain, and vomiting appear in 6 to 12 hr; if the toxin is inhaled, respiratory symptoms such as difficulty breathing,	Environmental samples can be tested for the presence of ricin by time-resolved fluorescence immunoassay and

(table continues on page 286)

Infectious Organism/ Toxin	Disease	Mode of Transmission and Site of Entry	Incubation Period, Signs, Symptoms, and Treatment	Specimen Required and Test Method
<p>contain an oil composed mostly of the lipid ricinolein and smaller amounts of ricin, a powerful toxin.</p>	<p>purposely made from a waste product generated in the normal production of castor oil. The toxin can then be used in an intentional and targeted bioterrorist attack.</p>	<p>is transmitted from person to person, and the likelihood of accidental poisoning is very low. The manufactured toxin can be released as a powder into the air or dissolved in water supplies. Very small amounts could sicken and kill large numbers of people and for this reason it is considered as a potential weapon for use in an intentional and targeted bioterrorist attack.</p>	<p>coughing, and chest pain appear in 4 to 6 hr. Over the next 12 to 24 hr the symptoms will rapidly escalate toward organ failure. Ricin affects the body at the cellular level by preventing the production of proteins, an essential process for every living cell, tissue, and organ. Presently there are no methods available for the detection of ricin in biological fluids. Diagnosis of ricin poisoning is made using general laboratory tests for evidence of the effects of the toxin on the body and is arrived at within the context of high suspicion of exposure. Lab results of interest might include elevated liver function results, elevated renal function results, abnormal urinalysis findings such as blood in the urine, and moderate to very increased WBC count (two to five times normal levels).</p>	<p>PCR. Specimen handling should be performed in a BSL2 or BSL3 environment depending on the possibility of aerosolization and concentration of toxin submitted for testing.</p>

This procedure is contraindicated for: N/A

INDICATIONS

- Suspected infection by high-risk pathogen (***demonstrated by associated signs and symptoms or known exposure***)

POTENTIAL DIAGNOSIS

Positive findings in

- Positive findings for the organism or toxin of interest; positive serology. Refer to the table in the Description section for details.

CRITICAL FINDINGS

- Positive findings for a disease listed in Description section leads to a high likelihood of being required for reporting to local, state, and/or federal health departments.

INTERFERING FACTORS

- Failure to follow the appropriate specimen collection and transport procedures may affect the validity of the results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ ***Patient Teaching:*** Inform the patient this test can assist in assessing for infection or poisoning.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of exposure, including all possible sources (e.g.,

environmental, other individuals who are ill with similar symptoms, food, animals, etc.).

- ▶ Obtain a history of the patient's immune system, a history of other potential sources of exposure, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm the diagnosis. Any individual positive serology result may be repeated in 3 wk to monitor a change in detectable level of antibody, as appropriate. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain, and explain that there may be some discomfort during the venipuncture.
- ▶ ***Sensitivity to social and cultural issues,*** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction; as a general rule specimens should be collected prior to administration of antibiotics whenever possible. Chain of custody policies may be required in cases of intentional exposure.

INTRATEST:

- ▶ **Potential Complications:** N/A
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Contact the testing laboratory prior to specimen collection in order to obtain accurate information regarding

specimen collection containers, sample volumes, and specific transport instructions.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Collect the appropriate specimen as described in the related body fluid analysis or culture monograph. The facility or testing laboratory should be contacted for guidelines regarding chain of custody, specimen collection requirements, and specimen packaging and shipping instructions.
- ▶ Perform a venipuncture if blood is the specimen required for testing. Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and provide emotional support if results are positive. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient in isolation precautions during time of communicability or contagion, as appropriate. Instruct the patient in the proper way to decontaminate solid surfaces with a 1:10 dilution of household bleach; to decontaminate clothing; to "cover a cough;" and to perform good hand hygiene.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed. Emphasize the need to return to have a convalescent blood sample taken in 3 wk, if ordered. Answer any questions or address any concerns voiced by the patient or family.

RELATED MONOGRAPHS:

- ▶ Related tests include acetylcholine receptor antibodies, basic metabolic panel, biopsy lung, biopsy lymph node, bronchoscopy, chest x-ray, CSF analysis, comprehensive metabolic panel, CT chest, culture throat, culture blood, culture sputum, culture stool, liver function tests, peritoneal fluid analysis, pleural fluid analysis, and renal function tests.
- ▶ Refer to the Gastrointestinal, Genitourinary, Hematopoietic, Hepatobiliary, Immune, Musculoskeletal, and Respiratory System tables at the end of the book for related tests by body system.

Bladder Cancer Markers, Urine

SYNONYM/ACRONYM: Nuclear matrix protein (NMP) 22, BTA, cytogenic marker for bladder cancer.

COMMON USE: To assist in diagnosing bladder cancer.

SPECIMEN: Urine (5 mL), unpreserved random specimen collected in a clean plastic collection container for NMP22 and Bard BTA; urine (30 mL), first void specimen collected in fixative specific for FISH testing.

NORMAL FINDINGS: (Method: Enzyme immunoassay for NMP22 and bladder tumor antigen [BTA], fluorescence in situ hybridization [FISH] for cytogenic marker)

NMP22: Negative: Less than 6 units/mL, borderline: 6 to 10 units/mL, positive: Greater than 10 units/mL

BTA: Negative

Cytogenic Marker: Negative

DESCRIPTION: Cystoscopy is still considered the gold standard for detection of bladder cancer, but other noninvasive tests have been developed, including several urine assays approved by the U.S. Food and Drug Administration.

Compared to cytological studies, these assays are believed to be more sensitive but less specific for detecting transitional cell carcinoma. FISH is a cytogenic technique that uses fluorescent-labeled DNA probes to detect specific chromosome abnormalities. The FISH bladder cancer assay specifically detects the presence of aneuploidy for chromosomes 3, 7, and 17 and absence of the 9p21 loci, findings associated with transitional cell cancer of the bladder.

NMP22: Nuclear matrix proteins (NMPs) are involved in the regulation and expression of various genes. The NMP identified as NuMA is abundant in bladder tumor cells. The dying tumor cells release the soluble NMP into the urine. This assay is quantitative.

Bladder tumor antigen (BTA): A human complement factor H-related protein (hCFHrp) is thought to be produced by bladder tumor cells as protection from the body's natural immune response. BTA is released from tumor cells into the urine. This assay is qualitative.

This procedure is contraindicated for: N/A

INDICATIONS

- Detection of bladder carcinoma
- Management of recurrent bladder cancer

POTENTIAL DIAGNOSIS

Increased in bladder carcinoma.

CRITICAL FINDINGS

- Bladder carcinoma

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- **NMP22:** Any condition that results in inflammation of the bladder or urinary tract may cause falsely elevated values.
- **BTA:** Recent surgery, biopsy, or other trauma to the bladder or urinary tract may cause falsely elevated values. Bacterial overgrowth from active urinary tract infection, renal or bladder calculi, gross contamination from blood, and positive leukocyte dipstick may also cause false-positive results.
- **Cytogenic marker:** Incorrect fixative, gross contamination from blood, bacterial overgrowth from active urinary tract infection, inadequate number of bladder cells in specimen.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this procedure can assist in establishing a diagnosis of bladder disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there should be no discomfort during the procedure. Inform the patient that specimen collection takes approximately 5 min, depending on the cooperation and ability of the patient.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection.
- ▶ Obtain urine specimen in a clean plastic collection container. Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Society (www.cancer.org) or the National Cancer Institute (www.cancer.gov).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. The greatest risk factor for bladder cancer is smoking. Inform the patient of smoking cessation programs as

appropriate. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bladder, cytology urine, cystoscopy, IVP, and US bladder.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Bleeding Time

SYNONYM/ACRONYM: Mielke bleeding time, Simplate bleeding time, template bleeding time, Surgicutt bleeding time, Ivy bleeding time.

COMMON USE: To evaluate platelet function.

SPECIMEN: Whole blood.

NORMAL FINDINGS: (Method: Timed observation of incision)

Template: 2.5 to 10 min

Ivy: 2 to 7 min

Slight differences exist in the disposable devices used to make the incision. Although the Mielke or template bleeding time is believed to offer greater standardization to a fairly subjective procedure, both methods are thought to be of equal sensitivity and reproducibility.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

This test does not predict excessive bleeding during a surgical procedure.

Prolonged In

- Bernard-Soulier syndrome (*evidenced by a rare hereditary condition in which platelet glycoprotein GPIb is deficient and platelet aggregation is decreased*)

- Fibrinogen disorders (*related to the role of fibrinogen to help platelets link together*)
- Glanzmann's thrombasthenia (*evidenced by a rare hereditary condition in which platelet glycoprotein IIb/IIIa is deficient and platelet aggregation is decreased*)
- Hereditary telangiectasia (*evidenced by fragile blood vessels that do not permit adequate constriction to stop bleeding*)
- Liver disease (*related to decreased production of coagulation proteins that affect bleeding time*)
- Some myeloproliferative disorders (*evidenced by disorders of decreased platelet production*)
- Renal disease (*related to abnormal platelet function*)
- Thrombocytopenia (*evidenced by insufficient platelets to stop bleeding*)
- von Willebrand's disease (*evidenced by deficiency of von Willebrand factor, necessary for normal platelet adhesion*)

Decreased in: N/A

CRITICAL FINDINGS

Greater than 14 min

Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms.

It is essential that critical findings be communicated immediately to the requesting HCP. Listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional

nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Potential nursing interventions for bleeding include applying pressure to the incision until the bleeding stops and covering the incision site with a bandage. Some people are more prone than others to develop scars or keloids. Generally, they are pink to reddish in color, raised, and shinier than the surrounding skin. They can be itchy, tender, or even painful to the touch. There is no immediate intervention to prevent the formation of scars or keloids. Treatment options for developed scars and keloids range from cortisone injections to a variety of strategies for removal, each of which can vary widely in degree of success. The site should be observed for subsequent bleeding, bruising, or redness. Fever, localized redness, or warmth of the area to the touch may be indications of infection. Potential nursing interventions include monitoring temperature as well as administering antipyretic and antibiotic medications, as ordered.

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen)

Blood Gases

SYNONYM/ACRONYM: Arterial blood gases (ABGs), venous blood gases, capillary blood gases, cord blood gases.

COMMON USE: To assess oxygenation and acid base balance.

SPECIMEN: Whole blood. Specimen volume and collection container may vary with collection method. See Intratest section for specific collection instructions. Specimen should be tightly capped and transported in an ice slurry.

NORMAL FINDINGS: (Method: Selective electrodes for pH, Pco₂ and Po₂)

Blood Gas Value (pH)	Arterial	Venous	Capillary

DESCRIPTION: Blood gas analysis is used to evaluate respiratory function and provide a measure for determining acid-base balance. Respiratory, renal, and cardiovascular system functions are integrated in order to maintain normal acid-base balance. Therefore, respiratory or metabolic disorders may cause abnormal blood gas findings. The blood gas measurements commonly reported are pH, partial pressure of carbon dioxide in the blood (Pco_2), partial pressure of oxygen in the blood (Po_2), bicarbonate (HCO_3^-), O_2 saturation, and base excess (BE) or base deficit (BD). pH reflects the number of free hydrogen ions (H^+) in the body. A pH less than 7.35 indicates acidosis. A pH greater than 7.45 indicates alkalosis. Changes in

the ratio of free H^+ to HCO_3^- will result in a compensatory response from the lungs or kidneys to restore proper acid-base balance.

Pco_2 is an important indicator of ventilation. The level of Pco_2 is controlled primarily by the lungs and is referred to as the respiratory component of acid-base balance. The main buffer system in the body is the bicarbonate-carbonic acid system. Bicarbonate is an important alkaline ion that participates along with other anions, such as hemoglobin, proteins, and phosphates, to neutralize acids. For the body to maintain proper balance, there must be a ratio of 20 parts bicarbonate to one part carbonic acid (20:1). Carbonic acid level is indirectly measured by Pco_2 . Bicarbonate

level is indirectly measured by the total carbon dioxide content ($T\text{CO}_2$). The carbonic acid level is not measured directly but can be estimated because it is 3% of the PCO_2 . Bicarbonate can also be calculated from these numbers once the carbonic acid value has been obtained because of the 20:1 ratio. For example, if the PCO_2 were 40, the carbonic acid would be calculated as $(3\% \times 40)$ or 1.2, and the HCO_3^- would be calculated as (20×1.2) or 24. The main acid in the acid-base system is carbonic acid. It is the metabolic or nonrespiratory component of the acid-base system and is controlled by the kidney. Bicarbonate levels can either be measured directly or estimated from the $T\text{CO}_2$ in the blood. BE/BD reflects the number of anions available in the blood to help buffer changes in pH. A BD (negative BE) indicates metabolic acidosis, whereas a positive BE indicates metabolic alkalosis.

Extremes in acidosis are generally more life threatening than alkalosis. Acidosis can develop either very quickly (e.g., cardiac arrest) or over a longer period of time (e.g., renal failure). Infants can develop acidosis very quickly if they are not kept warm and given enough calories. Children with diabetes tend to go into acidosis more quickly than do adults who have been dealing with the disease over a longer period of time. In many cases, a venous or capillary specimen is satisfactory to obtain the necessary information regarding acid-base balance without subjecting the patient to an arterial puncture with its associated risks.

As seen in the table of reference ranges, PO_2 is lower in infants than in children and adults owing to the respective level of maturation of the lungs at birth. PO_2 tends to trail off after age 30, decreasing by approximately 3 to 5 mm Hg per decade as the organs age and begin to lose elasticity. The formula used to approximate the relationship between age and PO_2 is:

$$\text{PO}_2 = 104 - (\text{age} \times 0.27)$$

Like carbon dioxide, oxygen is carried in the body in a dissolved and combined (oxyhemoglobin) form. Oxygen content is the sum of the dissolved and combined oxygen. The oxygen-carrying capacity of the blood indicates how much oxygen could be carried if all the hemoglobin were saturated with oxygen. Percentage of oxygen saturation is $[\text{oxyhemoglobin concentration} \div (\text{oxyhemoglobin concentration} + \text{deoxyhemoglobin concentration})] \times 100$.

Testing on specimens other than arterial blood is often ordered when oxygen measurements are not needed or when the information regarding oxygen can be obtained by noninvasive techniques such as pulse oximetry. Capillary blood is satisfactory for most purposes for pH and PCO_2 ; the use of capillary PO_2 is limited to the exclusion of hypoxia. Measurements involving oxygen are usually not useful when performed on venous samples; arterial blood is required to accurately measure PO_2 and oxygen saturation. Considerable evidence indicates that prolonged exposure to high levels of oxygen can result in injury, such as retinopathy of

prematurity in infants or the drying of airways in any patient. Monitoring Po_2 from blood gases is especially appropriate under such circumstances.

This procedure is contraindicated for

Arterial puncture in any of the following circumstances:

-  Inadequate circulation *as evidenced by an abnormal (negative) Allen test or the absence of a radial artery pulse*
-  Significant or uncontrolled bleeding disorder *as the procedure may cause excessive bleeding*; caution should be used when performing an arterial puncture on patients receiving anticoagulant therapy or thrombolytic medications
-  Infection at the puncture site *carries the potential for introducing bacteria from the skin surface into the blood stream*
-  Congenital or acquired abnormalities of the skin or blood vessels in the area of the anticipated puncture site such as

arteriovenous fistulas, burns, tumors, vascular grafts

INDICATIONS

This group of tests is used to assess conditions such as asthma, chronic obstructive pulmonary disease (COPD), embolism (e.g., fatty or other embolism) during coronary arterial bypass surgery, and hypoxia. It is also used to assist in the diagnosis of respiratory failure, which is defined as a Po_2 less than 50 mm Hg and Pco_2 greater than 50 mm Hg. Blood gases can be valuable in the management of patients on ventilators or being weaned from ventilators. Blood gas values are used to determine acid-base status, the type of imbalance, and the degree of compensation as summarized in the following section. Restoration of pH to near-normal values is referred to as fully compensated balance. When pH values are moving in the same direction (i.e., increasing or decreasing) as the Pco_2 or HCO_3^- , the imbalance is metabolic. When the pH values are moving in the opposite direction from the Pco_2 or HCO_3^- , the imbalance is caused by respiratory disturbances. To remember this concept, the following mnemonic can be useful: **MeTRO = Metabolic Together, Respiratory Opposite.**

Acid-Base Disturbance	pH	Pco_2	Po_2	HCO_3^-
<i>Respiratory Acidosis</i>				
Uncompensated	Decreased	Increased	Normal	Normal
Compensated	Normal	Increased	Increased	Increased
<i>Respiratory Alkalosis</i>				
Uncompensated	Increased	Decreased	Normal	Normal
Compensated	Normal	Decreased	Decreased	Decreased
Uncompensated	Decreased	Normal	Decreased	Decreased
Compensated	Normal	Decreased	Decreased	Decreased
<i>Metabolic (Nonrespiratory) Acidosis</i>				
Uncompensated	Increased	Normal	Increased	Increased
Compensated	Normal	Increased	Increased	Increased

POTENTIAL DIAGNOSIS

Acid-base imbalance is determined by evaluating pH, P_{CO_2} , and HCO_3^- values. pH less than 7.35 reflects an acidic state, whereas pH greater than 7.45 reflects alkalosis. P_{CO_2} and HCO_3^- determine whether the imbalance is respiratory or nonrespiratory (metabolic). Because a patient may have more than one imbalance and may also be in the process of compensating, the interpretation of blood gas values may not always seem straightforward.

Respiratory conditions that interfere with normal breathing cause CO_2 to be retained in the blood. This results in an increase of circulating carbonic acid and a corresponding decrease in pH (respiratory acidosis). Acute respiratory acidosis can occur in acute pulmonary edema, severe respiratory infections, bronchial obstruction, pneumothorax, hemothorax, open chest wounds, opiate poisoning, respiratory depressant drug therapy, and inhalation of air with a high CO_2 content. Chronic respiratory acidosis can be seen in patients with asthma, pulmonary fibrosis, emphysema, bronchiectasis, and respiratory depressant drug therapy. Respiratory conditions that increase the breathing rate cause CO_2 to be removed from the alveoli more rapidly than it is being produced. This results in an alkaline pH. Acute respiratory alkalosis may be seen in anxiety, hysteria, hyperventilation, and pulmonary embolus and with an increase in artificial ventilation. Chronic respiratory alkalosis may be seen in high fever, administration of drugs (e.g., salicylate and sulfa) that stimulate the respiratory system, hepatic coma, hypoxia of high altitude, and central

nervous system (CNS) lesions or injury that result in stimulation of the respiratory center.

Metabolic (nonrespiratory) conditions that cause the excessive formation or decreased excretion of organic or inorganic acids result in metabolic acidosis. Some of these conditions include ingestion of salicylates, ethylene glycol, and methanol, as well as uncontrolled diabetes, starvation, shock, renal disease, and biliary or pancreatic fistula. Metabolic alkalosis results from conditions that increase pH, as can be seen in excessive intake of antacids to treat gastritis or peptic ulcer, excessive administration of HCO_3^- , loss of stomach acid caused by protracted vomiting, cystic fibrosis, or potassium and chloride deficiencies.

Respiratory Acidosis

- Decreased pH
- Decreased O_2 saturation
- Increased P_{CO_2} :
 - Acute intermittent porphyria
 - Anemia (severe)
 - Anorexia
 - Anoxia
 - Asthma
 - Atelectasis
 - Bronchitis
 - Bronchoconstriction
 - Carbon monoxide poisoning
 - Cardiac disorders
 - Congenital heart defects
 - Congestive heart failure
 - COPD
 - Cystic fibrosis
 - Depression of respiratory center
 - Drugs depressing the respiratory system
 - Electrolyte disturbances (severe)
 - Emphysema
 - Fever
 - Head injury
 - Hypercapnia
 - Hypothyroidism (severe)

Near drowning
 Pleural effusion
 Pneumonia
 Pneumothorax
 Poisoning
 Poliomyelitis
 Pulmonary edema
 Pulmonary embolism
 Pulmonary tuberculosis
 Respiratory distress syndrome (adult and neonatal)
 Respiratory failure
 Sarcoidosis
 Smoking
 Tumor

• **A decreased P_{O_2} that increases P_{CO_2} :**

Decreased alveolar gas exchange:
 cancer, compression or resection of lung, respiratory distress syndrome (newborns), sarcoidosis

Decreased ventilation or perfusion: asthma, bronchiectasis, bronchitis, cancer, croup, cystic fibrosis (mucoviscidosis), emphysema, granulomata, pneumonia, pulmonary infarction, shock

Hypoxemia: anesthesia, carbon monoxide exposure, cardiac disorders, high altitudes, near drowning, presence of abnormal hemoglobins

Hypoventilation: cerebrovascular incident, drugs depressing the respiratory system, head injury

Right-to-left shunt: congenital heart disease, intrapulmonary venoarterial shunting

Compensation

- **Increased P_{O_2} :**
Hyperbaric oxygenation
Hyperventilation
- **Increased base excess:**
Increased HCO_3^- to bring pH to (near) normal

Respiratory Alkalosis

- **Increased pH**
- **Decreased P_{CO_2} :**
Anxiety
CNS lesions or injuries that cause stimulation of the respiratory center

Excessive artificial ventilation
 Fever
 Head injury
 Hyperthermia
 Hyperventilation
 Hysteria
 Salicylate intoxication

Compensation

- **Decreased P_{O_2} :**
Rebreather mask
- **Decreased base excess:**
Decreased HCO_3^- to bring pH to (near) normal

Metabolic Acidosis

- **Decreased pH**
- **Decreased HCO_3^-**
- **Decreased base excess**
- **Decreased T_{CO_2} :**
Decreased excretion of H^+ : acquired (e.g., drugs, hypercalcemia), Addison's disease, diabetic ketoacidosis, Fanconi's syndrome, inherited (e.g., cystinosis, Wilson's disease), renal failure, renal tubular acidosis
Increased acid intake
Increased formation of acids: diabetic ketoacidosis, high-fat/low-carbohydrate diets
Increased loss of alkaline body fluids: diarrhea, excess potassium, fistula
Renal disease

Compensation

- **Decreased P_{CO_2} :**
Hyperventilation

Metabolic Alkalosis

- **Increased pH**
- **Increased HCO_3^-**
- **Increased base excess**
- **Increased T_{CO_2} :**
Alkali ingestion (excessive)
Anoxia
Gastric suctioning
Hypochloremic states
Hypokalemic states
Potassium depletion: Cushing's disease, diarrhea, diuresis, excessive vomiting,

excessive ingestion of licorice, inadequate potassium intake, potassium-losing nephropathy, steroid administration

Salicylate intoxication

Shock

Vomiting

Compensation

- Increased T_{CO_2} :
Hypoventilation

CRITICAL FINDINGS

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Arterial Blood Gas Parameter		Less Than	Greater Than
Adult/child	pH	7.2	7.6
Adult/child	HCO_3^-	10 mmol/L	40 mmol/L
Adult/child	P_{CO_2}	20 mm Hg (SI: 2.7 kPa)	67 mm Hg (SI: 8.9 kPa)
Adult/child	PO_2	45 mm Hg (SI: 6 kPa)	
Newborns	PO_2	37 mm Hg (SI: 4.9 kPa)	92 mm Hg (SI: 12.2 kPa)

INTERFERING FACTORS

- Drugs that may cause an increase in HCO_3^- include acetylsalicylic acid (initially), antacids, carbenicillin, carbenoxolone, ethacrynic acid, glycyrrhiza (licorice), laxatives, mafenide, and sodium bicarbonate.
- Drugs that may cause a decrease in HCO_3^- include acetazolamide, acetylsalicylic acid (long term or high doses), citrates, dimethadione, ether, ethylene glycol, fluorides, mercury compounds (laxatives), methylenedioxymphetamine, paraldehyde, and xylitol.
- Drugs that may cause an increase in P_{CO_2} include acetylsalicylic acid, aldosterone bicarbonate, carbenicillin, carbenoxolone, corticosteroids, dexamethasone, ethacrynic acid, laxatives (chronic abuse), and x-ray contrast agents.
- Drugs that may cause a decrease in P_{CO_2} include acetazolamide, acetylsalicylic acid, ethamivan, neuromuscular relaxants (secondary to postoperative hyperventilation), NSD 3004 (arterial long-acting carbonic anhydrase inhibitor), theophylline, tromethamine, and xylitol.

- Drugs that may cause an increase in Po_2 include theophylline and urokinase.
- Drugs that may cause a decrease in Po_2 include althesin, barbiturates, granulocyte-macrophage colony-stimulating factor, isoproterenol, and meperidine.
- Samples for blood gases are obtained by arterial puncture, which carries a risk of bleeding, especially in patients who have bleeding disorders or are taking anticoagulants or other blood thinning medications.
- Recent blood transfusion may produce misleading values.
- Specimens with extremely elevated white blood cell counts will undergo misleading decreases in pH resulting from cellular metabolism, if transport to the laboratory is delayed.
- Specimens collected soon after a change in inspired oxygen has occurred will not accurately reflect the patient's oxygenation status.
- Specimens collected within 20 to 30 min of respiratory passage suctioning or other respiratory therapy will not be accurate.
- Excessive differences in actual body temperature relative to normal body temperature will not be reflected in the results. Temperature affects the amount of gas in solution. Blood gas analyzers measure samples at 37°C (98.6°F); therefore, if the patient is hyperthermic or hypothermic, it is important to notify the laboratory of the patient's actual body temperature at the time the specimen was collected. Fever will increase actual Po_2 and Pco_2 values; therefore, the uncorrected values measured at 37°C will be falsely decreased. Hypothermia decreases actual Po_2 and Pco_2 values; therefore, the uncorrected values measured at 37°C will be falsely increased.
- A falsely increased O_2 saturation may occur because of elevated levels of carbon monoxide in the blood.
- O_2 saturation is a calculated parameter based on an assumption of 100% hemoglobin A. Values may be misleading when hemoglobin variants with different oxygen dissociation curves are present. Hemoglobin S will cause a shift to the right, indicating decreased oxygen binding. Fetal hemoglobin and methemoglobin will cause a shift to the left, indicating increased oxygen binding.
- Excessive amounts of heparin in the sample may falsely decrease pH, Pco_2 , and Po_2 .
- Citrates should never be used as an anticoagulant in evacuated collection tubes for venous blood gas determinations because citrates will cause a marked analytic decrease in pH.
- Air bubbles or blood clots in the specimen are cause for rejection. Air bubbles in the specimen can falsely elevate or decrease the results depending on the patient's blood gas status. If an evacuated tube is used for venous blood gas specimen collection, the tube must be removed from the needle before the needle is withdrawn from the arm or else the sample will be contaminated with room air.
- Specimens should be placed in ice slurry immediately after collection because blood cells continue to carry out metabolic processes in the specimen after it has been removed from the patient. These natural life processes can affect pH, Po_2 , Pco_2 , and the other calculated

values in a short period of time. The cold temperature provided by the ice slurry will slow down, but not completely stop, metabolic changes occurring in the sample over time. Iced specimens not

analyzed within 60 min of collection should be rejected for analysis. Electrolyte analysis from iced specimens should be carried out within 30 min of collection to avoid falsely elevated potassium values.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Gas exchange <i>(Related to altered alveolar and capillary exchange; ventilation-perfusion mismatch; compromised oxygen supply; inadequate oxygen-carrying capacity of the blood)</i>	Confusion, restlessness, hypoxia, irritability, shortness of breath, altered blood gases, orthopnea, cyanosis, increased heart rate, increased respiratory rate, use of respiratory accessory muscles, elevated blood pressure	Auscultate and trend breath sounds (adventitious breath sound); assess respiratory rate, rhythm, depth, and accessory muscle use; assess for symptoms of infection, atelectasis, consolidation, and pleural effusion; assess for restlessness, dizziness, lethargy, disorientation, and confusion; monitor and trend HGB; monitor chest x-ray reports; use pulse oximetry to monitor oxygenation; administer oxygen as ordered; collaborate with physician to consider intubation and/or mechanical ventilation; place the head of the bed in high Fowler's position; administer diuretics, vasodilators as ordered; monitor arterial blood gas results
Tissue perfusion <i>(Related to compromised cardiac contractility; interrupted blood flow; inadequate oxygen)</i>	Hypotension; dizziness; cool extremities; capillary refill greater than 3 sec; weak pedal pulses; altered level of consciousness;	Monitor blood pressure (orthostatic); assess for dizziness; check skin temperature for warmth; assess capillary refill; assess pedal pulses; monitor level of consciousness; administer prescribed IV fluids; administer prescribed

Problem	Signs & Symptoms	Interventions
<i>transportation; decreased HGB; hypoventilation; hypovolemia)</i>	weak or absent peripheral pulses; compromised sensation; poor healing; cool, clammy skin	vasodilator, antiplatelet, anticoagulant, and inotropic drugs; administer oxygen as required
Breathing (<i>Related to inflammation; viral or bacterial infection; muscular impairment; tracheal or bronchial obstruction; compromised neuromuscular function; spinal cord injury)</i>	Shortness of breath, rapid breathing, slow breathing, nasal flare; use of accessory muscles; changes in respiratory effort and depth; cyanosis; pursed lip breathing; bending forward to breathe easier	Assess respiratory rate, rhythm, and depth; assess for use of accessory muscles; monitor for nasal flare with ventilation; assess for adventitious breath sounds; monitor for anxiety; monitor and trend blood gas results; pulse oximetry to monitor and trend oxygenation; administer of prescribed oxygen; administer of ordered antibiotics or antivirals; discuss positions that will improve ventilation and oxygenation; pace activities to match patient energy stores; consider future need for mechanical ventilation
Cardiac output (<i>Related to altered ventricular filling; impaired contractility; increased afterload; altered conductivity; decreased oxygenation; cardiac disease)</i>	Hypotension; increased heart rate; decreased cardiac output; decreased oxygen saturation; decreased peripheral pulses; decreased urinary output; cool, clammy skin; tachypnea; dyspnea; edema; altered level of consciousness; abnormal heart	Assess peripheral pulses and capillary refill; monitor blood pressure and check for orthostatic changes; assess respiratory rate, breath sounds, and orthopnea; assess skin color and temperature; assess level of consciousness; monitor urinary output; use pulse oximetry to monitor oxygenation; monitor sodium and potassium levels; monitor BNP levels; administer ordered ACE inhibitors, antidysrhythmics;

(table continues on page 304)

Problem	Signs & Symptoms	Interventions
	sounds; crackles in lungs; decreased activity tolerance; weight gain; fatigue; hypoxia; decreased ejection fraction (less than 40%)	diuretics, vasodilators, inotropics; provide oxygen administration

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing blood oxygen balance and oxygenation level.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex and anesthetics.
- ▶ Obtain a history of the patient's cardiovascular, genitourinary, and respiratory systems, any bleeding disorders or other symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Record the patient's temperature.
- ▶ Indicate the type of oxygen, mode of oxygen delivery, and delivery rate as part of the test requisition process. Wait 30 min after a change in type or mode of oxygen delivery or rate for specimen collection.
- ▶ Review the procedure with the patient and advise rest for 30 min before specimen collection. Explain to the patient that an arterial puncture may be painful. The site may be anesthetized with 1% to 2% lidocaine before puncture. Inform the patient that specimen collection and postprocedure care of the puncture site usually take 10 to 15 min. The person collecting the specimen should be notified

beforehand if the patient is receiving anticoagulant therapy or taking aspirin or other natural products that may prolong bleeding from the puncture site.

- ▶  If the sample is to be collected by radial artery puncture, perform an Allen test before puncture to ensure that the patient has adequate collateral circulation to the hand if thrombosis of the radial artery occurs after arterial puncture. The modified Allen test is performed as follows: Extend the patient's wrist over a rolled towel. Ask the patient to make a fist with the hand extended over the towel. Use the second and third fingers to locate the pulses of the ulnar and radial arteries on the palmar surface of the wrist. (The thumb should not be used to locate these arteries because it has a pulse.) Compress both arteries and ask the patient to open and close the fist several times until the palm turns pale. Release pressure on the ulnar artery only. Color should return to the palm within 5 sec if the ulnar artery is functioning. This is a positive Allen test, and blood gases may be drawn from the radial artery site. The Allen test should then be performed on the opposite hand. The hand to which color is restored fastest has better circulation and should be selected for specimen collection.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory.

INTRATEST:**Potential Complications:** N/A

Bleeding, pain, hematoma

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform an arterial puncture.

Arterial

- ▶ Perform an arterial puncture and collect the specimen in an air-free heparinized syringe. There is no demonstrable difference in results between samples collected in plastic syringes and samples collected in glass syringes. It is very important that no room air be introduced into the collection container because the gases in the room and in the sample will begin equilibrating immediately. The end of the syringe must be stoppered immediately after the needle is withdrawn and removed. Apply a pressure dressing over the puncture site. Samples should be mixed by gently rolling the syringe to ensure proper mixing of the heparin with the sample, which prevents the formation of small clots leading to rejection of the sample. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the

specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

Venous

- ▶ Central venous blood is collected in a heparinized syringe.
- ▶ Venous blood is collected percutaneously by venipuncture in a 5-mL green-top (heparin) tube (for adult patients) or a heparinized Microtainer (for pediatric patients). The vacuum collection tube must be removed from the needle before the needle is removed from the patient's arm. Apply a pressure dressing over the puncture site. Samples should be mixed by gently rolling the syringe to ensure proper mixing of the heparin with the sample, which prevents the formation of small clots leading to rejection of the sample. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

Capillary

- ▶ Perform a capillary puncture and collect the specimen in two 250- μ L heparinized capillaries (scalp or heel for neonatal patients) or a heparinized Microtainer (for pediatric patients). Observe standard precautions and follow the general guidelines in Appendix A. The capillary tubes should be filled as much as possible and capped on both ends. Some hospitals recommend that metal "fleas" be added to the capillary tube before the ends are capped. During transport, a magnet can be moved up and down the outside of the capillary tube to facilitate mixing and prevent the formation of clots, which would cause rejection of the sample. It is important to inform the laboratory or respiratory therapy staff of the number of fleas used so the fleas can be accounted for and removed before

the sample is introduced into the blood gas analyzers. Fleas left in the sample may damage the blood gas equipment if allowed to enter the analyzer. Microtainer samples should be mixed by gently rolling the capillary tube to ensure proper mixing of the heparin with the sample, which prevents the formation of small clots leading to rejection of the sample. Promptly transport the specimen to the laboratory for processing and analysis.

Cord Blood

- ▶ The sample may be collected immediately after delivery from the clamped cord, using a heparinized syringe. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

Scalp Sample

- ▶ Samples for scalp pH may be collected anaerobically before delivery in special scalp-sample collection capillaries and transported immediately to the laboratory for analysis. The procedure takes approximately 5 min. Place the patient on her back with her feet in stirrups. The cervix must be dilated at least 3 to 4 cm. A plastic cone is placed in the vagina and fit snugly against the scalp of the fetus. The cone provides access for visualization using an endoscope and to cleanse the site. The site is pierced with a sharp blade. Containment of the blood droplet can be aided by smearing a small amount of silicone cream on the fetal skin site. The blood sample is collected in a thin, heparinized tube. Some hospitals recommend that small metal fleas be added to the scalp tube before the ends are capped. See preceding section on

capillary collection for discussion of fleas.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Apply pressure to the puncture site for at least 5 min in the unanticoagulated patient and for at least 15 min in the case of a patient receiving anticoagulant therapy. Observe/assess puncture site for bleeding or hematoma formation. Apply pressure bandage.
- ▶ Observe/assess the patient for signs or symptoms of respiratory acidosis, such as dyspnea, headache, tachycardia, pallor, diaphoresis, apprehension, drowsiness, coma, hypertension, or disorientation.
- ▶ Teach the patient breathing exercises to assist with the appropriate exchange of oxygen and carbon dioxide.
- ▶ Administer oxygen, if appropriate.
- ▶ Teach the patient how to properly use the incentive spirometer device or mininebulizer if ordered.
- ▶ Observe/assess the patient for signs or symptoms of respiratory alkalosis, such as tachypnea, restlessness, agitation, tetany, numbness, seizures, muscle cramps, dizziness, or tingling fingertips.
- ▶ Instruct the patient to breathe deeply and slowly; performing this type of breathing exercise into a paper bag decreases hyperventilation and quickly helps the patient's breathing return to normal.
- ▶ Observe/assess the patient for signs or symptoms of metabolic acidosis, such as rapid breathing, flushed skin, nausea, vomiting, dysrhythmias, coma, hypotension, hyperventilation, and restlessness.
- ▶ Observe/assess the patient for signs or symptoms of metabolic alkalosis, such as shallow breathing, weakness, dysrhythmias, tetany, hypokalemia, hyperactive reflexes, and excessive vomiting.

- ▶ **Nutritional Considerations:** Abnormal blood gas values may be associated with diseases of the respiratory system. Malnutrition is commonly seen in patients with severe respiratory disease for reasons including fatigue, lack of appetite, and gastrointestinal distress. Research has estimated that the daily caloric intake required for respiration of patients with COPD is 10 times higher than that of normal individuals. Inadequate nutrition can result in hypophosphatemia, especially in the respirator-dependent patient. During periods of starvation, phosphorus leaves the intracellular space and moves outside the tissue, resulting in dangerously decreased phosphorus levels. Adequate intake of vitamins A and C is also important to prevent pulmonary infection and to decrease the extent of lung tissue damage. The importance of following the prescribed diet should be stressed to the patient and/or caregiver.
- ▶ Water balance needs to be closely monitored in COPD patients. Fluid retention can lead to pulmonary edema.
 - ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient cough and breathing techniques with splinting to improve ventilation.
- ▶ Teach the patient to pace activities to avoid becoming short of breath.

- ▶ Teach the patient the appropriate use of oxygen therapy.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that additional diagnostic studies may need to be completed to identify the underlying cause of the altered blood gas results
- ▶ States understanding that oxygen therapy can improve blood oxygen levels

Skills

- ▶ Demonstrates proficiency in the self-administration of medication to treat the underlying cause of the altered blood gas results
- ▶ Demonstrates the ability to position himself or herself in an upright position to improve oxygenation

Attitude

- ▶ Complies with the request to change position every 2 hr to decrease the risk of atelectasis
- ▶ Complies with the request to use ordered oxygen to support and improve oxygenation

RELATED MONOGRAPHS:

- ▶ Related tests include α_1 -AT, anion gap, arterial/alveolar oxygen ratio, biopsy lung, bronchoscopy, carboxyhemoglobin, chest x-ray, chloride sweat, CBC hemoglobin, CBC WBC and diff, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, electrolytes, gram stain, IgE, lactic acid, lung perfusion scan, lung ventilation scan, MRI venography, osmolality, phosphorus, plethysmography, pleural fluid analysis, pulse oximetry, PFT, and TB skin tests.
- ▶ Refer to the Cardiovascular, Genitourinary, and Respiratory systems tables at the end of the book for related tests by body system.

Blood Groups and Antibodies

B

SYNONYM/ACRONYM: ABO group and Rh typing, blood group antibodies, type and screen, type and crossmatch.

COMMON USE: To identify ABO blood group and Rh type, typically for transfusion purposes.

SPECIMEN: Serum (2 mL) collected in a red-top tube or whole blood (2 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: FDA-approved reagents with glass slides, glass tubes, gel, or automated systems) Compatibility (no clumping or hemolysis).

DESCRIPTION: Blood typing is a series of tests that include the ABO and Rh blood-group system performed to detect surface antigens on red blood cells (RBCs) by an agglutination test and compatibility tests to determine antibodies against these antigens. The major antigens in the ABO system are A and B, although AB and O are also common phenotypes. The patient with A antigens has group A blood; the patient with B antigens has group B blood. The patient with both A and B antigens has group AB blood (universal recipient); the patient with neither A nor B antigens has group O blood (universal donor). Blood group and type is genetically determined. After 6 mo of age, individuals develop serum antibodies that react with A or B antigen absent from their own RBCs. These are called *anti-A* and *anti-B* antibodies.

In ABO blood typing, the patient's RBCs mix with anti-A and anti-B sera, a process known as *forward grouping*. The process then reverses, and the patient's serum mixes with type A and B cells in *reverse grouping*.

Generally, only blood with the same ABO group and Rh type as

the recipient is transfused because the anti-A and anti-B antibodies are strong agglutinins that cause a rapid, complement-mediated destruction of incompatible cells. However, blood donations have decreased nationwide, creating shortages in the available supply. Safe substitutions with blood of a different group and/or Rh type may occur depending on the inventory of available units. Many laboratories require consultation with the requesting health-care provider (HCP) prior to issuing Rh-positive units to an Rh-negative individual.

ABO and Rh testing is also performed as a prenatal screen in pregnant women to identify the risk of hemolytic disease of the newborn. Although most of the anti-A and anti-B activity resides in the immunoglobulin M (IgM) class of immunoglobulins, some activity rests with immunoglobulin G (IgG). Anti-A and anti-B antibodies of the IgG class coat the RBCs without immediately affecting their viability and can readily cross the placenta, resulting in hemolytic disease of the newborn. Individuals with type O blood frequently have more IgG anti-A and anti-B than other people; thus, ABO

hemolytic disease of the newborn will affect infants of type O mothers almost exclusively (unless the newborn is also type O).

Major antigens of the Rh system are D (or Rh_D), C, E, c, and e. Individuals whose RBCs possess D antigen are called Rh-positive; those who lack D antigen are called Rh-negative, no matter what other Rh antigens are present. Individuals who are Rh-negative produce anti-D antibodies when exposed to Rh-positive cells by either transfusions or pregnancy. These anti-D antibodies cross the placenta to the fetus and can cause hemolytic disease of the newborn or transfusion reactions if Rh-positive blood is administered.

The type and screen (T&S) procedure is performed to determine the ABO/Rh and identify any antibodies that may react with transfused blood products. The T&S may take from 30 to 45 min or longer to complete depending on whether unexpected or unusual antibodies are detected. Every unit of product must be crossmatched against the intended recipient's serum and red blood cells for compatibility before transfusion. Knowing the ABO/Rh and antibody status saves time when the patient's sample is crossmatched against units of donated blood products. There are three crossmatch procedures. If no antibodies are identified in the T&S, it is permissible to use either an immediate spin crossmatch or an electronic crossmatch, either of which may take 5 to 10 min to complete. If antibodies are detected, the anti-globulin crossmatch procedure is performed, along with antibody identification testing, or the process is repeated, beginning with the selection of other units for compat-

ibility testing. Typically, specimens for T&S can be held for 72 hr from the time of collection for use in future crossmatch procedures. This time frame may be extended for up to 14 days for patients with a reliably known history of no prior transfusions or pregnancy within the previous 3 months. Donated blood products are tested for ABO type, Rh factor, blood group antibodies, and transmissible infectious diseases to include hepatitis B surface antigen, hepatitis B core antibody, hepatitis C antibody (by the nucleic acid test [NAT]), ALT, HTLV I and II antibody, HIV 1 and 2 antibody, syphilis, West Nile virus (by the nucleic acid test [NAT]), and *Trypanosoma cruzi*.

Febrile nonhemolytic reaction and urticarial/allergic reaction are the two most common types of reactions that occur in blood product transfusions. Many institutions have a policy that provides for premedication with acetaminophen and diphenhydramine to avoid initiation of mild transfusion reactions, where appropriate.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine ABO and Rh compatibility of donor and recipient before transfusion (type and screen or crossmatch).
- Determine anti-D antibody titer of Rh-negative mothers after sensitization by pregnancy with an Rh-positive fetus.
- Determine the need for a micro-dose of immunosuppressive therapy (e.g., with RhoGAM) during the first 12 wk of gestation or a standard dose after 12 wk of gestation for complications such as abortion,

miscarriage, vaginal hemorrhage, ectopic pregnancy, or abdominal trauma.

- Determine Rh blood type and perform antibody screen of prenatal patients on initial visit to determine maternal Rh type and to indicate whether maternal RBCs have been sensitized by any antibodies known to cause hemolytic disease of the newborn, especially anti-D antibody. Rh blood type, antibody screen, and antibody titration (if an antibody has been identified) will be rechecked at 28 wk of gestation and prior to injection of prophylactic standard dose of Rh₀(D) immune globulin RhoGAM IM or Rhophylac IM or IV for Rh-negative mothers. These tests will also be repeated after delivery of an Rh-positive fetus to an Rh-negative mother and prior to injection of prophylactic standard dose of Rh₀(D) immune globulin (if maternal Rh-negative blood has not been previously sensitized with Rh-positive cells resulting in a positive anti-D antibody titer). A postpartum blood sample must be evaluated for fetal-maternal bleed on all Rh-negative mothers to determine the need for additional doses of Rh immune globulin. One in 300 cases will demonstrate hemorrhage greater than 15 mL of blood and require additional Rh₀(D) immune globulin.

- Identify donor ABO and Rh blood type for stored blood.
- Identify maternal and infant ABO and Rh blood types to predict risk of hemolytic disease of the newborn.
- Identify the patient's ABO and Rh blood type, especially before a procedure in which blood loss is a threat or blood replacement may be needed.
- Identify any unusual transfusion related antibodies in the patient's blood, especially before a procedure in which blood replacement may be needed.

POTENTIAL DIAGNOSIS

- **Agglutination is graded from 1+ to 4+ in manual testing systems; with 4+ being the strongest degree of agglutination. Automated testing systems are capable of reporting 1+ to 4+ graded results, or providing images of the tested material so laboratory professionals can interpret the results, or providing computer assisted interpretation of the test results as positive or negative findings.**
- ABO system: A, B, AB, or O specific to person
- Rh system: positive or negative specific to person
- Crossmatching: compatibility between donor and recipient
- Incompatibility indicated by clumping (agglutination) of red blood cells

Group and Type	Incidence (%)	Alternative Transfusion Group and Type of Packed Cell Units in Order of Preference If Patient's Own Group and Type Not Available
O positive	37.4	O negative
O negative	6.6	O positive*
A positive	35.7	A negative, O positive, O negative
A negative	6.3	O negative, A positive, * O positive*
B positive	8.5	B negative, O positive, O negative
B negative	1.5	O negative, B positive, * O positive*
AB positive	3.4	AB negative, A positive, B positive, A negative, B negative, O positive, O negative

Group and Type	Incidence (%)	Alternative Transfusion Group and Type of Packed Cell Units in Order of Preference If Patient's Own Group and Type Not Available
AB negative	0.6	A negative, B negative, O negative, AB positive,* A positive,* B positive,* O positive*
<i>Rh Type</i>		
Rh positive	85–90	
Rh negative	10–15	

*If blood units of exact match to the patient's group and type are not available, a switch in ABO blood group is preferable to a change in Rh type. However, in extreme circumstances, Rh-positive blood can be issued to an Rh-negative recipient. It is very likely that the recipient will develop antibodies as the result of receiving Rh-positive red blood cells. Rh antibodies are highly immunogenic, and, once the antibodies are developed, the recipient can only receive Rh-negative blood for subsequent red blood cell transfusion.

CRITICAL FINDINGS

Note and immediately report to the HCP any signs and symptoms associated with a blood transfusion reaction.

It is essential that critical findings be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Signs and symptoms of blood transfusion reaction range from mildly febrile to anaphylactic and may include chills, dyspnea, fever, headache, nausea, vomiting, palpitations and tachycardia, chest or

back pain, apprehension, flushing, hives, angioedema, diarrhea, hypotension, oliguria, hemoglobinuria, renal failure, sepsis, shock, and jaundice. Complications from disseminated intravascular coagulation (DIC) may also occur.

Possible interventions in mildly febrile reactions include slowing the rate of infusion, then verifying and comparing patient identification, transfusion requisition, and blood bag label. The patient should be monitored closely for further development of signs and symptoms. Administration of epinephrine may be ordered.

Possible interventions in a more severe transfusion reaction may include immediate cessation of infusion, notification of the HCP, keeping the IV line open with saline or lactated Ringer's solution, collection of red- and lavender-top tubes for posttransfusion work-up, collection of urine, monitoring vital signs every 5 min, ordering additional testing if DIC is suspected, maintaining patent airway and blood pressure, and administering mannitol. See Appendix F online at DavisPlus for a more detailed description of transfusion reactions and potential nursing interventions.

INTERFERING FACTORS

- Drugs, including levodopa, methyl-dopa, methyldopate hydrochloride, and cephalexin, may cause a

false-positive result in Rh typing and in antibody screens.

- Recent administration of blood, blood products, dextran, or IV contrast medium causes cellular aggregation resembling agglutination in ABO typing.
- Contrast material such as iodine, barium, and gadolinium may interfere with testing.
- Abnormal proteins, cold agglutinins, and bacteremia may interfere with testing.
- Testing does not detect every antibody and may miss the presence of a weak antibody.
- History of bone marrow transplant, cancer, or leukemia may cause discrepancy in ABO typing.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Injury risk (<i>Related to possible transfusion reaction secondary to protein hypersensitivity; WBC febrile reaction; hemolytic incompatibility</i>)	Fever, chills, rash, itching, decreased blood flow to organs, renal failure	Take vital signs prior to transfusion; take vital signs within 15 min after the transfusion has started and assess for fever and chills; monitor for fever, chills, itching, and rash during transfusion; administer ordered premedication to prevent fever and itching; consider the use of a leukocyte filter; follow standard hospital procedure to ensure a correct match prior to transfusion; immediately stop transfusion if reaction is noted; follow institutional process for assessing for transfusion reaction; collect urine and blood sample for analysis per institutional policy
Gas exchange (<i>Related to insufficient oxygen supply secondary to blood loss</i>)	Decreased activity tolerance; increased shortness of breath with activity; weakness; orthopnea; cyanosis; cough; increased heart rate; weight gain; edema in the lower	Auscultate and trend breath sounds; perform pulse oximetry to monitor oxygenation; administer oxygen as ordered; collaborate with physician to consider intubation and/or mechanical ventilation; place the head of the bed in high Fowler's position;

Problem	Signs & Symptoms	Interventions
	extremities; weakness; increased respiratory rate; use of respiratory accessory muscles	administer diuretics, vasodilators as ordered; administer ordered blood or blood products; monitor HGB/HCT
Cardiac output (<i>Related to inadequate circulating blood supply secondary to blood loss</i>)	Decreased peripheral pulses; decreased urinary output; cool, clammy skin; tachypnea; dyspnea; edema; altered level of consciousness; abnormal heart sounds; crackles in lungs; decreased activity tolerance; weight gain; fatigue; hypoxia	Assess peripheral pulses and capillary refill; monitor blood pressure and check for orthostatic changes; assess respiratory rate, breath sounds, and orthopnea; assess skin color and temperature; assess level of consciousness; monitor urinary output; use pulse oximetry to monitor oxygenation; monitor sodium and potassium levels; monitor HGB/HCT; administer ordered oxygen
Fluid volume (<i>Related to increased circulatory volume secondary to blood transfusion and normal saline IV fluids</i>)	Excess: edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values	Monitor transfusion rate, transfuse according to standards of care; monitor respiratory status with establishment of baseline assessment data; administer ordered diuretic

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of blood type.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and hematopoietic systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent or past procedures, especially blood or blood product transfusion or bone marrow transplantation, that could complicate or interfere with test results.
- ▶ Obtain a list of the patient's current medications including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is

important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ *Make sure a written and informed consent has been signed prior to any transfusion blood products.*

INTRATEST:

Potential Complications:

A transfusion reaction may occur in some patients. A transfusion reaction is also a critical finding. Signs, symptoms, and possible interventions are described in the Critical Findings section.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Although correct patient identification is important for test specimens, it is crucial when blood is collected for type and crossmatch because clerical error is the most frequent cause of life-threatening ABO incompatibility. Therefore, additional requirements are necessary, including the verification of two unique identifiers that could include any two unique patient demographics such as name, date of birth, Social Security number, hospital number, date, or blood bank number on requisition and specimen labels; completing and applying a wristband on the arm with the same information; and placing labels with the same information and blood bank number on blood sample tubes.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site

for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Inform the patient of ABO blood and Rh type, and advise him or her to record the information on a card or other document routinely carried.
- ▶ Inform women who are Rh-negative to inform the HCP of their Rh-negative status if they become pregnant or need a transfusion.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ Verbalizes understanding regarding the risks and benefits of blood transfusion
- ▶ Discusses possible transfusion alternatives other than donor blood

Skills

- ▶ Identifies transfusion reaction symptoms that should be immediately reported
- ▶ States understanding that the purpose of the transfusion is to replace lost circulating blood stores

Attitude

- ▶ Discusses and resolves anxiety related to blood transfusion
- ▶ Voices any religious or cultural objections to the ordered transfusion

RELATED MONOGRAPHS:

Related tests include Coomb's antiglobulin, bilirubin, CBC, CBC hematocrit, CBC hemoglobin, CBC platelet count, CBC RBC count, cold agglutinin, FDP, fecal analysis, GI blood loss scan, haptoglobin, IgA, iron, Kleihauer-Betke, laparoscopy abdominal, Meckel's diverticulum scan, and UA.

- Refer to Appendix F online at DavisPlus for further information regarding laboratory studies used in the investigation of transfusion reactions, findings, and potential nursing interventions associated with types of transfusion reactions.
- Refer to the Immune and Hematopoietic systems tables at the end of the book for related tests by body system.

Blood Pool Imaging

SYNONYM/ACRONYM: Cardiac blood pool scan, ejection fraction study, gated cardiac scan, radionuclide ventriculogram, wall motion study, MUGA.

COMMON USE: To evaluate cardiac function after a myocardial infarction.

AREA OF APPLICATION: Heart.

CONTRAST: Intravenous radioactive material.

DESCRIPTION: Multigated blood pool imaging (MUGA; also known as *cardiac blood pool scan*) is used to diagnose cardiac abnormalities involving the left ventricle and myocardial wall abnormalities by imaging the blood within the cardiac chamber rather than the myocardium. The ventricular blood pool can be imaged during the initial transit of a peripherally injected, intravenous bolus of radionuclide (first-pass technique) or when the radionuclide has reached equilibrium concentration. The patient's electrocardiogram (ECG) is synchronized to the gamma camera imager and computer and therefore termed "gated." For multigated studies, technetium-99m (Tc-99m) pertechnetate is injected after an injection of pyrophosphate,

allowing the labeling of circulating red blood cells; Tc-99m sulfur colloid is used for first-pass studies. Studies detect abnormalities in heart wall motion at rest or with exercise, ejection fraction, ventricular dilation, stroke volume, and cardiac output. The MUGA procedure, performed with the heart in motion, is used to obtain multiple images of the heart in contraction and relaxation during an R-to-R cardiac cycle. The resulting images can be displayed in a cinematic mode to visualize cardiac function. Repetitive data acquisitions are possible during graded levels of exercise, usually a bicycle ergometer or handgrip, to assess ventricular functional response to exercise.

After the administration of sublingual nitroglycerin, the

MUGA scan can evaluate the effectiveness of the drug on ventricular function. Heart shunt imaging is done in conjunction with a resting MUGA scan to obtain ejection fraction and assess regional wall motion. First-pass cardiac flow study is done to study heart chamber disorders, including left-to-right and right-to-left shunts, determine both right and left ventricular ejection fractions, and assess blood flow through the great vessels. The study uses a jugular or antecubital vein injection of the radionuclide.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients with anginal pain at rest or in patients with severe atherosclerotic coronary vessels; dipyridamole testing is not performed in these circumstances.
-  Chemical stress with vasodilators in patients having asthma (*because bronchospasm can occur*).

INDICATIONS

- Aid in the diagnosis of myocardial infarction
- Aid in the diagnosis of true or false ventricular aneurysms
- Aid in the diagnosis of valvular heart disease and determining the optimal time for valve replacement surgery
- Detect left-to-right shunts and determine pulmonary-to-systemic blood flow ratios, especially in children

- Determine cardiomyopathy
- Determine drug cardiotoxicity to stop therapy before development of congestive heart failure
- Determine ischemic coronary artery disease
- Differentiate between chronic obstructive pulmonary disease and left ventricular failure
- Evaluate ventricular size, function, and wall motion after an acute episode or in chronic heart disease
- Quantitate cardiac output by calculating global or regional ejection fraction

POTENTIAL DIAGNOSIS

Normal findings in

- Normal wall motion, ejection fraction (55% to 65%), coronary blood flow, ventricular size and function, and symmetry in contractions of the left ventricle

Abnormal findings in

- Abnormal wall motion (akinesia or dyskinesia)
- Cardiac hypertrophy
- Cardiac ischemia
- Enlarged left ventricle
- Infarcted areas are akinetic
- Ischemic areas are hypokinetic
- Myocardial infarction

CRITICAL FINDINGS

- Myocardial infarction

It is essential that critical findings be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. The notification processes will vary among facilities. Upon receipt of the critical finding the information should be read back to the caller to verify accuracy. Most policies require

immediate notification of the primary HCP, hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical finding, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS: N/A

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images.

Other considerations

- Conditions such as chest wall trauma, cardiac trauma, angina that is difficult to control, significant cardiac arrhythmias, or a recent cardioversion procedure may affect test results.
- Atrial fibrillation and extrasystoles invalidate the procedure.
- Suboptimal cardiac stress or patient exhaustion, preventing maximum heart rate testing, will affect results when the procedure is done in conjunction with exercise testing.
- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than neces-

sary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the pumping action of the heart.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, radionuclides, or medications used in the procedure.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of

discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure and takes approximately 60 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct the patient to wear walking shoes for the treadmill or bicycle exercise. Emphasize to the patient the importance of reporting fatigue, pain, or shortness of breath.
- ▶ Instruct the patient to remove external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to fast and restrict fluids for 4 hr prior to the procedure. Instruct the patient to withhold medications for 24 hr before the test as ordered by the HCP. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injection of radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**), hematoma (**related to blood leakage**

into the tissue following needle insertion), infection (**that might occur if bacteria from the skin surface is introduced at the puncture site**), or nerve injury (**that might occur if the needle strikes a nerve**).

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary and medication restrictions.
- ▶ Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ The patient is placed at rest in the supine position on the scanning table.
- ▶ Expose the chest and attach the ECG leads. Record baseline readings.
- ▶ IV radionuclide is administered and the heart is scanned with images taken in various positions over the entire cardiac cycle.
- ▶ When the scan is to be done under exercise conditions, the patient is assisted onto the treadmill or bicycle ergometer and is exercised to a calculated 80% to 85% of the maximum heart rate as determined by the protocol selected. Images are done at each exercise level and begun immediately after injection of the radionuclide.
- ▶ If nitroglycerin is given, an HCP assessing the baseline MUGA scan injects the medication. Additional

- scans are repeated until blood pressure reaches the desired level.
- ▶ Patients who cannot exercise are given dipyridamole before the radionuclide is injected.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter site for bleeding, hematoma formation, or inflammation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
 - ▶ Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
 - ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
 - ▶ Evaluate the patient's vital signs. Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by HCP. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary among facilities.
 - ▶ Instruct the patient to resume usual dietary, medication, and activity, as directed by the HCP.
 - ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
 - ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
 - ▶ Monitor ECG tracings and compare with baseline readings until stable.
 - ▶ Observe/assess the needle/catheter site for bleeding, hematoma formation, or inflammation.
- ▶ Instruct the patient in the care and assessment of the injection site.
 - ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
 - ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
 - ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
 - ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated low-density lipoprotein [LDL] cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides are also elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a "Mediterranean"-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils

(e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.

- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- ▶ Recognize anxiety related to test results, and be supportive of perceived

loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate and determine the need for a change in therapy or progression of the disease process. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BNP, calcium, ionized calcium, cholesterol (total, HDL, and LDL), CRP, CT cardiac scoring, CK and isoenzymes, culture viral, echocardiography, echocardiography transesophageal, ECG, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, pericardial fluid analysis, PET heart scan, potassium, triglycerides, and troponin.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Bone Mineral Densitometry

SYNONYM/ACRONYM: DEXA, DXA, SXA, QCT, RA, ultrasound densitometry.

Dual-energy x-ray absorptiometry (DEXA, DXA): Two x-rays of different energy levels measure bone mineral density and predict risk of fracture.

Single-energy x-ray absorptiometry (SXA): A single-energy x-ray measures bone density at peripheral sites.

Quantitative computed tomography (QCT): QCT is used to examine the lumbar vertebrae. It measures trabecular and cortical bone density. Results are

compared to a known standard. This test is the most expensive and involves the highest radiation dose of all techniques.

Radiographic absorptiometry (RA): A standard x-ray of the hand. Results are compared to a known standard.

Ultrasound densitometry: Studies bone mineral content in peripheral densitometry sites such as the heel or wrist. It is not as precise as x-ray techniques but is less expensive than other techniques.

COMMON USE: To evaluate bone density related to osteoporosis.

AREA OF APPLICATION: Lumbar spine, heel, hip, wrist, whole body.

CONTRAST: None.

DESCRIPTION: Bone mineral density (BMD) can be measured at any of several body sites, including the spine, hip, wrist, and heel.

Machines to measure BMD include computed tomography (CT), radiographic absorptiometry, ultrasound, SXA, and most commonly, DEXA. The radiation exposure from SXA and DEXA machines is approximately one-tenth that of a standard chest x-ray.

Osteoporosis is a condition characterized by low BMD, which results in increased risk of fracture. The National Osteoporosis Foundation estimates that 4 to 6 million postmenopausal women in the United States have osteoporosis, and an additional 13 to 17 million (30% to 50%) have low bone density at the hip. It is estimated that one of every two women will experience a fracture as a result of low bone mineral content in her lifetime. The measurement of BMD gives the best indication of risk for a fracture. The lower the BMD, the greater is the risk of fracture. The most common fractures are those of the hip, vertebrae, and distal forearm. Bone mineral loss is a disease of the entire skeleton and is not restricted to the areas listed. The

effect of the fractures has a wide range, from complete recovery to chronic pain, disability, and possible death.

The BMD values measured by the various techniques cannot be directly compared. Therefore, they are stated in terms of standard deviation (SD) units. The patient's T-score is the number of SD units above or below the average BMD in young adults. A Z-score is the number of SD units above or below the average value for a person of the same age as the measured patient. Since bone loss occurs naturally as part of the aging process, using a patient's Z-score in comparison to a person of the same age could be misleading, especially in the early development of osteoporosis. The World Health Organization has defined normal bone density as being within (above or below) 1 SD of the mean for young adults. Low bone density is defined as density below 1 SD and 2.5 SD the mean for young adults, bone density 2.5 SD or more below the mean for young adults is indicative of osteoporosis (osteopenia), and bone density more than 2.5 SD below the mean for young adults is defined as severe

(established) osteoporosis. The baseline age for young adults is approximately 30 years of age. For most BMD readings, 1 SD is equivalent to 10% to 12% of the average young-normal BMD value. A T-score of -2.5 is therefore equivalent to a bone mineral loss of 30% when compared to a young adult.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Determine the mineral content of bone
- Determine a possible cause of amenorrhea
- Establish a diagnosis of osteoporosis
- Estimate the actual fracture risk compared to young adults
- Evaluate bone demineralization associated with chronic renal failure
- Evaluate bone demineralization associated with immobilization
- Monitor changes in BMD due to medical problems or therapeutic intervention
- Predict future fracture risk

POTENTIAL DIAGNOSIS

Normal findings in

- Normal bone mass with T-score value not less than -1 .

Abnormal findings in

- Osteoporosis is defined as T-score value less than -2.5 .
- Low bone mass or osteopenia has T-scores from -1 to -2.5 .

- Fracture risk increases as BMD declines from young-normal levels (low T-scores).
- Low Z-scores in older adults can be misleading because low BMD is very common.
- Z-scores estimate fracture risk compared to others of the same age (versus young-normal adults).

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- BMD test results may be lower in individuals receiving corticosteroid therapy; ideally BMD testing should be performed before a patient is placed on a regimen of chronic steroid therapy to obtain a valid baseline.

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects within the examination field (e.g., jewelry, earrings, and/or dental amalgams), which may inhibit organ visualization and can produce unclear images.

Other considerations

- The use of anticonvulsant drugs, cytotoxic drugs, tamoxifen, glucocorticoids, lithium, or heparin, as well as increased alcohol intake, increased aluminum levels, excessive thyroxin, renal dialysis, or smoking, may affect the test results by either increasing or decreasing the bone mineral content.
 - Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Pediatric & Geriatric Imaging**
Children and geriatric patients are at

risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation over-exposure can result from frequent x-ray or radionuclide procedures. Personnel in the room with the patient should stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their radiation exposure level.

Other considerations as a result of altered BMD, not the BMD testing process

- Vertebral fractures may cause complications including back pain, height loss, and kyphosis.
- Limited activity, including difficulty bending and reaching, may result.
- Patient may have poor self-esteem resulting from the cosmetic effects of kyphosis.
- Potential restricted lung function may result from fractures.
- Fractures may alter abdominal anatomy, resulting in constipation, pain, distention, and diminished appetite.
- Potential for a restricted lifestyle may result in depression and other psychological symptoms.
- Possible increased dependency on family for basic care may occur.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing bone density.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, iodine, seafood, contrast medium, anesthetics, or dyes.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is usually performed in a radiology department by a HCP, and staff, specializing in this procedure and takes approximately 60 min.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided. Patient's clothing may not need to be removed unless it contains metal that would interfere with the test.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- ▶ Provide contact information, if desired, for the National Osteoporosis Foundation (www.nof.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms, previous BMD values, and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALP, antibodies anticyclic citrullinated peptide, ANA, arthrogram, arthroscopy, biopsy bone, bone scan, calcium, CRP, collagen cross-linked telopeptides, CT pelvis, CT spine, ESR, MRI musculoskeletal, MRI pelvis, osteocalcin, PTH, phosphorus, radiography bone, RF, synovial fluid analysis, and vitamin D.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Bone Scan

SYNONYM/ACRONYM: Bone imaging, radionuclide bone scan, bone scintigraphy, whole-body bone scan.

COMMON USE: To assist in diagnosing bone disease such as cancer or other degenerative bone disorders.

AREA OF APPLICATION: Bone/skeleton.

CONTRAST: Intravenous radioactive material (diphosphonate compounds), usually combined with technetium-99m.

DESCRIPTION: This nuclear medicine scan assists in diagnosing and determining the extent of primary and metastatic bone disease and bone trauma and monitors the progression of degenerative disorders. Abnormalities are identified by scanning 1 to 3 hr after the intravenous injection of a radionuclide such as technetium-99m methylene diphosphonate. Areas of increased uptake and activity on the bone scan represent abnormalities unless they occur in normal areas of increased activity, such as the sternum, sacroiliac, clavicle, and scapular joints in adults, and growth centers and cranial sutures in children. The radionuclide mimics calcium physiologically and therefore localizes in bone with an intensity proportional to the degree of metabolic activity. Gallium, magnetic resonance imaging (MRI), or white blood cell scanning can follow a bone scan to obtain a more sensitive study if acute inflammatory conditions such as osteomyelitis or septic arthritis are suspected. In addition, bone scan can detect fractures in patients who continue to have pain even though x-rays have proved negative. A gamma camera detects the radiation emitted from the injected radioactive material. Whole-body or representative images of the skeletal system can be obtained. Single-photon emission computed tomography (SPECT) has significantly improved the resolution and accuracy of bone scanning and may or may not be included as part of the examination. SPECT enables images to be recorded from multiple angles around the body and

reconstructed by a computer to produce images or “slices” representing the area of interest at different levels.

This procedure is contraindicated for

Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of benign tumors or cysts
- Aid in the diagnosis of metabolic bone diseases
- Aid in the diagnosis of osteomyelitis
- Aid in the diagnosis of primary malignant bone tumors (e.g., osteogenic sarcoma, chondrosarcoma, Ewing’s sarcoma, metastatic malignant tumors)
- Aid in the detection of traumatic or stress fractures
- Assess degenerative joint changes or acute septic arthritis
- Assess suspected child abuse
- Confirm temporomandibular joint derangement
- Detect Legg-Calvé-Perthes disease
- Determine the cause of unexplained bone or joint pain
- Evaluate the healing process following fracture, especially if an underlying bone disease is present
- Evaluate prosthetic joints for infection, loosening, dislocation, or breakage
- Evaluate tumor response to radiation or chemotherapy
- Identify appropriate site for bone biopsy, lesion excision, or debridement

POTENTIAL DIAGNOSIS

Normal findings in

- No abnormalities, as indicated by homogeneous and symmetric distribution of the radionuclide throughout all skeletal structures

Abnormal findings in

- Bone necrosis
- Degenerative arthritis
- Fracture
- Legg-Calvé-Perthes disease
- Metastatic bone neoplasm
- Osteomyelitis
- Paget's disease
- Primary metastatic bone tumors
- Renal osteodystrophy
- Rheumatoid arthritis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects within the examination field (e.g., jewelry, earrings, and/or dental amalgams), which may inhibit organ visualization and can produce unclear images.
- Retained barium from a previous radiological procedure may affect the image.
- A distended bladder may obscure pelvic detail.
- Other nuclear scans done within the previous 24 to 48 hr may alter image.

Other considerations

- The existence of multiple myeloma or thyroid cancer can result in a false-negative scan for bone abnormalities.
- Improper injection of the radionuclide may allow the tracer to seep

deep into the muscle tissue, producing erroneous hot spots.

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in identification of bone disease before it can be detected with plain x-ray images.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of results of the patient's musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.

- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure, and takes approximately 30 to 60 min. **Pediatric Considerations** Preparing children for a bone scan depends on the age of the child. Encourage parents to be truthful about what the child may experience during the procedure (e.g., there may be a pinch or minor discomfort when the IV needle is inserted) and to use words that they know their child will understand. Toddlers and preschool-age children have a very short attention span, so the best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with the child during the procedure. Explain the importance of remaining still while the images are taken.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Instruct the patient to remove jewelry and other metallic objects in the area to be examined.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injection of radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**), hematoma (**related to blood leakage into the tissue following needle insertion**), infection (**that might occur if bacteria from the skin surface is introduced at the puncture site**), or nerve injury (**that might occur if the needle strikes a nerve**).

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure as a full bladder may obscure pelvic bones, and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.

- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Administer sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- ▶ IV radionuclide is administered and images are taken immediately to assess blood flow to the bones.
- ▶ After a delay of 2 to 3 hr to allow the radionuclide to be taken up by the bones, multiple images are obtained over the complete skeleton. Delayed views may be taken up to 24 hr after the injection.
- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ The patient may be imaged by single-photon emission computed tomography (SPECT) techniques to further clarify areas of suspicious radionuclide localization.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Instruct the patient to resume medication and activity as directed by the HCP.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not

breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.

- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after the gloves are removed.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org) or for the Arthritis Foundation (www.arthritis.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antibodies, anticyclic citrullinated peptide, ANA, arthroscopy, BMD, calcium, CRP, collagen cross-linked telopeptide, CT pelvis, CT spine, culture blood, ESR, MRI musculoskeletal, MRI pelvis, osteocalcin, radiography bone, RF, synovial fluid analysis, and white blood cell scan.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Bronchoscopy

SYNONYM/ACRONYM: Flexible bronchoscopy.

COMMON USE: To visualize and assess bronchial structure for disease such as cancer and infection.

AREA OF APPLICATION: Bronchial tree, larynx, trachea.

CONTRAST: None.

DESCRIPTION: This procedure provides direct visualization of the larynx, trachea, and bronchial tree by means of either a rigid or a flexible bronchoscope. A fiberoptic bronchoscope with a light incorporated is guided into the tracheobronchial tree. A local anesthetic may be used to allow the scope to be inserted through the mouth or nose into the trachea and into the bronchi. The patient must breathe during insertion and with the scope in place. The purpose of the procedure is both diagnostic and therapeutic.

The rigid bronchoscope allows visualization of the larger airways, including the lobar, segmental, and subsegmental bronchi, while maintaining effective gas exchange. Rigid bronchoscopy is preferred when large volumes of blood or secretions need to be aspirated, foreign bodies are to be removed, large-sized biopsy specimens are to be obtained, and for most bronchoscopies in children. The flexible fiberoptic bronchoscope has a smaller lumen that is designed to allow for visualization of all segments of the bronchial tree. The accessory lumen of the bronchoscope is used for tissue biopsy, bronchial washings, instillation of anesthetic agents and medications, and to obtain specimens with brushes for cytological examination. In general, fiber-optic

bronchoscopy is less traumatic to the surrounding tissues than the larger rigid bronchoscopes. Fiberoptic bronchoscopy is performed under local anesthesia; patient tolerance is better for fiber-optic bronchoscopy than for rigid bronchoscopy.

This procedure is contraindicated for

-  Patients with bleeding disorders, especially those associated with uremia and cytotoxic chemotherapy.
-  Patients with pulmonary hypertension.
-  Patients with cardiac conditions or dysrhythmias.
-  Patients with disorders that limit extension of the neck.
-  Patients with severe obstructive tracheal conditions.
-  Patients with or having the potential for respiratory failure;

(introduction of the bronchoscope alone may cause a 10 to 20 mm Hg drop in Pao₂)

INDICATIONS

- Detect end-stage bronchogenic cancer
- Detect lung infections and inflammation
- Determine etiology of persistent cough, hemoptysis, hoarseness, unexplained chest x-ray

abnormalities, and/or abnormal cytological findings in sputum

- Determine extent of smoke-inhalation or other traumatic injury
- Evaluate airway patency; aspirate deep or retained secretions
- Evaluate endotracheal tube placement or possible adverse sequelae to tube placement
- Evaluate possible airway obstruction in patients with known or suspected sleep apnea
- Evaluate respiratory distress and tachypnea in an infant to rule out tracheoesophageal fistula or other congenital anomaly
- Identify bleeding sites and remove clots within the tracheobronchial tree
- Identify hemorrhagic and inflammatory changes in Kaposi's sarcoma
- Intubate patients with cervical spine injuries or massive upper airway edema
- Remove foreign body
- Treat lung cancer through instillation of chemotherapeutic agents, implantation of radioisotopes, or laser palliative therapy

POTENTIAL DIAGNOSIS

Normal findings in

- Normal larynx, trachea, bronchi, bronchioles, and alveoli

Abnormal findings in

- Abscess
- Bronchial diverticulum
- Bronchial stenosis
- Bronchogenic cancer
- Coccidioidomycosis, histoplasmosis, blastomycosis, phycomycosis
- Foreign bodies
- Inflammation
- Interstitial pulmonary disease
- Opportunistic lung infections (e.g., pneumocystitis, nocardia, cytomegalovirus)
- Strictures
- Tuberculosis
- Tumors

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects within the examination field (e.g., jewelry, earrings, and/or dental amalgams), which may inhibit organ visualization and can produce unclear images.

Other considerations

- Hypoxemic or hypercapnic states require continuous oxygen administration.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assess the lungs and respiratory system.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, sedatives, or anesthetics.
- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results. Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Instruct that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Explain that a sedative and/or analgesia may be administered to promote relaxation and reduce discomfort prior to the bronchoscopy. Atropine is usually given before bronchoscopy examinations to reduce bronchial secretions and prevent vagally induced bradycardia. Meperidine (Demerol) or morphine may be given as a sedative. Lidocaine is sprayed in the patient's throat to reduce discomfort caused by the presence of the tube. Inform the patient that the procedure is performed in a gastrointestinal laboratory or radiology department, under sterile conditions, by a health-care provider (HCP) specializing in this procedure. The procedure usually takes about 30 to 60 min to complete.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, antibiotics, anesthetics, analgesics, sedatives, or emergency medications.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting

guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Complications from the procedure are rare but may include infection (**related to the use of an endoscope**), hypoxemia, pneumothorax, or bleeding, (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**).

Establishing an IV site is an invasive procedure. Complications are rare but do include risk for bleeding from the puncture site (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**), hematoma (**related to blood leakage into the tissue following needle insertion**), infection (**that might occur if bacteria from the skin surface is introduced at the puncture site**), or nerve injury (**that might occur if the needle strikes a nerve**).

- ▶ Ensure that the patient has complied with food, fluid, and medication restrictions for 8 hr prior to the procedure.
- ▶ Ensure that the patient has removed dentures, jewelry, and external metallic objects in the area to be examined prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.

- ▶ Instruct the patient to void prior to the procedure and change into the gown, robe, and foot coverings provided.
- ▶ Avoid using morphine sulfate in those with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location, especially right or left lung.
- ▶ Assist the patient to a comfortable position, and direct the patient to breathe normally during the beginning of the general anesthesia. Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- ▶ Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, antibiotics, anesthetics, analgesics, sedatives, or emergency medications.

Rigid Bronchoscopy

- ▶ The patient is placed in the supine position and a general anesthetic is administered. The patient's neck is hyperextended, and the lightly lubricated bronchoscope is inserted orally and passed through the glottis. The patient's head is turned or repositioned to aid visualization of various segments.
- ▶ After inspection, the bronchial brush, suction catheter, biopsy forceps, laser, and electrocautery devices are introduced to obtain specimens for cytological or microbiological study or for therapeutic procedures.
- ▶ If a bronchial washing is performed, small amounts of solution are instilled into the airways and removed.
- ▶ After the procedure, the bronchoscope is removed and the patient is placed in

a side-lying position with the head slightly elevated to promote recovery.

Fiberoptic Bronchoscopy

- ▶ Provide mouth care to reduce oral bacterial flora.
- ▶ The patient is placed in a sitting position while the tongue and oropharynx are sprayed or swabbed with local anesthetic. Provide an emesis basin for the increased saliva and encourage the patient to spit out the saliva because the gag reflex may be impaired. When loss of sensation is adequate, the patient is placed in a supine or side-lying position. The fiberoptic scope can be introduced through the nose, the mouth, an endotracheal tube, a tracheostomy tube, or a rigid bronchoscope. Most common insertion is through the nose. Patients with copious secretions or massive hemoptysis, or in whom airway complications are more likely, may be intubated before the bronchoscopy. Additional local anesthetic is applied through the scope as it approaches the vocal cords and the carina, eliminating reflexes in these sensitive areas. The fiberoptic approach allows visualization of airway segments without having to move the patient's head through various positions.
- ▶ After visual inspection of the lungs, tissue samples are collected from suspicious sites by bronchial brush or biopsy forceps to be used for cytological and microbiological studies.
- ▶ After the procedure, the bronchoscope is removed. Patients who had local anesthesia are placed in a semi-Fowler's position to recover.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place tissue samples in properly labeled specimen containers containing formalin solution, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature changes. Protocols may vary among facilities.
- ▶ Emergency resuscitation equipment should be readily available if the vocal cords become spastic after intubation.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breathing sounds over the affected area. Immediately report symptoms to the appropriate HCP.
- ▶ Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.
- ▶ Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.
- ▶ Observe the patient's sputum for blood if a biopsy was taken, because large amounts of blood may indicate the development of a problem; a small amount of streaking is expected. Evaluate the patient for signs of bleeding such as tachycardia, hypotension, or restlessness.
- ▶ Assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy even if signs and symptoms disappear before completion of therapy.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Instruct the patient to use lozenges or gargle for throat discomfort. Inform the patient of smoking cessation programs as appropriate. Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons, including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C is also important to prevent pulmonary infection and to decrease the extent of lung tissue damage. The importance of following the prescribed diet should be stressed to the patient/caregiver. Educate the patient regarding access to counseling services, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include arterial/alveolar oxygen ratio, antibodies, anti-glomerular basement membrane, biopsy lung, blood gases, chest x-ray, complete blood count, CT thorax, culture and smear mycobacteria, culture sputum, culture viral, cytology sputum, Gram stain, lung perfusion scan, lung ventilation scan, MRI chest, mediastinoscopy, and pulse oximetry.
- ▶ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

B-Type Natriuretic Peptide and Pro-B-Type Natriuretic Peptide

SYNONYM/ACRONYM: BNP and proBNP.

COMMON USE: To assist in diagnosing congestive heart failure.

SPECIMEN: Plasma (1 mL) collected in a plastic, lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Chemiluminescent immunoassay for BNP; electrochemiluminescent immunoassay for proBNP)

BNP	Conventional Units	SI Units (Conventional Units × 1)
Male & Female	Less than 100 pg/mL	Less than 100 ng/L
proBNP (N-terminal)		
0–74 yr	Less than 125 pg/mL	Less than 125 ng/mL
Greater than 75 yr	Less than 449 pg/mL	Less than 449 ng/mL

BNP levels are increased in elderly adults.

DESCRIPTION: The peptides B-type natriuretic peptide (BNP) and atrial natriuretic peptide (ANP) are antagonists of the renin-angiotensin-aldosterone system, which assist in the regulation of electrolytes, fluid balance, and blood pressure. BNP, proBNP, and ANP are useful markers in the diagnosis of congestive heart failure (CHF). BNP or brain natriuretic peptide, first isolated in the brain of pigs, is a neurohormone synthesized primarily in the ventricles of the human heart in response to increases in ventricular pressure and volume. Circulating levels of BNP and proBNP increase in proportion to the severity of heart failure. A rapid BNP point-of-care immunoassay may be performed, in which a venous blood sample is collected, placed on a strip, and inserted into a device that measures BNP. Results are completed in 10 to 15 min.

This procedure is contraindicated for

-  Patients receiving Nesiritide. Nesiritide (Natrecor) is a recombinant form of BNP that may be given therapeutically by IV to patients in acutely decompensated heart failure; with some assays, BNP levels may be transiently and significantly elevated at the time of administration and must be interpreted with caution. The testing laboratory should be consulted to verify whether test measurements are affected by Natrecor.

INDICATIONS

- Assist in determining the prognosis and therapy of patients with heart failure
- Assist in the diagnosis of heart failure
- Assist in differentiating heart failure from pulmonary disease
- Cost-effective screen for left ventricular dysfunction; positive findings would point to the need for echocardiography and further assessment

POTENTIAL DIAGNOSIS**Increased in**

BNP is secreted in response to increased hemodynamic load caused by physiological stimuli, as with ventricular stretch or endocrine stimuli from the aldosterone/renin system.

- Cardiac inflammation (myocarditis, cardiac allograft rejection)
- Cirrhosis
- Cushing's syndrome
- Heart failure

- Kawasaki's disease
- Left ventricular hypertrophy
- Myocardial infarction
- Primary hyperaldosteronism
- Primary pulmonary hypertension
- Renal failure
- Ventricular dysfunction

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE**Potential Nursing Problems:**

Problem	Signs & Symptoms	Interventions
Gas exchange <i>(Related to altered alveolar and capillary exchange secondary to fluid in the alveoli)</i>	Decreased activity tolerance; increased shortness of breath with activity; weakness; orthopnea; cyanosis; cough; increased heart rate; weight gain; edema in the lower extremities; weakness; increased respiratory rate; use of respiratory accessory muscles	Auscultate and trend breath sounds; perform pulse oximetry to monitor oxygenation; administer oxygen as ordered; collaborate with physician to consider intubation and/or mechanical ventilation; place the head of the bed in high Fowler's position; administer diuretics, vasodilators as ordered; monitor potassium levels
Tissue perfusion <i>(Related to compromised cardiac contractility; interrupted blood flow)</i>	Hypotension; dizziness; cool extremities; capillary refill greater than 3 sec; weak pedal pulses; altered level of consciousness	Monitor blood pressure; assess for dizziness; check skin temperature for warmth; assess capillary refill; assess pedal pulses; monitor level of consciousness; administer prescribed vasodilators and inotropic drugs

Problem	Signs & Symptoms	Interventions
Cardiac output <i>(Related to increased preload; increased afterload; impaired cardiac contractility; cardiac muscle disease; altered cardiac conduction)</i>	Decreased peripheral pulses; decreased urinary output; cool, clammy skin; tachypnea; dyspnea; edema; altered level of consciousness; abnormal heart sounds; crackles in lungs; decreased activity tolerance; weight gain; fatigue; hypoxia	Assess peripheral pulses and capillary refill; monitor blood pressure and check for orthostatic changes; assess respiratory rate, breath sounds, and orthopnea; assess skin color and temperature; assess level of consciousness; monitor urinary output; use pulse oximetry to monitor oxygenation; monitor sodium and potassium levels; monitor BNP levels; administer ordered angiotensin-converting enzyme (ACE) inhibitors, beta blockers, diuretics, aldosterone antagonists, and vasodilators; provide oxygen administration
Fluid volume <i>(Related to altered cardiac output)</i>	Overload: edema; shortness of breath; increased weight; ascites; rales; rhonchi; diluted laboratory values; increased blood pressure; positive Jugular Venous Distention (JVD); orthopnea; cough; restlessness; tachycardia; pulmonary congestion with x-ray; restlessness	Daily weight with monitoring of trends; fluid limit as appropriate; assess for peripheral edema; assess for adventitious lung sounds such as crackles; monitor blood pressure and heart rate; assess for Jugular Venous Distention (JVD); monitor intake versus output; administer prescribed diuretics; restrict sodium intake; order low sodium diet; monitor laboratory values that reflect alterations in fluid status; manage underlying cause of fluid alteration

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing congestive heart failure.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
 - ▶ **Treatment Considerations for CHF:** Recognize anxiety related to test results, and ensure that the patient (if not currently taking) is placed on an ACE inhibitor, β blocker, and diuretic, and is monitored with daily weight measurement. Discuss risk factors. Teach the patient to safely administer ordered oxygen, as appropriate.
 - ▶ **Nutritional Considerations:** Instruct patients to consume a variety of foods within the basic food groups, eat foods high in potassium when taking diuretics, eat a diet high in fiber (25 to 35 g/day), maintain a healthy weight, be physically active, limit salt intake to 2,000 mg/day, limit alcohol intake, and be a nonsmoker.
 - ▶ **Nutritional Considerations:** Foods high in potassium include fruits such as bananas, strawberries, oranges; cantaloupes; green leafy vegetables such as spinach and broccoli; dried fruits such as dates, prunes, and raisins; legumes such as peas and pinto beans; nuts and whole grains.
 - ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.
- Patient Education:**
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Explain to the patient and family the importance of reporting life-threatening changes such as cool extremities, pallor, and diaphoresis to HCP immediately
- ▶ Ensure family understands to report any changes in mental status such as confusion.

Expected Patient Outcomes:**Knowledge**

- ▶ Recites the importance of limiting fluids to decrease cardiac stress
- ▶ Describes the purpose of taking the prescribed diuretic

Skills

- ▶ Accurately describes strategies to limit fluid intake and decrease cardiac stress

- ▶ Accurately demonstrates how to keep an accurate intake and output

Attitude

- ▶ Compliant with taking all medications as prescribed to support cardiac health
- ▶ Adheres to treatment recommendations that can help to prevent a potentially life-threatening situation

RELATED MONOGRAPHS:

- ▶ Related tests include angiography pulmonary, AST, ANF, calcium and ionized calcium, CRP, CK and isoenzymes, CT scoring, echocardiography, glucose, homocysteine, Holter monitor, LDH and isoenzymes, magnesium, MRI chest, MI scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, and troponin.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Calcitonin and Calcitonin Stimulation Tests

SYNONYM/ACRONYM: Thyrocalcitonin, hCT.

COMMON USE: To diagnose and monitor the effectiveness of treatment for medullary thyroid cancer.

SPECIMEN: Serum (3 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum in a plastic transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Chemiluminescent immunoassay)

C

Procedure	Medication Administered	Recommended Collection Times
Calcium and pentagastrin stimulation	Calcium, 2 mg/kg IV for 1 min, followed by pentagastrin 0.5 mcg/kg	4 calcitonin levels—baseline immediately before bolus; and 1 min, 2 min, and 5 min postbolus
Calcium stimulation	Calcium, 2 mg/kg IV for 1 min or 2.4 mg/kg IV push	4 calcitonin levels—baseline immediately before bolus; and 1 min, 2 min, and 5 min postbolus
Pentagastrin stimulation	Pentagastrin 0.5 mcg/kg	4 calcitonin levels—baseline immediately before bolus; and 1 min, 2 min, and 5 min postbolus

IV = intravenous.

	Conventional Units	SI Units (Conventional Units × 1)
<i>Calcitonin Baseline</i>		
Male	Less than 10 pg/mL	Less than 10 ng/L
Female	Less than 5 pg/mL	Less than 5 ng/L
<i>Maximum Response</i>		
5 min after calcium and pentagastrin stimulation		
Male	8–343 pg/mL	8–343 ng/L
Female	Less than 39 pg/mL	Less than 39 ng/L
5 min after calcium stimulation		
Male	Less than 190 pg/mL	Less than 190 ng/L
Female	Less than 130 pg/mL	Less than 130 ng/L
5 min after pentagastrin stimulation		
Male	Less than 110 pg/mL	Less than 110 ng/L
Female	Less than 30 pg/mL	Less than 30 ng/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Alcoholic cirrhosis (*related to release of calcium from body stores associated with acute instances of malnutrition*)
- Cancer of the breast, lung, and pancreas (*related to metastasis of calcitonin-producing cells to other organs*)
- Carcinoid syndrome (*related to calcitonin-producing tumor cells*)
- C-cell hyperplasia (*related to increased production due to hyperplasia*)
- Chronic renal failure (*related to increased excretion of calcium and retention of phosphorus resulting in release of calcium from body stores; C cells respond to an increase in serum calcium levels*)
- Ectopic secretion (*especially neuroendocrine origins*)
- Hypercalcemia (any cause) (*related to increased production*

by C cells in response to increased calcium levels)

- Medullary thyroid cancer (*related to overproduction by cancerous cells*)
- MEN type II (*related to calcitonin-producing tumor cells*)
- Pancreatitis (*related to alcoholism or hypercalcemia*)
- Pernicious anemia (*related to hypergastrinemia*)
- Pheochromocytoma (*related to calcitonin-producing tumor cells*)
- Pregnancy (late) (*related to increased maternal loss of circulating calcium to developing fetus; release of calcium from maternal stores stimulates increased release of calcitonin*)
- Pseudohypoparathyroidism (*related to release of calcium from body stores initiates feedback response from C cells*)
- Thyroiditis (*related to calcitonin-producing tumor cells*)
- Zollinger-Ellison syndrome (*related to hypergastrinemia*)

Calcium, Blood

SYNONYM/ACRONYM: Total calcium, Ca.

COMMON USE: To investigate various conditions related to abnormally increased or decreased calcium levels.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.25)
Cord	8.2–11.2 mg/dL	2.1–2.8 mmol/L
0–10 days	7.6–10.4 mg/dL	1.9–2.6 mmol/L
11 days–2 yr	9–11 mg/dL	2.2–2.8 mmol/L
3–12 yr	8.8–10.8 mg/dL	2.2–2.7 mmol/L
13–18 yr	8.4–10.2 mg/dL	2.1–2.6 mmol/L
Adult	8.2–10.2 mg/dL	2.1–2.6 mmol/L
Adult older than 90 yr	8.2–9.6 mg/dL	2.1–2.4 mmol/L

DESCRIPTION: Calcium, the most abundant cation in the body, participates in almost all of the body's vital processes. Calcium concentration is largely regulated by the parathyroid glands and by the action of vitamin D. Of the body's calcium reserves, 98% to 99% is stored in the teeth and skeleton. Calcium values are higher in children because of growth and active bone formation. About 45% of the total amount of blood calcium circulates as free ions that participate in numerous regulatory functions to include bone development and maintenance, blood coagulation, transmission of nerve impulses, activation of enzymes, stimulating the glandular secretion of hormones, and control of skeletal and cardiac muscle contractility. The remaining calcium is bound to circulating proteins (40% bound mostly to albumin) and anions (15% bound to anions such as bicarbonate, citrate, phosphate, and lactate) and plays no physiological role. Calcium values can be adjusted up or down by 0.8 mg/dL for every 1 g/dL that albumin is greater than or less than 4 g/dL. Calcium and phosphorus levels are inversely proportional.

Fluid and electrolyte imbalances are often seen in patients with serious illness or injury; in

these clinical situations, the normal homeostatic balance of the body is altered. During surgery or in the case of a critical illness, bicarbonate, phosphate, and lactate concentrations can change dramatically. Therapeutic treatments may also cause or contribute to electrolyte imbalance. This is why total calcium values can sometimes be misleading. Abnormal calcium levels are used to indicate general malfunctions in various body systems. Ionized calcium is used in more specific conditions (see monograph titled "Calcium, Ionized").

Calcium values should be interpreted in conjunction with results of other tests. Normal calcium with an abnormal phosphorus value indicates impaired calcium absorption (possibly because of altered parathyroid hormone level or activity). Normal calcium with an elevated urea nitrogen value indicates possible hyperparathyroidism (primary or secondary). Normal calcium with decreased albumin value is an indication of hypercalcemia (high calcium levels). The most common cause of hypocalcemia (low calcium levels) is hypoalbuminemia. The most common causes of hypercalcemia are hyperparathyroidism and cancer (with or without bone metastases).

This procedure is contraindicated for: N/A

INDICATIONS

- Detect parathyroid gland loss after thyroid or other neck surgery, as indicated by decreased levels
- Evaluate cardiac arrhythmias and coagulation disorders to determine if altered serum calcium level is contributing to the problem
- Evaluate the effects of various disorders on calcium metabolism, especially diseases involving bone
- Monitor the effectiveness of therapy being administered to correct abnormal calcium levels, especially calcium deficiencies
- Monitor the effects of renal failure and various drugs on calcium levels

POTENTIAL DIAGNOSIS

Increased in

- Acidosis (*related to imbalance in electrolytes; longstanding acidosis can result in osteoporosis and release of calcium into circulation*)
- Acromegaly (*related to alteration in vitamin D metabolism, resulting in increased calcium*)
- Addison's disease (*related to adrenal gland dysfunction; decreased blood volume and dehydration occur in the absence of aldosterone*)
- Cancers (bone, Burkitt's lymphoma, Hodgkin's lymphoma, leukemia, myeloma, and metastases from other organs)
- Dehydration (*related to a decrease in the fluid portion of blood, causing an overall increase in the concentration of most plasma constituents*)
- Hyperparathyroidism (*related to increased parathyroid hormone [PTH] and vitamin D levels, which increase circulating calcium levels*)

- Idiopathic hypercalcemia of infancy
- Lung disease (tuberculosis, histoplasmosis, coccidioidomycosis, berylliosis) (*related to activity by macrophages in the epithelium that interfere with vitamin D regulation by converting it to its active form; vitamin D increases circulating calcium levels*)
- Malignant disease without bone involvement (*some cancers [e.g., squamous cell carcinoma of the lung and kidney cancer] produce PTH-related peptide that increases calcium levels*)
- Milk-alkali syndrome (Burnett's syndrome) (*related to excessive intake of calcium-containing milk or antacids, which can increase calcium levels*)
- Paget's disease (*related to calcium released from bone*)
- Pheochromocytoma (*hyperparathyroidism related to multiple endocrine neoplasia type 2A [MEN2A] syndrome associated with some pheochromocytomas; PTH increases calcium levels*)
- Polycythemia vera (*related to dehydration; decreased blood volume due to excessive production of red blood cells*)
- Renal transplant (*related to imbalances in electrolytes; a common post-transplant issue*)
- Sarcoidosis (*related to activity by macrophages in the granulomas that interfere with vitamin D regulation by converting it to its active form; vitamin D increases circulating calcium levels*)
- Thyrotoxicosis (*related to increased bone turnover and release of calcium into the blood*)
- Vitamin D toxicity (*vitamin D increases circulating calcium levels*)

Decreased in

- Acute pancreatitis (*complication of pancreatitis related to hypoal-*

buminemia and calcium binding by excessive fats)

- Alcoholism (*related to insufficient nutrition*)
- Alkalosis (*increased blood pH causes intracellular uptake of calcium to increase*)
- Chronic renal failure (*related to decreased synthesis of vitamin D*)
- Cystinosis (*hereditary disorder of the renal tubules that results in excessive calcium loss*)
- Hepatic cirrhosis (*related to impaired metabolism of vitamin D and calcium*)
- Hyperphosphatemia (*phosphorus and calcium have an inverse relationship*)
- Hypoalbuminemia (*related to insufficient levels of albumin, an important carrier protein*)
- Hypomagnesemia (*lack of magnesium inhibits PTH and thereby decreases calcium levels*)
- Hypoparathyroidism (congenital, idiopathic, surgical) (*related to lack of PTH*)
- Inadequate nutrition
- Leprosy (*related to increased bone retention*)
- Long-term anticonvulsant therapy (*these medications block calcium channels and interfere with calcium transport*)
- Malabsorption (celiac disease, tropical sprue, pancreatic insufficiency) (*related to insufficient absorption*)
- Massive blood transfusion (*related to the presence of citrate preservative in blood product that chelates or binds calcium and removes it from circulation*)
- Neonatal prematurity
- Osteomalacia (advanced) (*bone loss is so advanced there is little calcium remaining to be released into circulation*)
- Renal tubular disease (*related to decreased synthesis of vitamin D*)

- Vitamin D deficiency (rickets) (*related to insufficient amounts of vitamin D, resulting in decreased calcium metabolism*)

CRITICAL FINDINGS

- Less than 7 mg/dL (SI: Less than 1.8 mmol/L)
- Greater than 12 mg/dL (SI: Greater than 3 mmol/L) (some patients can tolerate higher concentrations)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Observe the patient for symptoms of critically decreased or elevated calcium levels. Hypocalcemia is evidenced by convulsions, arrhythmias, changes in electrocardiogram (ECG) in the form of prolonged ST segment and Q-T interval, facial spasms (positive Chvostek's sign), tetany, lethargy,

muscle cramps, numbness in extremities, tingling, and muscle twitching (positive Trousseau's sign). Possible interventions include seizure precautions, increased frequency of ECG monitoring, and administration of calcium or magnesium.

Severe hypercalcemia is manifested by excessive thirst, polyuria, constipation, changes in ECG (shortened QT interval due to shortening of the ST segment and prolonged PR interval), lethargy, confusion, muscle weakness, joint aches, apathy, anorexia, headache, nausea, vomiting, and ultimately may result in coma. Possible interventions include the administration of normal saline and diuretics to speed up dilution and excretion or administration of calcitonin or steroids to force the circulating calcium into the cells.

INTERFERING FACTORS

- Drugs that may increase calcium levels include anabolic steroids, some antacids, calcitriol, calcium salts, danazol, diuretics (long-term), ergocalciferol, isotretinoin, lithium, oral contraceptives, parathyroid extract, parathyroid hormone, prednisone, progesterone, tamoxifen, vitamin A, and vitamin D.
- Drugs that may decrease calcium

- levels include albuterol, alprostadil, aminoglycosides, anticonvulsants, calcitonin, diuretics (initially), gastrin, glucagon, glucocorticoids, glucose, insulin, laxatives (excessive use), magnesium salts, methicillin, phosphates, plicamycin, sodium sulfate (given IV), tetracycline (in pregnancy), trazodone, and viomycin.
- Calcium exhibits diurnal variation; serial samples should be collected at the same time of day for comparison.
- Venous hemostasis caused by prolonged use of a tourniquet during venipuncture can falsely elevate calcium levels.
- Patients on ethylenediaminetetraacetic acid (EDTA) therapy (chelation) may show falsely decreased calcium values.
- Hemolysis and icterus cause false-positive results because of interference from biological pigments.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest if it is present in the IV solution, falsely increasing the result.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to organ inflammation and surrounding tissues; excessive alcohol intake; infection; bone deformity</i>)	Emotional symptoms of distress; crying; agitation; facial grimace; moaning; verbalization of pain; rocking motions; irritability; disturbed sleep; diaphoresis; altered blood pressure and heart rate; nausea; vomiting; self-report of pain	Collaborate with the patient and physician to identify the best pain management modality to provide relief; refrain from activities that may aggravate pain; use the application of heat or cold to the best effect in managing the pain; monitor pain severity

Problem	Signs & Symptoms	Interventions
Health management <i>(Related to failure to regulate diet; lack of exercise; alcohol use; smoking)</i>	Inability or failure to recognize or process information toward improving health and preventing illness with associated mental and physical effects	Encourage regular participation in weight-bearing exercise; assess diet, smoking, and alcohol use; teach the importance of adequate calcium intake with diet and supplements; refer to smoking cessation and alcohol treatment programs; collaborate with physician for bone density evaluation
Nutrition <i>(Related to inability to digest foods, metabolize foods, ingest foods; refusal to eat; increased metabolic needs associated with disease process; lack of understanding; inability to obtain healthy foods)</i>	Unintended weight loss; current weight 20% below ideal weight; pale, dry skin; dry mucous membranes; documented inadequate caloric intake; subcutaneous tissue loss; hair pulls out easily; paresthesia	Obtain accurate daily weight at the same time each day with the same scale; obtain an accurate nutritional history; assess attitude toward eating; promote a dietary consult to evaluate current eating habits and best method of nutritional supplementation; develop short-term and long-term eating strategies; monitor nutritional laboratory values such as albumin, transferrin, red blood cells (RBC), white blood cells (WBC), and serum electrolytes; discourage caffeinated and carbonated beverages; assess swallowing ability; encourage cultural home foods; provide a pleasant environment for eating; alter food seasoning to enhance flavor; provide parenteral or enteral nutrition as prescribed
Injury risk <i>(Related to phosphorus retention; bone resorption;)</i>	Tingling sensation in the fingertips and around the mouth; muscle cramps; tetany; seizures; bone pain; weakness; unsteady	Assess for signs and symptoms of hypocalcemia; monitor calcium and phosphorus levels; provide medication replacement therapy as

(table continues on page 346)

Problem	Signs & Symptoms	Interventions
<i>inadequate calcium resorption; acute or chronic renal failure; lack of dietary vitamin D; decreased sun exposure; eating disorders)</i>	gait; laryngospasm; cardiac dysrhythmias; hyperactive tendon reflexes	prescribed; assess for bone pain; assess for alterations in mobility; increase the calcium in the diet; encourage the minimum recommended sun exposure

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist as a general indicator in diagnosing health concerns.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, gastrointestinal, genitourinary, hematopoietic, hepatobiliary, and musculoskeletal systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and assess the patient for signs and symptoms of calcium imbalance. Teach the patient the signs and symptoms associated with a calcium imbalance. Assess associated studies

such as ECG, phosphorus, and albumin so the correct therapeutic measures can be taken.

Hypoalbuminemia may initiate symptoms of hypocalcemia in the presence of near-normal calcium levels.

- ▶ **Nutritional Considerations:** Patients with abnormal calcium values should be informed that daily intake of calcium is important even though body stores in the bones can be called on to supplement circulating levels. Dietary calcium can be obtained from animal or plant sources. Milk and milk products, sardines, clams, oysters, salmon, rhubarb, spinach, beet greens, broccoli, kale, tofu, legumes, and fortified orange juice are high in calcium. Milk and milk products also contain vitamin D and lactose, which assist calcium absorption. Cooked vegetables yield more absorbable calcium than raw vegetables. Patients should be informed of the substances that can inhibit calcium absorption by irreversibly binding to some of the calcium, making it unavailable for absorption, such as oxalates, which naturally occur in some vegetables (e.g., beet greens, collards, leeks, okra, parsley, quinoa, spinach, Swiss chard) and are found in tea; phytic acid, found in some cereals (e.g., wheat bran, wheat germ); phosphoric acid, found in dark cola; and insoluble dietary fiber (in excessive amounts). Excessive protein intake can also negatively affect calcium absorption, especially if it is combined with foods high in phosphorus and in the presence of a reduced dietary calcium intake.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

- ▶ Educate the patient regarding access to nutritional counseling services.
- ▶ Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
- ▶ Teach the patient and family the importance of adequate dietary calcium intake to maintain health.
- ▶ Teach the patient that good oral hygiene prior to eating can improve the food's flavor.

Expected Patient Outcomes:

Knowledge

- ▶ Validates that eating in a pleasant environment with companionship can enhance the appetite
- ▶ States that parenteral or enteral nutrition may be used if oral intake is insufficient to support caloric needs

Skills

- ▶ Performs an accurate daily self-weight and records the results correctly
- ▶ Accurately self-administers prescribed dietary supplements

Attitude

- ▶ Complies with the request to take prescribed calcium replacement therapy
- ▶ Arranges consultation with the speech therapist to evaluate swallowing ability

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, albumin, aldosterone, ALP, biopsy bone marrow, BMD, bone scan, calcitonin, calcium ionized, urine calcium, calculus kidney stone analysis, catecholamines, chloride, collagen cross-linked telopeptides, CBC, CT pelvis, CT spine, cortisol, CK and isoenzymes, DHEA, fecal fat, glucose, HVA, magnesium, metanephrines, osteocalcin, PTH, phosphorus, potassium, protein total, radiography bone, renin, sodium, thyroid scan, thyroxine, US abdomen, US thyroid and parathyroid, UA, and vitamin D.
- ▶ Refer to the Cardiovascular, Gastrointestinal, Genitourinary, Hematopoietic, Hepatobiliary, and Musculoskeletal systems tables at the end of the book for related tests by body system.

Calcium, Ionized

SYNONYM/ACRONYM: Free calcium, unbound calcium, Ca^{++} , Ca^{2+} .

COMMON USE: To investigate various conditions related to altered levels of ionized calcium such as hypocalcemia and hypercalcemia.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Specimen should be transported tightly capped and remain unopened until testing. Exposure of serum to room air changes the pH of the specimen due to the release of carbon dioxide and can cause erroneous results.

NORMAL FINDINGS: (Method: Ion-selective electrode)

Age	Conventional Units	SI Units (Conventional Units \times 0.25)
Whole blood		
0–11 mo	4.2–5.84 mg/dL	1.05–1.46 mmol/L
1 yr-Adult	4.6–5.08 mg/dL	1.15–1.27 mmol/L
Plasma		
Adult	4.12–4.92 mg/dL	1.03–1.23 mmol/L
Serum		
1–18 yr	4.8–5.52 mg/dL	1.2–1.38 mmol/L
Adult	4.64–5.28 mg/dL	1.16–1.32 mmol/L

DESCRIPTION: Calcium, the most abundant cation in the body, participates in almost all of the body's vital processes (see other calcium studies). Circulating calcium is found in the free or ionized form; bound to organic anions such as lactate, phosphate, or citrate; and bound to proteins such as albumin. Ionized calcium is the physiologically active form of circulating calcium. About half of the total amount of calcium circulates as free ions that participate in blood coagulation, neuromuscular conduction, intracellular regulation, glandular secretion, and control of skeletal and cardiac muscle contractility. Calcium levels are regulated largely by the parathyroid glands and by vitamin D;

calcium levels are inversely proportional to PTH levels. Vitamin D enhances GI absorption of calcium. Compared to total calcium level, ionized calcium is a better measurement of calcium metabolism. Ionized calcium levels are not influenced by protein concentrations, as seen in patients with hypoalbuminemia, chronic renal failure, nephrotic syndrome, malabsorption, and multiple myeloma. Levels are also not affected in patients with metabolic acid-base balance disturbances. Elevations in ionized calcium may be seen when the total calcium is normal. Measurement of ionized calcium is useful to monitor patients undergoing cardiothoracic

surgery or organ transplantation. It is also useful in the evaluation of patients in cardiac arrest.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect ectopic parathyroid hormone (PTH)-producing neoplasms
- Evaluate the effect of protein on calcium levels
- Identify individuals with hypocalcemia
- Identify individuals with toxic levels of vitamin D
- Investigate suspected hyperparathyroidism
- Monitor patients with renal failure or organ transplantation in whom secondary hyperparathyroidism may be a complication
- Monitor patients with sepsis or magnesium deficiency

POTENTIAL DIAGNOSIS

Increased in

- Hyperparathyroidism (*related to increased PTH*)
- PTH-producing neoplasms (*PTH increases calcium levels*)
- Vitamin D toxicity (*related to increased absorption of calcium*)

Decreased in

- Burns, severe (*related to increased amino acid release*)
- Hypoparathyroidism (primary) (*related to decreased PTH*)
- Magnesium deficiency (*inhibits release of PTH*)
- Multiple organ failure
- Pancreatitis (*associated with saponification or binding of calcium to fats in tissue surrounding the pancreas*)
- The postdialysis period (*result of low-calcium dialysate administration*)

- The postsurgical period (i.e., major surgeries) (*related to decreased PTH*)
- The post-transfusion period (*result of the use of citrated blood product preservative [calcium chelator]*)
- Premature infants with hypoproteinemia and acidosis (*related to alterations in transport protein levels*)
- Pseudohypoparathyroidism (*related to decreased PTH*)
- Sepsis (*related to decreased PTH*)
- Trauma (*related to decreased PTH*)
- Vitamin D deficiency (*related to decreased absorption of calcium*)

CRITICAL FINDINGS

- Less than 3.2 mg/dL (SI: Less than 0.8 mmol/L)
- Greater than 6.2 mg/dL (SI: Greater than 1.6 mmol/L)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record

with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Observe the patient for symptoms of critically decreased or elevated calcium levels. Hypocalcemia is evidenced by convulsions, arrhythmias, changes in electrocardiogram (ECG) in the form of prolonged ST segment and Q-T interval, facial spasms (positive Chvostek's sign), tetany, lethargy, muscle cramps, numbness in extremities, tingling, and muscle twitching (positive Trousseau's sign). Possible interventions include seizure precautions, increased frequency of ECG monitoring, and administration of calcium or magnesium.

Severe hypercalcemia is manifested by excessive thirst, polyuria, constipation, changes in ECG (shortened QT interval due to shortening of the ST segment and prolonged PR interval), lethargy, confusion, muscle weakness, joint aches, apathy, anorexia, headache, nausea, vomiting, and ultimately may result in coma. Possible interventions include the administration of normal saline and diuretics to speed up excretion or administration of calcitonin or steroids to force the circulating calcium into the cells.

INTERFERING FACTORS

- Drugs that may increase calcium levels include antacids (some), calcitriol, and lithium.
- Drugs that may decrease calcium levels include calcitonin, citrates, foscarnet, and pamidronate (initially).
- Calcium exhibits diurnal variation; serial samples should be collected at the same time of day for comparison.
- Venous hemostasis caused by prolonged use of a tourniquet during

venipuncture can falsely elevate calcium levels.

- Patients on ethylenediaminetetraacetic acid (EDTA) therapy (chelation) may show falsely decreased calcium values.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest if it is present in the IV solution, falsely increasing the result.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating the level of blood calcium.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, gastrointestinal, genitourinary, hematopoietic, hepatobiliary, and musculoskeletal systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that could interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is

important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture and, without using a tourniquet, collect the specimen.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ The specimen should be stored under anaerobic conditions after collection to prevent the diffusion of gas from the specimen. Falsely decreased values result from unstoppered specimens. Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Patients with abnormal calcium values should be informed that daily intake of calcium is important even though body stores in the bones can be called on to supplement circulating levels. Dietary calcium can be obtained from animal or plant sources. Milk and milk products, sardines, clams, oysters, salmon,

rhubarb, spinach, beet greens, broccoli, kale, tofu, legumes, and fortified orange juice are high in calcium. Milk and milk products also contain vitamin D and lactose, which assist calcium absorption. Cooked vegetables yield more absorbable calcium than raw vegetables. Patients should be informed of the substances that can inhibit calcium absorption by irreversibly binding to some of the calcium, making it unavailable for absorption, such as oxalates, which naturally occur in some vegetables (e.g., beet greens, collards, leeks, okra, parsley, quinoa, spinach, Swiss chard) and are found in tea; phytic acid, found in some cereals (e.g., wheat bran, wheat germ); phosphoric acid, found in dark cola; and insoluble dietary fiber (in excessive amounts). Excessive protein intake can also negatively affect calcium absorption, especially if it is combined with foods high in phosphorus and in the presence of a reduced dietary calcium intake.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include albumin, ALP, calcitonin, calcium, calculus kidney stone panel, gastrin and gastrin stimulation, magnesium, PTH, parathyroid scan, phosphorus, potassium, protein total, sodium, thyroglobulin, US thyroid and parathyroid, UA, and vitamin D.
- ▶ Refer to the Cardiovascular, Gastrointestinal, Genitourinary, Hematopoietic, Hepatobiliary, and Musculoskeletal systems tables at the end of the book for related tests by body system.

Calcium, Urine

SYNONYM/ACRONYM: N/A.

COMMON USE: To indicate sufficiency of dietary calcium intake and rate of absorption. Urine calcium levels are also used to assess bone resorption, renal stones, and renal loss of calcium.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units*	SI Units (Conventional Units × 0.025)*
Infant and child	Up to 6 mg/kg per 24 hr	Up to 0.15 mmol/kg per 24 hr
Adult on average diet	100–300 mg/24 hr	2.5–7.5 mmol/24 hr

*Values depend on diet.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Acromegaly (*related to imbalance in vitamin D metabolism*)
- Diabetes (*related to increased loss from damaged kidneys*)
- Fanconi's syndrome (*evidenced by hereditary or acquired disorder of the renal tubules that results in excessive calcium loss*)
- Glucocorticoid excess (*related to action of glucocorticoids, which is to decrease the gastrointestinal absorption of calcium and increase urinary excretion*)
- Hepatolenticular degeneration (Wilson's disease) (*related to excessive electrolyte loss due to renal damage*)
- Hyperparathyroidism (*related to increased levels of PTH which result in increased calcium levels*)
- Hyperthyroidism (*related to increased bone turnover; excess circulating calcium is excreted by the kidneys*)
- Idiopathic hypercalciuria
- Immobilization (*related to disruption in calcium homeostasis and bone loss*)
- Kidney stones (*evidenced by excessive urinary calcium; contributes to the formation of kidney stones*)
- Leukemia and lymphoma (some instances)
- Myeloma (*calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys*)
- Neoplasm of the breast or bladder (*some cancers secrete PTH or PTH-related peptide that increases calcium levels*)
- Osteitis deformans (*calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys*)

- Osteolytic bone metastases (carcinoma, sarcoma) (*calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys*)
- Osteoporosis (*calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys*)
- Paget's disease (*calcium is released from damaged bone; excess circulating calcium is excreted by the kidneys*)
- Renal tubular acidosis (*metabolic acidosis resulting in loss of calcium by the kidneys*)
- Sarcoidosis (*macrophages in the granulomas interfere with vitamin D regulation by converting it to its active form; vitamin D increases circulating calcium levels, and excess is excreted by the kidneys*)
- Schistosomiasis
- Thyrotoxicosis (*increased bone turnover; excess circulating calcium is excreted by the kidneys*)
- Vitamin D intoxication (*increases calcium metabolism; excess is excreted by the kidneys*)

Decreased in

- Hypocalcemia (other than renal disease)
- Hypocalciuric hypercalcemia (familial, nonfamilial)
- Hypoparathyroidism (*PTH instigates release of calcium; if PTH levels are low, calcium levels will be decreased*)
- Hypothyroidism
- Malabsorption (celiac disease, tropical sprue) (*related to insufficient levels of calcium*)
- Malignant bone neoplasm
- Nephrosis and acute nephritis (*related to decreased synthesis of vitamin D*)
- Osteoblastic metastases
- Osteomalacia (*related to vitamin D deficiency*)
- Pre-eclampsia
- Pseudohypoparathyroidism
- Renal osteodystrophy
- Rickets (*related to deficiency in vitamin D*)
- Vitamin D deficiency (*deficiency in vitamin D results in decreased calcium levels*)

CRITICAL FINDINGS: N/A

Calculus, Kidney Stone Panel

SYNONYM/ACRONYM: Kidney stone analysis, nephrolithiasis analysis.

COMMON USE: To identify the presence of kidney stones.

SPECIMEN: Kidney stones.

NORMAL FINDINGS: (Method: Infrared spectrometry) None detected.

DESCRIPTION: Renal calculi (kidney stones) are formed by the crystallization of calcium oxalate (most common), magnesium ammonium phosphate, calcium phosphate, uric acid, and cystine. Formation of stones may be hereditary, related to diet or poor hydration, urinary tract infections caused by urease-producing bacteria, conditions resulting in reduced urine flow, or excessive amounts of the previously mentioned insoluble substances due to other predisposing conditions. The presence of stones is confirmed by diagnostic visualization or passing of the stones in the urine. The chemical nature of the stones is confirmed qualitatively. Analysis also includes a description of color, size, and weight.

This procedure is contraindicated for: N/A

INDICATIONS

- Identify substances present in renal calculi

POTENTIAL DIAGNOSIS

Positive findings in

Presence of calcium calculi (75–85%)

- Decreased levels of citric acid, which creates an imbalance of mineral salts (*related to conditions such as enteric hyperoxaluria, enterocystoplasty, or small bowel resection*)
- Distal renal tubular acidosis (*related to accumulation of calcium in the kidneys*)
- Etiology unknown
- Increased levels of calcium with or without alkaline pH, which creates an imbalance of mineral salts (*related to conditions such as*

Cushing's disease, Dent's disease, enterocystoplasty, ileostomy, immobilization, medullary sponge kidney, metabolic syndrome, milk alkali syndrome, primary biliary cirrhosis, primary hyperparathyroidism, sarcoidosis, Sjögren's syndrome, use of calcium carbonate-containing antacids, use of corticosteroids, or vitamin D intoxication)

- Increased levels of oxalic acid, which creates an imbalance of mineral salts (*related to conditions such as bariatric surgery, enteric hyperoxaluria, enterocystoplasty, hereditary hyperoxaluria, hypomagnesemia, jejunal-ileal bypass, metabolic syndrome, pancreatitis, or small bowel resection*)
- Increased levels of uric acid, which creates an imbalance of mineral salts (uric acid crystals sometimes provide the base upon which calcium oxalate crystals grow)

Presence of magnesium ammonium phosphate (struvite or triple phosphate) calculi (10–15%)

- Urinary tract infection (*related to chronic indwelling catheter, neurogenic bladder dysfunction, obstruction, or urinary diversion*)
- Gram-positive bacteria associated with development of struvite calculi include *Bacillus* species, *Corynebacterium* species, *Peptococcus asaccharolyticus*, *Staphylococcus aureus*, and *Staphylococcus epidermidis*
- Gram-negative bacteria associated with development of struvite calculi include *Bacteroides corrodens*, *Flavobacterium* species, *Klebsiella* species, *Pasteurella* species, *Proteus* species, *Providencia stuartii*, *Pseudomonas aeruginosa*, *Serratia marcescens*, *Ureaplasma urealyticum*, and *Yersinia enterocolitica*

- Yeast associated with development of struvite calculi include *Candida humicola*, *Cryptococcus* species, *Rhodotorula* species, *Sporobolomyces* species, and *Trichosporon cutaneum*

Presence of uric acid calculi (5–8%)

- Increased levels of uric acid or increased urinary excretion of uric acid
- Anemias (pernicious, lead poisoning) (*related to cellular destruction and turnover*)
- Chemotherapy and radiation therapy (*related to high cell turnover*)
- Gout (*usually related to excess dietary intake*)
- Glycogen storage disease type I (von Gierke's disease) (*related to a genetic deficiency of the enzyme G-6-P-D, ultimately resulting in hyperuricemia, increased production of uric acid via the pentose phosphate pathway, and increased purine catabolism*)
- Hemoglobinopathies (sickle cell anemia, thalassemias) (*related to cellular destruction and turnover*)
- Ileostomy (*related to imbalances in mineral salts*)
- Lesch-Nyhan syndrome (*related to a disorder of uric acid metabolism*)

- Metabolic syndrome (*elevated uric acid levels are associated with metabolic syndrome; there is evidence that uric acidemia is a risk factor for cardiovascular and renal disease*)
- Polycythemia (*related to increased cellular destruction*)
- Psoriasis (*related to increased skin cell turnover*)
- Tumors (*related to high cell turnover*)

Presence of cystine calculi (approximately 1%)

- Fanconi's syndrome (hereditary hypercystinuria) (*related to increased excretion of cystine*)

Negative findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that may increase the formation of urine calculi include probenecid and vitamin D.
- Adhesive tape should not be used to attach stones to any transportation or collection container, because the adhesive interferes with infrared spectrometry.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to obstruction of urinary flow by stone, presence of stone, movement of stone</i>)	Report of pain, restlessness, grimace, moan, sleeplessness, diaphoretic, nausea, vomiting; elevated blood pressure	Administer prescribed medication for pain; assesses effectiveness of pain medication and trend outcome; assess characteristics of pain (location, duration); consider nonpharmacological pain interventions that have worked for the patient in the past

(table continues on page 356)

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to stasis; interrupted urinary flow; gravel; urinary tract instrumentation</i>)	Temperature; elevated white blood cell (WBC) count; cloudy urine; sediment in urine; blood in urine	Monitor urinary output; assess urine color, odor, presence of blood; monitor and trend temperature and WBC count; obtain urine for culture and sensitivity as required; encourage fluid intake in excess of 3,000 mL/day; administer prescribed antibiotics
Knowledge (<i>Related to unfamiliarity of factors related to the development of kidney stones; unfamiliarity with disease management; methods of disease prevention</i>)	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management; renal stone reoccurrence	Assess understanding of renal stone formation; assess for a family history of renal stones; assess patient's understanding of the relationship between fluid intake and stone formation; strain urine; limit protein intake to decrease risk of stone formation; add cranberry juice to dietary intake; administer prescribed medications to decrease stone formation (cholestyramine, thiazide, allopurinol)
Elevated temperature (<i>Related to infection secondary to stone formation</i>)	Elevated temperature; flushed; warm skin; diaphoresis	Assess the patient's temperature frequently; encourage the use of light bedding and lightweight clothing to prevent overheating; increase fluid intake to offset insensible fluid loss; encourage bathing with tepid water for comfort and promotion of cooling; administer prescribed medication for elevated temperature

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the presence of kidney stones.
- ▶ Obtain a history of the patient's complaints, especially hematuria, recurrent urinary tract infection, and

abdominal pain. Also, obtain a list of known allergens.

- ▶ Obtain a history of the patient's genitourinary system and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

Review the procedure with the patient. Address concerns about pain and explain that there may be some discomfort during the procedure.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

Instruct the patient to cooperate fully and to follow directions.

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

The patient presenting with symptoms indicating the presence of kidney stones may be provided with a device to strain the urine. The patient should be informed to transfer any particulate matter remaining in the strainer into the specimen collection container provided. Stones removed by the health-care provider (HCP) should be placed in the appropriate collection container.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

Inform the patient with kidney stones that the likelihood of recurrence is high. Educate the patient regarding risk factors that contribute to the likelihood of kidney stone formation, including family history, osteoporosis, urinary tract infections, gout, magnesium deficiency, Crohn's disease with prior resection, age, gender (males are two to three times more likely than females

to develop stones), race (whites are three to four times more likely than African Americans to develop stones), and climate.

Nutritional Considerations: Nutritional therapy is indicated for individuals identified as being at high risk for developing kidney stones. Educate the patient that diets rich in protein, salt, and oxalates increase the risk of stone formation. Adequate fluid intake should be encouraged.

Recognize anxiety related to test results.

Follow-up testing of urine may be requested, but usually not for 1 mo after the stones have passed or been removed. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

Discuss the implications of abnormal test results on the patient's lifestyle.

Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

Teach patient to report worsening symptoms of infection such as fever, chills, and pain.

Expected Patient Outcomes:

Knowledge

States the process and importance of straining all urine

States the importance of increasing fluid intake and adding cranberry juice to their diet

Skills

Accurately self-administers prescribed medication

Demonstrates proficiency in straining urine to check for stones

Attitude

- Complies with the recommendation to increase fluid intake to more than 3,000 mL/day
- Discusses the importance in reporting changes in the characteristics of the urine in relation to infection risk

RELATED MONOGRAPHS:

- Related tests include CT abdomen, calcium, creatinine clearance, culture

bacterial urine, cystoscopy, IVP, KUB, magnesium, oxalate, phosphorus, potassium, renogram, retrograde ureteropyelography, US abdomen, US kidney, uric acid, and UA.

- Refer to the Genitourinary System table at the end of the book for related tests by body system.

Cancer Antigens: CA 15-3, CA 19-9, CA 125, and Carcinoembryonic

SYNONYM/ACRONYM: Carcinoembryonic antigen (CEA), cancer antigen 125 (CA 125), cancer antigen 15-3 (CA 15-3), cancer antigen 19-9 (CA 19-9), cancer antigen 27.29 (CA 27.29).

COMMON USE: To identify the presence of various cancers, such as breast and ovarian, as well as to evaluate the effectiveness of cancer treatment.

SPECIMEN: Serum (1 mL) collected in a red-top tube. Care must be taken to use the same assay method if serial measurements are to be taken.

NORMAL FINDINGS: (Method: Electrochemiluminometric immunoassay)

Smoking Status	Conventional Units	SI Units (Conventional Units × 1)
CEA		
Smoker	Less than 5.0 ng/mL	Less than 5.0 mcg/L
Nonsmoker	Less than 2.5 ng/mL	Less than 2.5 mcg/L

Conventional Units	SI Units (Conventional Units × 1)
CA 125	
Less than 35 units/mL	Less than 35 kU/L
CA 15-3	
Less than 25 units/mL	Less than 25 kU/L
CA 19-9	
Less than 35 units/mL	Less than 35 kU/L
CA 27.29	
Less than 38.6 units/mL	Less than 38.6 kU/L

DESCRIPTION: Carcinoembryonic antigen (CEA) is a family of 36 different glycoproteins whose function is believed to be involved in cell adhesion. These structurally related proteins are part of the immunoglobulin superfamily. CEA is normally produced during fetal development and rapid multiplication of epithelial cells, especially those of the digestive system. A small amount of circulating CEA is detectable in the blood of normal adults; normal half-life is 7 days. The liver is the main site for metabolism of CEA. Because of the variability in CEA molecules the test is not diagnostic for any specific disease and is not useful as a screening test for cancer. However, it is very useful for monitoring response to therapy in breast, liver, colon, and gastrointestinal cancer. Serial monitoring is also a useful indicator of recurrence or metastasis in colon or liver carcinoma. CEA levels are higher in the blood of smokers than in non-smokers so most laboratories will have a normal range for each group.

CA 125 or Muc16 is a glycoprotein member of the mucin family and is present in normal endometrial tissue. It appears in the blood when natural endometrial protective barriers are destroyed, as occurs in cancer or endometriosis. CA 125 is most useful in monitoring the progression or recurrence of known ovarian cancer. It is not useful as a screening test because elevations can occur with numerous other conditions such as endometriosis, other diseases of the ovary, menstruation, pregnancy, and uterine fibroids. Persistently rising levels indicate a poor prognosis. Levels may also rise in pancreatic, liver,

colon, breast, and lung cancers. Absence of detectable levels of CA 125 does not rule out the presence of tumor.

CA 15-3 monitors patients for recurrence or metastasis of breast carcinoma.

CA 19-9 is a carbohydrate antigen used for post-therapeutic monitoring of patients with gastrointestinal, pancreatic, liver, and colorectal cancer.

CA 27.29 is a glycoprotein product of the muc-1 gene. It is most useful as a serial monitor for response to therapy or recurrence of breast carcinoma.

This procedure is contraindicated for: N/A

INDICATIONS

CEA

- Determine stage of colorectal cancer and test for recurrence or metastasis
- Monitor response to treatment of breast and gastrointestinal cancers

CA 125

- Assist in the diagnosis of carcinoma of the cervix and endometrium
- Assist in the diagnosis of ovarian cancer
- Monitor response to treatment of ovarian cancer

CA 15-3 and CA 27.29

- Monitor recurrent carcinoma of the breast

CA 19-9

- Monitor effectiveness of therapy
- Monitor gastrointestinal, head and neck, and gynecological carcinomas
- Predict recurrence of cholangiocarcinoma

- Predict recurrence of stomach, pancreatic, colorectal, gallbladder, liver, and urothelial carcinomas

POTENTIAL DIAGNOSIS

Increased in

CEA

- Benign tumors, including benign breast disease
- Chronic tobacco smoking
- Cirrhosis
- Colorectal, pulmonary, gastric, pancreatic, breast, head and neck, esophageal, ovarian, and prostate cancer
- Inflammatory bowel disease
- Pancreatitis
- Radiation therapy (transient)

CA 125

- Breast, colon, endometrial, liver, lung, ovarian, and pancreatic cancer
- Endometriosis
- First-trimester pregnancy
- Menses
- Ovarian abscess
- Pelvic inflammatory disease
- Peritonitis

CA 15-3 and CA 27.29

- Recurrence of breast carcinoma

CA 19-9

- Gastrointestinal, head and neck, and gynecologic carcinomas
- Recurrence of stomach, pancreatic, colorectal, gallbladder, liver, and urothelial carcinomas
- Recurrence of cholangiocarcinoma

Decreased in

- Effective therapy or removal of the tumor

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in monitoring the progress of various types of disease and evaluate response to therapy.
- ▶ Obtain a history of the patient's complaints, including a list of known allergies, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal, immune, and reproductive systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Determine if the patient smokes, because smokers may have false elevations of CEA.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 minutes. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the

patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Association (www.cancer.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of breast self-examination, mammography, MRI breast, or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society (ACS) recommends breast examinations be performed every 3 yr for women between the ages of 20 and 39 yr and annually for women over 40 yr of age; annual mammograms should be performed on women 40 yr

and older as long as they are in good health. The ACS also recommends annual MRI testing for women at high risk of developing breast cancer. Genetic testing for inherited mutations (BRCA1 and BRCA2) associated with increased risk of developing breast cancer may be ordered for women at risk. The test is performed on a blood specimen. The most current guidelines for breast cancer screening of the general population as well as of individuals with increased risk are available from the American Cancer Society (www.cancer.org), the American College of Obstetricians and Gynecologists (ACOG) (www.acog.org), and the American College of Radiology (www.acr.org). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Decisions regarding the need for and frequency of occult blood testing, colonoscopy, or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society recommends regular screening for colon cancer, beginning at age 50 yr for individuals without identified risk factors. Their recommendations for frequency of screening: annual for occult blood testing (fecal occult blood testing [FOBT]) and fecal immunochemical testing [FIT]; every 5 yr for flexible sigmoidoscopy, double contrast barium enema, and CT colonography; and every 10 yr for colonoscopy. There are both advantages and disadvantages to the screening tests that are available today. Methods to use DNA testing of stool are being investigated and awaiting FDA approval. The DNA test is designed to identify abnormal changes in DNA from the cells in the lining of the colon that are normally shed and excreted in stool. The DNA tests under development would use multiple markers to identify colon cancers with various, abnormal DNA changes and would be able to detect precancerous polyps. The most current guidelines for colon cancer screening of the general population as

well as of individuals with increased risk are available from the American Cancer Society (www.cancer.org), U.S. Preventive Services Task Force (www.uspreventiveservicestaskforce.org), and the American College of Gastroenterology (www.gi.org).

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patients symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include barium enema, biopsy breast, biopsy cervical, biopsy intestinal, biopsy liver, capsule endoscopy, colonoscopy, colposcopy, fecal analysis, HCG, liver and spleen scan, MRI breast, MRI liver, mammogram, stereotactic breast biopsy, proctosigmoidoscopy, radiofrequency ablation liver, US abdomen, US breast, and US liver.
- ▶ Refer to the Gastrointestinal, Immune, and Reproductive systems tables at the end of the book for related tests by body system.

Capsule Endoscopy

SYNONYM/ACRONYM: Pill GI endoscopy.

COMMON USE: To assist in visualization of the GI tract to identify disease such as tumor and inflammation.

AREA OF APPLICATION: Esophagus, stomach, upper duodenum, and small bowel.

CONTRAST: None.

DESCRIPTION: This outpatient procedure involves ingesting a small (size of a large vitamin pill) capsule that is wireless and contains a small video camera that will pass naturally through the digestive system while taking pictures of the intestine. The capsule is 11 mm by 30 mm and contains a camera, light source, radio transmitter, and battery. The patient swallows the capsule, and the camera takes and transmits two images per second. The images are transmitted to a recording device, which saves all images for review later by a health-care provider (HCP). This device is

approximately the size of a personal compact disk player. The recording device is worn on a belt around the patient's waist, and the video images are transmitted to aerials taped to the body and stored on the device. After 8 hr, the device is removed and returned to the HCP for processing. Thousands of images are downloaded onto a computer for viewing by an HCP specialist. The capsule is disposable and will be excreted naturally in the patient's bowel movements. In the rare case that it is not excreted naturally, it will need to be removed endoscopically or surgically.

This procedure is contraindicated for

-  Patients who have had surgery involving the stomach or duodenum, **which can make locating the duodenal papilla difficult.**
-  Patients with a bleeding disorder.
-  Patients with unstable cardiopulmonary status, blood coagulation defects, or cholangitis, unless the patient received prophylactic antibiotic therapy before the test (otherwise, the examination must be rescheduled).
-  Patients with unstable cardiopulmonary status, blood coagulation defects, known aortic arch aneurysm, large esophageal Zenker's diverticulum, recent gastrointestinal (GI) surgery, esophageal varices, or known esophageal perforation.

INDICATIONS

- Assist in differentiating between benign and neoplastic tumors
- Detect gastric or duodenal ulcers
- Detect gastrointestinal tract (GI) inflammatory disease
- Determine the presence and location of GI bleeding and vascular abnormalities
- Evaluate the extent of esophageal injury after ingestion of chemicals
- Evaluate stomach or duodenum after surgical procedures
- Evaluate suspected gastric obstruction
- Identify Crohn's disease, infectious enteritis, and celiac sprue
- Identify source of chronic diarrhea
- Investigate the cause of abdominal pain, celiac syndrome, and other malabsorption syndromes

POTENTIAL DIAGNOSIS

Normal findings in

- Esophageal mucosa is normally yellow-pink. At about 9 in. from the

incisor teeth, a pulsation indicates the location of the aortic arch. The gastric mucosa is orange-red and contains rugae. The proximal duodenum is reddish and contains a few longitudinal folds, whereas the distal duodenum has circular folds lined with villi. No abnormal structures or functions are observed in the esophagus, stomach, or duodenum.

Abnormal findings in

- Achalasia
- Acute and chronic gastric and duodenal ulcers
- Crohn's disease, infectious enteritis, and celiac sprue
- Diverticular disease
- Duodenal cancer, diverticula, and ulcers
- Duodenitis
- Esophageal or pyloric stenosis
- Esophageal varices
- Esophagitis or strictures
- Gastric cancer, tumors, and ulcers
- Gastritis
- Hiatal hernia
- Mallory-Weiss syndrome
- Perforation of the esophagus, stomach, or small bowel
- Polyps
- Small bowel tumors
- Strictures
- Tumors (benign or malignant)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.

Other considerations

- The patient should not be near any electromagnetic source, such as

magnetic resonance imaging (MRI) or amateur (ham) radio equipment.

- Undergoing an MRI during the procedure may result in serious damage to the patient's intestinal tract or abdomen. The patient should contact his or her HCP for evaluation prior to any other procedure.
- Delayed capsule transit times may be a result of narcotic use, somatostatin use, gastroparesis, or psychiatric illness.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the esophagus, stomach, and upper intestines for disease.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that this procedure is performed before an upper GI series or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note time and date of last dose.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that no pain will be experienced during the procedure. Inform the patient that the procedure is begun

in a GI laboratory or office, usually by an HCP or support staff, and that it takes approximately 30 to 60 min to begin the procedure.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to stop taking medications that have a coating effect, such as sucralfate and Pepto-Bismol, 3 days before the procedure.
- ▶ Instruct the patient to abstain from the use of tobacco products for 24 hr prior to the procedure.
- ▶ Instruct the patient to start a liquid diet on the day before the procedure. From 10 p.m. the evening before the procedure, the patient should not eat or drink except for necessary medication with a sip of water. Instruct the patient to take a standard bowel prep the night before the procedure. Protocols may vary among facilities.
- ▶ Instruct the patient not to take any medication for 2 hr prior to the procedure.
- ▶ Inform the patient that there is a chance of intestinal obstruction associated with the procedure.
- ▶ Instruct the patient to wear loose, two-piece clothing on the day of the procedure. This assists with the placement of the sensors on the patient's abdomen.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure.**

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary and medication restrictions and pretesting preparations for at least 8 hr prior to the procedure.
- ▶ Obtain accurate height, weight, and abdominal girth measurements prior to beginning the examination.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Ask the patient to ingest the capsule with a full glass of water. The water

may have simethicone in it to reduce gastric and bile bubbles.

- ▶ After ingesting the capsule, the patient should not eat or drink for at least 2 hr. After 4 hr, the patient may have a light snack.
- ▶ After ingesting the capsule and until it is excreted, the patient should not be near any source of powerful electromagnetic fields, such as MRI or amateur (ham) radio equipment.
- ▶ The procedure lasts approximately 8 hr.
- ▶ Instruct the patient not to disconnect the equipment or remove the belt at any time during the test.
- ▶ If the data recorder stops functioning, instruct the patient to record the time and the nature of any event such as eating or drinking.
- ▶ Instruct the patient to keep a timed diary for the day detailing the food and liquids ingested and symptoms during the recording period.
- ▶ Instruct the patient to avoid any strenuous physical activity, bending, or stooping during the test.

POST-TEST:

- ▶ Instruct the patient to resume normal activity, medication, and diet after the test is ended or as tolerated after the examination, as directed by the HCP.
- ▶ Instruct the patient to remove the recorder and return it to the HCP.
- ▶ Patients are asked to verify the elimination of the capsule but not to retrieve the capsule.
- ▶ Inform the patient that the capsule is a single-use device that does not harbor any environmental hazards.
- ▶ Emphasize that any abdominal pain, fever, nausea, vomiting, or difficulty breathing must be immediately reported to the HCP.
- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing,

treatment, or referral to another HCP. Decisions regarding the need for and frequency of occult blood testing, colonoscopy, or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society recommends regular screening for colon cancer, beginning at age 50 yr for individuals without identified risk factors. Their recommendations for frequency of screening: annual for occult blood testing (fecal occult blood testing [FOBT] and fecal immunochemical testing [FIT]); every 5 yr for flexible sigmoidoscopy, double contrast barium enema, and computed tomography (CT) colonography; and every 10 yr for colonoscopy. There are both advantages and disadvantages to the screening tests that are available today. Methods to use DNA testing of stool are being investigated and await FDA approval. The DNA test is designed to identify abnormal changes in DNA from the cells in the lining of the colon that are normally shed and excreted in stool. The DNA tests under development use multiple markers to identify colon cancers that demonstrate different, abnormal DNA changes. Unlike some of the current screening methods, the DNA tests would be able to detect precancerous polyps. The most current guidelines for colon cancer screening of the general population as well as of individuals with increased risk are available from the American Cancer Society (www.cancer.org), U.S. Preventive Services Task Force (www.uspreventiveservicestaskforce.org), and the American College of Gastroenterology (www.gi.org). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include barium enema, barium swallow, biopsy intestinal, cancer antigens, colonoscopy, CT

abdomen, CT colonoscopy, esophageal manometry, esophagogastroduodenoscopy, fecal analysis, folate, gastric acid emptying scan, gastric acid stimulation test, gastrin, *Helicobacter pylori*, KUB studies, MRI abdomen,

PET pelvis, proctosigmoidoscopy, upper GI and small bowel series, US abdomen, and vitamin B₁₂.

Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Carbon Dioxide

SYNONYM/ACRONYM: CO₂ combining power, CO₂, TCO₂.

COMMON USE: To assess the effect of total carbon dioxide levels on respiratory and metabolic acid-base balance.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube, plasma (1 mL) collected in a green-top (lithium or sodium heparin) tube; or whole blood (1 mL) collected in a green-top (lithium or sodium heparin) tube or heparinized syringe.

NORMAL FINDINGS: (Method: Colorimetry, enzyme assay, or Pco₂ electrode)

Carbon Dioxide

Conventional & SI Units

Plasma or serum (venous)

Infant–2 yr

2 yr–older adult

13–29 mEq/L or mmol/L

23–29 mEq/L or mmol/L

Whole blood (venous)

Infant–2 yr

2 yr–older adult

18–28 mEq/L or mmol/L

22–26 mEq/L or mmol/L

DESCRIPTION: Serum or plasma carbon dioxide (CO₂) measurement is usually done as part of an electrolyte panel. Total CO₂ (Tco₂) is an important component of the body's buffering capability, and measurements are used mainly in the evaluation of acid-base balance. It is important to understand the differences between Tco₂ (CO₂ content) and CO₂ gas (Pco₂). Total CO₂ reflects the majority of CO₂ in the body, mainly in the form of bicarbonate (HCO₃⁻); is present as a

base; and is regulated by the kidneys. CO₂ gas contributes little to the Tco₂ level, is acidic, and is regulated by the lungs (see monograph titled "Blood Gases").

CO₂ provides the basis for the principal buffering system of the extracellular fluid system, which is the bicarbonate–carbonic acid buffer system. CO₂ circulates in the body either bound to protein or physically dissolved. Constituents in the blood that contribute to Tco₂ levels are bicarbonate,

carbamino compounds, and carbonic acid (carbonic acid includes undissociated carbonic acid and dissolved CO_2). Bicarbonate is the second-largest group of anions in the extracellular fluid (chloride is the largest). TCO_2 levels closely reflect bicarbonate levels in the blood, because 90% to 95% of CO_2 circulates as HCO_3^- .

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate decreased venous CO_2 in the case of compensated metabolic acidosis
- Evaluate increased venous CO_2 in the case of compensated metabolic alkalosis
- Monitor decreased venous CO_2 as a result of compensated respiratory alkalosis
- Monitor increased venous CO_2 as a result of compensation for respiratory acidosis secondary to significant respiratory system infection or cancer; decreased respiratory rate

POTENTIAL DIAGNOSIS

Increased in

- Interpretation requires clinical information and evaluation of other electrolytes
- Acute intermittent porphyria (related to severe vomiting associated with acute attacks)
- Airway obstruction (related to impaired elimination from weak breathing responses)
- Asthmatic shock (related to impaired elimination from abnormal breathing responses)
- Brain tumor (related to abnormal blood circulation)
- Bronchitis (chronic) (related to impaired elimination from weak breathing responses)

- Cardiac disorders (related to lack of blood circulation)
- Depression of respiratory center (related to impaired elimination from weak breathing responses)
- Electrolyte disturbance (severe) (response to maintain acid-base balance)
- Emphysema (related to impaired elimination from weak breathing responses)
- Hypothyroidism (related to impaired elimination from weak breathing responses)
- Hypoventilation (related to impaired elimination from weak breathing responses)
- Metabolic alkalosis (various causes; excessive vomiting)
- Myopathy (related to impaired ventilation)
- Pneumonia (related to impaired elimination from weak breathing responses)
- Poliomyelitis (related to impaired elimination from weak breathing responses)
- Respiratory acidosis (related to impaired elimination)
- Tuberculosis (pulmonary) (related to impaired elimination from weak breathing responses)

Decreased in

- Interpretation requires clinical information and evaluation of other electrolytes
- Acute renal failure (response to buildup of ketoacids)
- Anxiety (related to hyperventilation; too much CO_2 is exhaled)
- Dehydration (response to metabolic acidosis that develops)
- Diabetic ketoacidosis (response to buildup of ketoacids)
- Diarrhea (severe) (acidosis related to loss of base ions like HCO_3^- ; most of CO_2 content is in this form)
- High fever (response to neutralize acidosis present during fever)

- Metabolic acidosis (*response to neutralize acidosis*)
- Respiratory alkalosis (*hyperventilation; too much CO₂ is exhaled*)
- Salicylate intoxication (*response to neutralize related metabolic acidosis*)
- Starvation (*CO₂ buffer system used to neutralize buildup of ketoacids*)

CRITICAL FINDINGS

- Less than 15 mEq/L or mmol/L (SI: Less than 15 mmol/L)
- Greater than 40 mEq/L or mmol/L (SI: Greater than 40 mmol/L)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Observe the patient for signs and symptoms of excessive or insufficient CO₂ levels, and report these findings

to the HCP. If the patient has been vomiting for several days and is breathing shallowly, or if the patient has had gastric suctioning and is breathing shallowly, this may indicate elevated CO₂ levels. Decreased CO₂ levels are evidenced by deep, vigorous breathing and flushed skin.

INTERFERING FACTORS

- Drugs that may cause an increase in TCO₂ levels include acetylsalicylic acid, aldosterone, bicarbonate, carbenicillin, carbenoxolone, corticosteroids, dexamethasone, ethacrynic acid, laxatives (chronic abuse), and x-ray contrast agents.
- Drugs that may cause a decrease in TCO₂ levels include acetazolamide, acetylsalicylic acid (initially), amiloride, ammonium chloride, fluorides, metformin, methicillin, nitrofurantoin, NSD 3004 (long-acting carbonic anhydrase inhibitor), paraldehyde, tetracycline, triamterene, and xylitol.
- Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results. The specimen should be stored under anaerobic conditions after collection to prevent the diffusion of CO₂ gas from the specimen. Falsely decreased values result from uncovered specimens. It is estimated that CO₂ diffuses from the sample at the rate of 6 mmol/hr.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in measuring the amount of carbon dioxide in the body.
- ▶ Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's cardiovascular, genitourinary, and respiratory systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Abnormal CO₂ values may be associated with diseases of the respiratory system. Malnutrition is commonly seen in patients with severe respiratory disease for reasons including fatigue, lack of appetite, and gastrointestinal distress. Research has estimated that the daily caloric intake required for respiration of patients with chronic obstructive pulmonary disease is 10 times higher than that of normal individuals. Adequate intake of vitamins A and C is also important to prevent pulmonary infection and to decrease the extent of lung tissue damage. The importance of following the prescribed diet should be stressed to the patient and/or caregiver.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include anion gap, arterial/alveolar oxygen ratio, biopsy lung, blood gases, chest x-ray, chloride, cold agglutinin titer, CBC white blood cell count and differential, culture bacterial blood, culture bacterial sputum, culture mycobacterium, culture viral, cytology sputum, eosinophil count, ESR, gallium scan, Gram stain, IgE, ketones, lung perfusion scan, osmolality, phosphorus, plethysmography, pleural fluid analysis, potassium, PFT, pulse oximetry, salicylate, and US abdomen.
- ▶ Refer to the Cardiovascular, Genitourinary, and Respiratory systems tables at the end of the book for related tests by body system.

Carboxyhemoglobin

SYNONYM/ACRONYM: Carbon monoxide, CO, COHb, COH.

COMMON USE: To identify the amount of carbon monoxide in the blood related to poisoning, toxicity from smoke inhalation, or exhaust from cars.

SPECIMEN: Whole blood (1 mL) collected in a green-top (heparin) or lavender-top (EDTA) tube, depending on laboratory requirement. Specimen should be transported tightly capped (anaerobic) and in an ice slurry if blood gases are to be performed simultaneously. Carboxyhemoglobin is stable at room temperature.

NORMAL FINDINGS: (Method: Spectrophotometry, co-oximetry)

	% Saturation of Hemoglobin
Newborns	10–12%
Nonsmokers	Up to 2%
Smokers	Up to 10%

DESCRIPTION: Exogenous carbon monoxide (CO) is a colorless, odorless, tasteless by-product of incomplete combustion derived from the exhaust of automobiles, coal and gas burning, and tobacco smoke. Endogenous CO is produced as a result of red blood cell catabolism. CO levels are elevated in newborns as a result of the combined effects of high hemoglobin turnover and the inefficiency of the infant's respiratory system. CO binds tightly to hemoglobin with an affinity 250 times greater than oxygen, competitively and dramatically reducing the oxygen-carrying capacity of hemoglobin. The increased percentage of bound CO reflects the extent to which normal transport of oxygen has been negatively affected. Overexposure causes hypoxia, which results in headache, nausea, vomiting, vertigo,

collapse, or convulsions. Toxic exposure causes anoxia, increased levels of lactic acid, and irreversible tissue damage, which can result in coma or death. Acute exposure may be evidenced by a cherry red color to the lips, skin, and nail beds; this observation may not be apparent in cases of chronic exposure. A direct correlation has been implicated between carboxyhemoglobin levels and symptoms of atherosclerotic disease, angina, and myocardial infarction.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of suspected CO poisoning
- Evaluate the effect of smoking on the patient

- Evaluate exposure to fires and smoke inhalation

POTENTIAL DIAGNOSIS

Increased in

- CO poisoning

- Hemolytic disease (*CO released during red blood cell catabolism*)
- Tobacco smoking

Decreased in: N/A

CRITICAL FINDINGS

Percent of Total Hemoglobin	Symptoms
10%–20%	Asymptomatic
10%–30%	Disturbance of judgment, headache, dizziness
30%–40%	Dizziness, muscle weakness, vision problems, confusion, increased heart rate, increased breathing rate
50%–60%	Loss of consciousness, coma
Greater than 60%	Death

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Women and children may suffer more severe symptoms of carbon monoxide poisoning at lower levels of carbon monoxide than men because women and children usually have lower red blood cell counts.

A possible intervention in moderate CO poisoning is the administration of supplemental oxygen given at atmospheric pressure. In severe CO poisoning, hyperbaric oxygen treatments may be used.

INTERFERING FACTORS

- Specimen should be collected before administration of oxygen therapy.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating the extent of carbon monoxide poisoning or toxicity.
- ▶ Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's respiratory system and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Explain to the patient or family members that the cause of the headache, vomiting, dizziness, convulsions, or coma could be related to CO exposure. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ If carboxyhemoglobin measurement will be performed simultaneously with arterial blood gases, prepare an ice slurry in a cup or plastic bag and have it on hand for immediate transport of the specimen to the laboratory.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen,

date, and time of collection. Perform a venipuncture. The tightly capped sample should be placed in an ice slurry immediately after collection.

Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Educate the patient regarding avoiding gas heaters and indoor cooking fires without adequate ventilation and the need to have gas furnaces checked yearly for CO leakage. Inform the patient of smoking cessation programs, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include angiography pulmonary, arterial/alveolar oxygen ratio, blood gases, carbon dioxide, CBC, lung perfusion scan, lung

ventilation scan, plethysmography, and PFT.

Refer to the Respiratory System table at the end of the book for related tests by body system.

Catecholamines, Blood and Urine

SYNONYM/ACRONYM: Epinephrine, norepinephrine, dopamine.

COMMON USE: To assist in diagnosing catecholamine-secreting tumors, such as those found in the adrenal medulla, and in the investigation of hypertension. The urine test is used to assist in diagnosing pheochromocytoma and as a work-up of neuroblastoma.

SPECIMEN: Plasma (2 mL) collected in green-top (heparin) tube. Urine (25 mL) from a timed specimen collected in a clean, plastic, amber collection container with 6N hydrochloric acid as a preservative.

NORMAL FINDINGS: (Method: High-performance liquid chromatography)

Blood	Conventional Units	SI Units
<i>(Conventional Units × 5.46)</i>		
Epinephrine		
Newborn–1 yr	0–34 pg/mL	0–186 pmol/L
1–18 yr	0–80 pg/mL	0–437 pmol/L
Adult		
Supine, 30 min	0–110 pg/mL	0–600 pmol/L
Standing, 30 min	0–140 pg/mL	0–764 pmol/L
<i>(Conventional Units × 5.91)</i>		
Norepinephrine		
Newborn–1 yr	0–659 pg/mL	0–3,895 pmol/L
1–18 yr	0–611 pg/mL	0–3,611 pmol/L
Adult		
Supine, 30 min	70–750 pg/mL	414–4,432 pmol/L
Standing, 30 min	200–1,700 pg/mL	1,182–10,047 pmol/L
<i>(Conventional Units × 6.53)</i>		
Dopamine		
Newborn–1 yr	0–42 pg/mL	0–274 pmol/L
1–18 yr	0–32 pg/mL	0–209 pmol/L
Adult		
Supine or standing	0–48 pg/mL	0–313 pmol/L

Urine	Conventional Units	SI Units
<i>(Conventional Units × 5.46)</i>		
Epinephrine		
Newborn–9 yr	0–11 mcg/24 hr	0–60 nmol/24 hr
10–19 yr	0–18 mcg/24 hr	0–98 nmol/24 hr
20 yr–older adult	0–20 mcg/24 hr	0–109 nmol/24 hr
<i>(Conventional Units × 5.91)</i>		
Norepinephrine		
Newborn–9 yr	0–59 mcg/24 hr	0–349 nmol/24 hr
10–19 yr	0–90 mcg/24 hr	0–532 nmol/24 hr
20 yr–older adult	0–135 mcg/24 hr	0–798 nmol/24 hr
<i>(Conventional Units × 6.53)</i>		
Dopamine		
Newborn–9 yr	0–414 mcg/24 hr	0–2,703 nmol/24 hr
10–19 yr	0–575 mcg/24 hr	0–3,755 nmol/24 hr
20 yr–older adult	0–510 mcg/24 hr	0–3,330 nmol/24 hr

DESCRIPTION: Catecholamines are produced by the chromaffin tissue of the adrenal medulla. They also are found in sympathetic nerve endings and in the brain. The major catecholamines are epinephrine, norepinephrine, and dopamine. They prepare the body for the fight-or-flight stress response, help regulate metabolism, and are excreted from the body by the kidneys. Levels are affected by diurnal variations, fluctuating in response to stress, postural changes, diet, smoking, drugs, and temperature changes. As a result, blood measurement is not as reliable as a 24-hr timed urine test. For test results to be valid, all of the previously mentioned environmental variables must be controlled when the test is performed. Results of blood specimens are most reliable when the specimen is collected during a hypertensive

episode. Catecholamines are measured when there is high suspicion of pheochromocytoma but urine results are normal or borderline. Use of a clonidine suppression test with measurement of plasma catecholamines may be requested. Failure to suppress production of catecholamines after administration of clonidine supports the diagnosis of pheochromocytoma. Elevated homovanillic acid levels rule out pheochromocytoma because this tumor primarily secretes epinephrine. Elevated catecholamines without hypertension suggest neuroblastoma or ganglioneuroma. Findings should be compared with metanephrines and vanillylmandelic acid, which are the metabolites of epinephrine and norepinephrine. Findings should also be compared with homovanillic acid, which is the product of dopamine metabolism.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of neuroblastoma, ganglioneuroma, or dysautonomia
- Assist in the diagnosis of pheochromocytoma
- Evaluate acute hypertensive episode
- Evaluate hypertension of unknown origin
- Screen for pheochromocytoma among family members with an autosomal dominant inheritance pattern for Lindau-von Hippel disease or multiple endocrine neoplasia

POTENTIAL DIAGNOSIS

Increased in

- Diabetic acidosis (epinephrine and norepinephrine) (*related to metabolic stress; are released to initiate glycogenolysis, gluconeogenesis, and lipolysis*)
- Ganglioblastoma (epinephrine, slight increase; norepinephrine, large increase) (*related to production by the tumor*)
- Ganglioneuroma (all are increased; norepinephrine, largest increase) (*related to production by the tumor*)
- Hypothyroidism (epinephrine and norepinephrine) (*possibly related to interactions among the immune, endocrine, and nervous systems*)
- Long-term manic-depressive disorders (epinephrine and norepinephrine) (*some studies indicate a relationship between decreased catecholamine levels and manic depressive illnesses; the pathophysiology is not well understood*)

- Myocardial infarction (epinephrine and norepinephrine) (*related to physical stress*)
- Neuroblastoma (all are increased; norepinephrine and dopamine, largest increase) (*related to production by the tumor*)
- Pheochromocytoma (epinephrine, continuous or intermittent increase; norepinephrine, slight increase) (*related to production by the tumor*)
- Shock (epinephrine and norepinephrine) (*related to physical stress*)
- Strenuous exercise (epinephrine and norepinephrine) (*related to physical stress*)

Decreased in

- Autonomic nervous system dysfunction (norepinephrine)
- Orthostatic hypotension caused by central nervous system disease (norepinephrine) (*related to inability of sympathetic nervous system to activate postganglionic neuron*)
- Parkinson's disease (dopamine) (*some studies indicate a relationship between decreased catecholamine levels and Parkinson's disease; the pathophysiology is not well understood*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase plasma catecholamine levels include ajmaline, chlorpromazine, cyclopropane, diazoxide, ether, monoamine oxidase inhibitors, nitroglycerin, pentazocine, perphenazine, phenothiazine, promethazine, and theophylline.
- Drugs that may decrease plasma catecholamine levels include captopril, and reserpine.

- Drugs that may increase urine catecholamine levels include atenolol, isoproterenol, methyl dopa, niacin, nitroglycerin, prochlorperazine, rauwolfia, reserpine, syrosingopine, and theophylline.
- Drugs that may decrease urine catecholamine levels include bretylium tosylate, clonidine, decaborane, guanethidine, guanfacine, methyl dopa, ouabain, radiographic substances, and reserpine.
- Stress, hypoglycemia, smoking, and drugs can produce elevated catecholamines.
- Secretion of catecholamines exhibits diurnal variation, with the lowest levels occurring at night.
- Secretion of catecholamines varies during the menstrual cycle, with higher levels excreted during the luteal phase and lowest levels during ovulation.
- Diets high in amines (e.g., bananas, avocados, beer, aged cheese, chocolate, cocoa, coffee, fava beans, grains, tea, vanilla, walnuts, Chianti wine) can produce elevated catecholamine levels.
- Failure to collect all urine and store 24-hr specimen properly will yield a falsely low result.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this test can assist in the diagnosis of a type of tumor that produces excessive amounts of hormones related to physical and emotional stress.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the patient's last menstrual period.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient.

Blood

- ▶ Inform the patient that he or she may be asked to keep warm and to rest for 45 to 60 min before the test. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. Inform the patient that a saline lock may be inserted before the test because the stress of repeated venipunctures may increase catecholamine levels.

Urine

- ▶ Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain related to the procedure. Explain to the patient that there should be no discomfort during the procedure. Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine over a 24-hr period must be saved; if a preservative has been added to the container, instruct the patient not to

discard the preservative. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom as a reminder to save all urine. Instruct the patient to void all urine into the collection device, then pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.

Blood and Urine

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to follow a normal-sodium diet for 3 days before testing, abstain from smoking tobacco for 24 hr before testing, and avoid consumption of foods high in amines for 48 hr before testing.
- ▶ Instruct the patient to avoid self-prescribed medications for 2 wk before testing (especially appetite suppressants and cold and allergy medications, such as nose drops, cough suppressants, and bronchodilators).
- ▶ Instruct the patient to withhold prescribed medication (especially methyl dopa, epinephrine, levodopa, and methenamine mandelate) if directed by the health-care provider (HCP).
- ▶ Instruct the patient to withhold food and fluids for 10 to 12 hr before the test. Protocols may vary from facility to facility.
- ▶ Instruct the patient collecting a 24-hr urine specimen to avoid excessive stress and exercise during the test collection period.

- ▶ Prior to blood specimen collection, prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory. Prechill the collection tube in the ice slurry.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary, medication, and activity restrictions and with pretesting preparations; ensure that food and fluids have been restricted for at least 10 to 12 hr prior to the procedure, and that excessive exercise and stress have been avoided prior to the procedure. Instruct the patient to continue to avoid excessive exercise and stress during the 24-hr collection of urine.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture as appropriate.

Blood

- ▶ Perform a venipuncture between 6 and 8 a.m.; collect the specimen in a pre-chilled tube.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Ask the patient to stand for 10 min, and then perform a second venipuncture and obtain a sample as previously described.

- ▶ Each sample should be placed in an ice slurry immediately after collection. Information on the specimen labels should be protected from water in the ice slurry by first placing the specimens in a protective plastic bag. Promptly transport the specimens to the laboratory for processing and analysis.

Urine

- ▶ Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- ▶ Begin the test between 6 and 8 a.m. if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container.
- ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.

Blood and Urine

- ▶ Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography adrenal, calcitonin, CT renal, HVA, metanephrines, renin, and VMA.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

CD4/CD8 Enumeration

SYNONYM/ACRONYM: T-cell profile.

COMMON USE: To monitor HIV disease progression and the effectiveness of retroviral therapy.

SPECIMEN: Whole blood (1 mL) collected in a green-top (heparin) tube.

NORMAL FINDINGS: (Method: Flow cytometry)

	Mature T cells (CD3)		Helper T cells (CD4)		Suppressor T cells (CD8)	
	Absolute (cells/microL)	%	Absolute (cells/microL)	%	Absolute (cells/microL)	%
Age						
0–3 mo	2,500–5,500	53–84	1,600–4,000	35–64	560–1,700	12–28

Pediatric values adapted with permission by Elsevier from Shearer, W., et. al. (November, 2003). Lymphocyte subsets in healthy children from birth through 18 years of age: The pediatric AIDS clinical trials group P1009 study. *Journal of Allergy and Clinical Immunology*. 112(5): 973–980.

DESCRIPTION: Enumeration of lymphocytes, identification of cell lineage, and identification of cellular stage of development are used to diagnose and classify malignant myeloproliferative diseases and to plan treatment. T-cell enumeration is also useful in the evaluation and management of immunodeficiency and autoimmune disease. The CD4 count is a reflection of immune status. It is used to make decisions regarding initiation of antiretroviral therapy (ART) and is also an excellent predictor of

imminent opportunistic infection. A sufficient response for patients receiving ART is defined as an increase of 50 to 150 (cells/microL) per year with rapid response during the first 3 mo of treatment followed by an annual increase of 50 to 100 (cells/microL) until stabilization is achieved. HIV viral load is another important test used to establish a baseline for viral activity when a person is first diagnosed with HIV and then afterward to monitor response to ART. Viral load testing, also called plasma

HIV RNA, is performed on plasma from a whole blood sample. The viral load demonstrates how actively the virus is reproducing and helps determine whether treatment is necessary. Optimal viral load is considered to be less than 20 to 75 copies/mL or below the level of detection, but the actual level of detection varies somewhat by test method.

Methods commonly used to perform viral load testing include branched DNA (bDNA) or reverse transcriptase polymerase chain reaction (RT-PCR). Results are not interchangeable from method to method. Therefore, it is important to use the same viral load method for serial testing. Public health guidelines recommend CD4 counts and viral load testing upon initiation of care for HIV; 3 to 4 mo before commencement of ART; every 3 to 4 mo, but no later than 6 mo, thereafter; and if treatment failure is suspected or otherwise when clinically indicated.

Additionally, viral load testing should be requested 2 to 4 wk, but no later than 8 wk, after initiation of ART to verify success of therapy. In clinically stable patients, CD4 testing may be recommended every 6 to 12 mo rather than every 3 to 6 mo. Guidelines also state that treatment of asymptomatic patients should begin when CD4 count is less than 350 cells/microL; treatment is recommended when the patient is symptomatic regardless of test results or when the patient is asymptomatic and CD4 count is between 350 and 500 cells/microL. Failure to respond to therapy is defined as a viral load greater than 200 copies/mL. Increased viral load may be indicative of

viral mutations, drug resistance, or noncompliance to the therapeutic regimen. Testing for drug resistance is recommended if viral load is greater than 1,000 copies/mL.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of AIDS and plan treatment
- Evaluate malignant myeloproliferative diseases and plan treatment
- Evaluate thymus-dependent or cellular immunocompetence

POTENTIAL DIAGNOSIS

Increased in

- Malignant myeloproliferative diseases (e.g., acute and chronic lymphocytic leukemia, lymphoma)

Decreased in

- AIDS
- Aplastic anemia
- Hodgkin's disease

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase T-cell count include interferon- γ .
- Drugs that may decrease T-cell count include chlorpromazine and prednisone.
- Specimens should be stored at room temperature.
- Recent radioactive scans or radiation can decrease T-cell counts.
- Values may be abnormal in patients with severe recurrent illness or after recent surgery requiring general anesthesia.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Gas exchange (<i>Related to insufficient oxygen supply secondary to pulmonary infiltrates; sepsis; hyperventilation</i>)	Decreased activity tolerance; increased shortness of breath with activity; weakness; orthopnea; cyanosis; cough; increased heart rate; weight gain; edema in the lower extremities; weakness; increased respiratory rate; use of respiratory accessory muscles	Auscultate and trend breath sounds; use pulse oximetry to monitor oxygenation; administer oxygen as ordered; collaborate with physician to consider intubation and/or mechanical ventilation; place the head of the bed in high Fowler's position; administer diuretics, vasodilators as ordered; monitor arterial blood gas (ABG) results; monitor color and character of sputum; encourage periods of rest; administer prescribed medications for <i>Pneumocystis jiroveci</i> (Trimethoprim/ sulfamethoxazole [TMP-SMX], pentamidine), administer prescribed steroids
Infection (<i>Related to altered immune system; malnutrition; chemotherapy</i>)	Symptoms of infection (temperature, increased heart rate, increased blood pressure, shaking, chills, mottled skin, lethargy, fatigue, swelling, edema, pain, localized pressure, diaphoresis, night sweats, confusion, vomiting, nausea, headache); night sweats; persistent cough; adventitious breath sounds (crackles, course, diminished)	Decrease exposure to environment by placing the patient in a private room; monitor and trend vital signs; monitor and trend laboratory values that would indicate an infection (white blood cells [WBC], C-reactive protein [CRP]); promote good hygiene; assist with hygiene as needed; administer prescribed antibiotics, antipyretics; provide cooling measures; administer prescribed IV fluids; monitor vital signs and trend temperatures; encourage oral fluids; adhere to standard or

(table continues on page 382)

Problem	Signs & Symptoms	Interventions
Nutrition (<i>Related to fatigue; malabsorption; nausea [medication side effect]; effects of chemotherapy</i>)	Unintended weight loss; current weight 20% below ideal weight; skin tone loss and pale dry skin; dry mucous membranes; documented inadequate caloric intake; subcutaneous tissue loss; hair pulls out easily; paresthesia; muscle wasting	universal precautions; provide isolation as appropriate; obtain cultures as ordered; provide lightweight clothing and bedding; assess for night sweats; assess for cough and sputum color if productive, check for blood in sputum; use isolation as appropriate (TB); encourage use of incentive spirometer Obtain accurate daily weight at the same time each day with the same scale; obtain an accurate nutritional history; assess attitude toward eating; promote a dietary consult to evaluate current eating habits and best method of nutritional supplementation; develop short-term and long-term eating strategies; monitor nutritional laboratory values such as albumin, transferrin, red blood cells [RBC], WBC, and serum electrolytes; discourage caffeinated and carbonated beverages; assess swallowing ability; encourage cultural home foods; provide a pleasant environment for eating; alter food seasoning to enhance flavor; provide parenteral or enteral nutrition as prescribed, if used check gastric residual every 4 hr; encourage good oral hygiene; provide frequent small meals; administer prescribed antiemetics

Problem	Signs & Symptoms	Interventions
Tissue integrity (<i>Related to insufficient nutrition; vomiting and diarrhea secondary to medication side effects, chemotherapy; altered mobility</i>)	Area on the skin that is warm or tender to touch; skin that turns red, purple, or black; localized pain; swelling of affected area	Conduct baseline skin assessment of frequent re-assessment using a standardized scale (Braden); monitor and note the presence of herpes lesions; encourage the use of hypoallergenic soap and lanolin products, pat rather than rub skin dry; avoid bed wrinkles; ensure sheets are soft and gentle on skin; encourage adequate nutrition; administer prescribed vitamin supplements; encourage and assist range of motion; assess the characteristics of a wound (color, size, length, width, depth, drainage, and odor); monitor for fever; identify the cause of the tissue damage

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing disease and monitoring the effectiveness of disease therapy.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic and immune systems and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately

5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate

specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** As appropriate, stress the importance of good nutrition and suggest that the patient meet with a nutritional specialist. Stress the importance of following the care plan for medications and follow-up visits. Inform the patient that subsequent requests for follow-up blood work at regular intervals should be anticipated.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient as to the risk of infection related to immunosuppressed inflammatory response and fatigue related to decreased energy production. Educate the patient regarding access to counseling services.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen, including consultation with a pharmacist.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov).
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States the importance of reporting cough and shortness of breath to ensure early intervention of opportunistic hosts
- ▶ States steps that can be taken in the home environment to decrease infection risk

Skills

- ▶ Correctly describes the process for the collection of a sputum specimen
- ▶ Demonstrates proficient use of the incentive spirometer

Attitude

- ▶ Takes proactive measures to improve overall health by complying with recommended therapeutic plan
- ▶ Complies with the request to refrain from scratching, which causes tissue damage

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, bronchoscopy, CBC, CBC platelet count, CBC WBC count and differential, culture and smear mycobacteria, culture viral, cytology sputum, gallium scan, HIV-1/HIV-2 antibodies, laparoscopy abdominal, LAP, lymphangiogram, MRI musculoskeletal, mediastinoscopy, and β_2 -microglobulin.
- ▶ Refer to the Hematopoietic and Immune systems tables at the end of the book for related tests by body system.

Cerebrospinal Fluid Analysis

SYNONYM/ACRONYM: CSF analysis.

COMMON USE: To assist in the differential diagnosis of infection or hemorrhage of the brain. Also used in the evaluation of other conditions with significant neuromuscular effects, such as multiple sclerosis.

SPECIMEN: CSF (1 to 3 mL) collected in three or four separate plastic conical tubes. Tube 1 is used for chemistry and serology testing, tube 2 is used for microbiology, tube 3 is used for cell count, and tube 4 is used for miscellaneous testing.

NORMAL FINDINGS: (Method: Macroscopic evaluation of appearance; spectrophotometry for glucose, lactic acid, and protein; immunoassay for myelin basic protein; nephelometry for immunoglobulin G [IgG]; electrophoresis for oligoclonal banding; Gram stain, India ink preparation, and culture or PCR for microbiology; microscopic examination of fluid for cell count; flocculation for Venereal Disease Research Laboratory [VDRL])

Lumbar Puncture	Conventional Units	SI Units
Color and appearance	Crystal clear	
Protein		<i>(Conventional Units × 10)</i>
0–1 mo	Less than 150 mg/dL	Less than 1,500 mg/L
1–6 mo	30–100 mg/dL	300–1,000 mg/L
7 mo–adult	15–45 mg/dL	150–450 mg/L
Older adult	15–60 mg/dL	150–600 mg/L
		<i>(Conventional Units × 0.0555)</i>
Glucose		
Infant or child	60–80 mg/dL	3.3–4.4 mmol/L
Adult/older adult	40–70 mg/dL	2.2–3.9 mmol/L
		<i>(Conventional Units × 0.111)</i>
Lactic acid		
Neonate	10–60 mg/dL	1.1–6.7 mmol/L
3–10 days	10–40 mg/dL	1.1–4.4 mmol/L
Adult	Less than 25.2 mg/dL	Less than 2.8 mmol/L
		<i>(Conventional Units × 1)</i>
Myelin basic protein	Less than 4 ng/mL	Less than 4 mcg/L
Oligoclonal bands	Absent	
		<i>(Conventional Units × 10)</i>
IgG	Less than 3.4 mg/dL	Less than 34 mg/L
Gram stain	Negative	
India ink	Negative	

(table continues on page 386)

Lumbar Puncture	Conventional Units	SI Units
Culture	No growth	
RBC count	0	0
		(Conventional Units × 1)
WBC count		
Neonate–1 mo	0–30 /microL	0–30 × 10 ⁶ /L
1 mo–1 yr	0–10 /microL	0–10 × 10 ⁶ /L
1–5 yr	0–8 /microL	0–8 × 10 ⁶ /L
5 yr–adult	0–5 /microL	0–5 × 10 ⁶ /L
VDRL	Nonreactive	
Cytology	No abnormal cells seen	

CSF glucose should be 60%–70% of plasma glucose level.

RBC = red blood cell; VDRL = Venereal Disease Research Laboratory; WBC = white blood cell. Color should be assessed after sample is centrifuged.

WBC

Differential	Adult	Children
Lymphocytes	40%–80%	5%–13%
Monocytes	15%–45%	50%–90%
Neutrophils	0%–6%	0%–8%

DESCRIPTION: Cerebrospinal fluid (CSF) circulates in the subarachnoid space and has a twofold function: to protect the brain and spinal cord from injury and to transport products of cellular metabolism and neurosecretion. The total volume of CSF is 90 to 150 mL in adults and 60 mL in infants. CSF analysis helps determine the presence and cause of bleeding and assists in diagnosing cancer, infections, and degenerative and autoimmune diseases of the brain and spinal cord.

Specimens for analysis are most frequently obtained by lumbar puncture and sometimes by ventricular or cisternal puncture. Lumbar puncture can also have therapeutic uses, including injection of drugs and anesthesia. The subspecialty of microbiology has been revolutionized by molecular diagnostics. Molecular diagnostics involves the identification of specific sequences of DNA. The

application of molecular diagnostics techniques, such as PCR, has led to the development of automated instruments that can identify a single infectious agent or multiple pathogens from a cerebrospinal fluid sample in less than 2 hr. The instruments can detect the presence of bacteria, viruses, and yeast commonly associated with meningitis and encephalitis.

This procedure is contraindicated for

- Patients with infection present at the needle insertion site.
- Patients with degenerative joint disease or coagulation defects.
- Patients who are uncooperative during the procedure.
- Patients with increased intracranial pressure; extreme caution should be used **because overly rapid removal of CSF can result in herniation.**

INDICATIONS

- Assist in the diagnosis and differentiation of subarachnoid or intracranial hemorrhage
- Assist in the diagnosis and differentiation of viral or bacterial meningitis or encephalitis

- Assist in the diagnosis of diseases such as multiple sclerosis, autoimmune disorders, or degenerative brain disease
- Assist in the diagnosis of neurosyphilis and chronic central nervous system (CNS) infections
- Detect obstruction of CSF circulation due to hemorrhage, tumor, or edema
- Establish the presence of any condition decreasing the flow of oxygen to the brain
- Monitor for metastases of cancer into the CNS
- Monitor severe brain injuries

POTENTIAL DIAGNOSIS

Increased in

- Color and appearance (*xanthochromia is any pink, yellow, or orange color; bloody—hemorrhage; xanthochromic—old hemorrhage, red blood cell [RBC] breakdown, methemoglobin, bilirubin [greater than 6 mg/dL], increased protein [greater than 150 mg/dL], melanin [meningeal melanosis], carotene [systemic carotenemia]; bazy—meningitis; pink to dark yellow—aspiration of epidural fat; turbid—cells, microorganisms, protein, fat, or contrast medium*)
- Protein (*related to alterations in blood-brain barrier that allow permeability to proteins*): meningitis, encephalitis
- Lactic acid (*related to cerebral hypoxia and correlating anaerobic metabolism*): bacterial, tubercular, fungal meningitis
- Myelin basic protein (*related to accumulation as a result of nerve sheath demyelination*): trauma, stroke, tumor, multiple sclerosis, subacute sclerosing panencephalitis
- IgG and oligoclonal banding (*related to autoimmune or inflammatory response*): multiple sclerosis, CNS

syphilis, and subacute sclerosing panencephalitis

- Gram stain: *Meningitis due to Escherichia coli, Streptococcus agalactiae, Streptococcus pneumoniae, Haemophilus influenzae, Mycobacterium avium-intracellulare, Mycobacterium leprae, Mycobacterium tuberculosis, Neisseria meningitidis, Cryptococcus neoformans*
- India ink preparation: *Meningitis due to C. neoformans*
- Culture: *Encephalitis or meningitis due to herpes simplex virus, S. pneumoniae, H. influenzae, N. meningitidis, C. neoformans*
- RBC count: *Hemorrhage*
- White blood cell (WBC) count:

*General increase—*injection of contrast media or anticancer drugs in subarachnoid space; CSF infarct; metastatic tumor in contact with CSF; reaction to repeated lumbar puncture

Elevated WBC count with a predominance of neutrophils indicative of bacterial meningitis

Elevated WBC count with a predominance of lymphocytes indicative of viral, tubercular, parasitic, or fungal meningitis; multiple sclerosis

Elevated WBC count with a predominance of monocytes indicative of chronic bacterial meningitis, amebic meningitis, multiple sclerosis, toxoplasmosis

Increased plasma cells indicative of acute viral infections, multiple sclerosis, sarcoidosis, syphilitic meningoencephalitis, subacute sclerosing panencephalitis, tubercular meningitis, parasitic infections, Guillain-Barré syndrome

Presence of eosinophils indicative of parasitic and fungal infections, acute polyneuritis, idiopathic hypereosinophilic syndrome, reaction to drugs or a shunt in CSF

- VDRL: *Syphilis*

Positive findings in

- Cytology: *Malignant cells*

Decreased in

- Glucose: **Bacterial and tubercular meningitis**

CRITICAL FINDINGS 

- Positive Gram stain, India ink preparation, or culture
- Presence of malignant cells or blasts
- Elevated WBC count
- Adults: Glucose less than 37 mg/dL (SI: Less than 2.1 mmol/L); greater than 440 mg/dL (SI: Greater than 24.4 mmol/L)
- Children: Glucose less than 31 mg/dL (SI: Less than 1.7 mmol/L); greater than 440 mg/dL (SI: Greater than 24.4 mmol/L)

Note and immediately report to the health-care provider (HCP) any positive or critically increased results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS**Other considerations**

- Drugs that may decrease CSF protein levels include cefotaxime and dexamethasone.
- Interferon- β may increase myelin basic protein levels.
- Drugs that may increase CSF glucose levels include cefotaxime and dexamethasone.
- RBC count may be falsely elevated with a traumatic spinal tap.
- Delays in analysis may present a false positive appearance of xanthochromia due to RBC lysis that begins within 4 hr of a bloody tap.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating health by providing a sample of fluid from around the spinal cord to be tested for disease and infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- ▶ Obtain a history of the patient's immune and musculoskeletal systems and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that the position required may be awkward but that someone will assist during the procedure. Stress the importance of remaining still and breathing normally.

throughout the procedure. Inform the patient that specimen collection takes approximately 20 min. Address concerns about pain and explain that a stinging sensation may be felt when the local anesthetic is injected. Instruct the patient to report any pain or other sensations that may require repositioning the spinal needle. Explain that there may be some discomfort during the procedure. Inform the patient the procedure will be performed by an HCP.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Headache is a common minor complication experienced after lumbar puncture and is caused by leakage of the spinal fluid from around the puncture site. On a rare occasion the headache may require treatment with an epidural blood patch in which an anesthesiologist or pain management specialist injects a small amount of the patient's blood in the epidural space of the puncture site. The blood patch forms a clot and seals the puncture site to prevent further leakage of CSF and provides relief within 30 min. Other complications include lower back pain after the procedure, bleeding near the puncture site, or brainstem herniation, due to increased intracranial pressure.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure.

Number of days to withhold medication is dependent on the type of anticoagulant. Notify HCP if patient anticoagulant therapy has not been withheld.

- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Collect the specimen in four plastic conical tubes.
- ▶ Record baseline vital signs, and assess neurological status.
- ▶ To perform a lumbar puncture, position the patient in the knee-chest position at the side of the bed. Provide pillows to support the spine or for the patient to grasp. The sitting position is an alternative. In this position, the patient must bend the neck and chest to the knees.
- ▶ Prepare the site—usually between L3 and L4, or between L4 and L5—with povidone-iodine and drape the area.
- ▶ A local anesthetic is injected. Using sterile technique, the HCP inserts the spinal needle through the spinous processes of the vertebrae and into the subarachnoid space. Needle size has been shown to play a significant role in predictable incidence of post-puncture headache. However, the smaller the bevel, the more time is required to collect a sufficient volume of fluid; usually a 22 g needle is used. The stylet is removed. If the needle is properly placed, CSF drips from the needle.
- ▶ Attach the stopcock and manometer, and measure initial pressure. Normal pressure for an adult in the lateral recumbent position is 60–200 mm H₂O, and 10–100 mm H₂O for children less than 8 yr. These values depend on the body position and are different in a horizontal than in a sitting position.
- ▶ CSF pressure may be elevated if the patient is anxious, holding his or her breath, or tensing muscles. It may also

be elevated if the patient's knees are flexed too firmly against the abdomen. CSF pressure may be significantly elevated in patients with intracranial tumors or space occupying pockets of infection as seen in meningitis. If the initial pressure is elevated, the HCP may perform Queckenstedt's test. To perform this test, pressure is applied to the jugular vein for about 10 sec. CSF pressure usually rises rapidly in response to the occlusion and then returns to the pre-test level within 10 sec after the pressure is released. Sluggish response may indicate CSF obstruction.

- ▶ Obtain four (or five) vials of fluid, according to the HCP's request, in separate tubes (1 to 3 mL in each), and label them numerically (1 to 4 or 5) in the order they were filled.
- ▶ A final pressure reading is taken, and the needle is removed. Clean the puncture site with an antiseptic solution and apply direct pressure with dry gauze to stop bleeding or CSF leakage. Observe/assess puncture site for bleeding, CSF leakage, or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Monitor vital signs and neurological status and for headache every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Administer fluids if permitted, especially fluids containing caffeine, to replace lost CSF and help prevent or relieve headache, which is a side effect of lumbar puncture. Advise the patient that headache may begin within a few hours up to 2 days after the procedure and may be associated with dizziness, nausea, and vomiting. The length of time for the headache to resolve varies considerably.
- ▶ Observe/assess the puncture site for leakage, and frequently monitor body

signs, such as temperature and blood pressure. Position the patient flat, either on the back or abdomen following the HCP's instructions; some HCPs allow 30 degrees of elevation. Maintain this position for 8 hr. Changing position is acceptable as long as the body remains horizontal. Observe/assess the patient for neurological changes, such as altered level of consciousness, change in pupils, reports of tingling or numbness, and irritability.

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Provide information regarding vaccine-preventable diseases when indicated (encephalitis, influenza, meningococcal diseases). Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CBC, CT brain, culture for appropriate organisms (blood, fungal, mycobacteria, sputum, throat, viral, wound), EMG, evoked brain potentials, Gram stain, MRI brain, PET brain, and syphilis serology.
- ▶ Refer to the Immune and Musculoskeletal systems tables at the end of the book for related tests by body system.

Ceruloplasmin

SYNONYM/ACRONYM: Copper oxidase, Cp.

COMMON USE: To assist in the evaluation of copper intoxication and liver disease, especially Wilson's disease.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Nephelometry)

Age	Conventional Units	SI Units (Conventional Units × 10)
Newborn–3 mo	5–18 mg/dL	50–180 mg/L
6–12 mo	33–43 mg/dL	330–430 mg/L
1–3 yr	26–55 mg/dL	260–550 mg/L
4–5 yr	27–56 mg/dL	270–560 mg/L
6–7 yr	24–48 mg/dL	240–480 mg/L
8 yr–older adult	20–54 mg/dL	200–540 mg/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Ceruloplasmin is an acute-phase reactant protein and will be increased in many inflammatory conditions, including cancer

- Acute infections
- Biliary cirrhosis
- Cancer of the bone, lung, stomach
- Copper intoxication
- Hodgkin's disease
- Leukemia

- Pregnancy (last trimester) (*estrogen increases copper levels*)
- Rheumatoid arthritis
- Tissue necrosis

Decreased in

- Menkes' disease (*severe X-linked defect causing failed transport to the liver and tissues*)
- Nutritional deficiency of copper
- Wilson's disease (*genetic defect causing failed transport to the liver and tissues*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Chest X-Ray

SYNONYM/ACRONYM: Chest radiography, CXR, lung radiography.

COMMON USE: To assist in the evaluation of cardiac, respiratory, and skeletal structure within the lung cavity and diagnose multiple diseases such as pneumonia and congestive heart failure.

AREA OF APPLICATION: Heart, mediastinum, lungs.

CONTRAST: None.

DESCRIPTION: Chest radiography, commonly called chest x-ray, is one of the most frequently performed radiological diagnostic studies. This study yields information about the pulmonary, cardiac, and skeletal systems. The lungs, filled with air, are easily penetrated by x-rays and appear black on chest images. A routine chest x-ray includes a posteroanterior (PA) projection, in which x-rays pass from the posterior to the anterior, and a left lateral projection. Additional projections that may be requested are obliques, lateral decubitus, or lordotic views. Portable x-rays, done in acute or critical situations, can be done at the bedside and usually include only the anteroposterior (AP) projection with additional images taken in a lateral decubitus position if the presence of free pleural fluid or air is in question. Chest images should be taken on full inspiration and erect when possible to minimize heart magnification and demonstrate fluid levels. Expiration images may be added to detect a pneumothorax or locate foreign bodies. Rib detail images may be taken to delineate bone pathology, useful when chest radiographs suggest fractures or

metastatic lesions. Fluoroscopic studies of the chest can also be done to evaluate lung and diaphragm movement. In the beginning of the disease process of tuberculosis, asthma, and chronic obstructive pulmonary disease, the results of a chest x-ray may not correlate with the clinical status of the patient and may even be normal.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of diaphragmatic hernia, lung tumors, intravenous devices, and metastasis
- Evaluate known or suspected pulmonary disorders, chest trauma, cardiovascular disorders, and skeletal disorders
- Evaluate placement and position of an endotracheal tube, tracheostomy tube, nasogastric feeding tube, pacemaker wires, central venous

catheters, Swan-Ganz catheters, chest tubes, and intra-aortic balloon pump

- Evaluate positive purified protein derivative (PPD) or Mantoux tests
- Monitor resolution, progression, or maintenance of disease
- Monitor effectiveness of the treatment regimen

POTENTIAL DIAGNOSIS

Normal findings in

- Normal lung fields, cardiac size, mediastinal structures, thoracic spine, ribs, and diaphragm

Abnormal findings in

- Atelectasis
- Bronchitis
- Curvature of the spinal column (scoliosis)
- Enlarged heart
- Enlarged lymph nodes
- Flattened diaphragm
- Foreign bodies lodged in the pulmonary system *as seen by a radiopaque object*
- Fractures of the sternum, ribs, and spine
- Lung pathology, including tumors
- Malposition of tubes or wires
- Mediastinal tumor and pathology
- Pericardial effusion
- Pericarditis
- Pleural effusion
- Pneumonia
- Pneumothora
- Pulmonary bases, fibrosis, infiltrates
- Tuberculosis
- Vascular abnormalities

CRITICAL FINDINGS

- Foreign body
- Malposition of tube, line, or postoperative device (pacemaker)
- Pneumonia
- Pneumoperitoneum

- Pneumothorax
- Spine fracture

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair the results of the examination

- Metallic objects within the examination field.
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure.
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
 - ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the heart and lungs for disease.
 - ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
 - ▶ Obtain a history of the patient's cardiovascular and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
 - ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
 - ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
 - ▶ Review the procedure with the patient. Address concerns about pain and explain that no pain will be experienced during the test. Inform the patient that the procedure is performed in the radiology department or at the bedside by a registered radiological technologist, and takes approximately 5 to 15 min.
- Pediatric Considerations** Preparing children for a chest x-ray depends on the age of the child. Encourage parents to be truthful about what the child may experience during the procedure and to use words that they know their child will understand. Toddlers and preschool-age children have a very short attention span, so the best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with the child during the procedure. Provide older children with information about the test, and allow them to participate in as many decisions as possible (e.g., choice of clothes to wear to the appointment) in order to reduce anxiety and encourage cooperation. If the child will be asked to maintain a certain position for the test, encourage the child to practice the required position, provide a CD that demonstrates the procedure, and teach strategies to remain calm, such as deep breathing, humming, or counting to himself or herself.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
 - ▶ Instruct the patient to remove all metallic objects from the area to be examined.
 - ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined.
- ▶ Patients are given a gown, robe, and foot coverings to wear.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the standing position facing the cassette or image detector, with hands on hips, neck extended, and shoulders rolled forward.
- ▶ Position the chest with the left side against the image holder for a lateral view.
- ▶ For portable examinations, elevate the head of the bed to the high Fowler's position.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- ▶ Recognize anxiety related to test results and be supportive of impaired activity related to respiratory capacity and perceived loss of physical activity. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate and determine the need for a change in therapy or progression of the disease process. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy lung, blood gases, bronchoscopy, CT thoracic, CBC, culture mycobacteria, culture sputum, culture viral, electrocardiogram, Gram stain, lung perfusion scan, MRI chest, pulmonary function study, pulse oximetry, and TB tests.
- ▶ Refer to the Cardiovascular and Respiratory systems tables at the end of the book for related tests by body system.

Chlamydia Group Antibody, IgG and IgM

SYNONYM/ACRONYM: N/A.

COMMON USE: To diagnose some of the more common chlamydia infections such as community-acquired pneumonia transmitted by *C. pneumoniae* and chlamydia disease that is sexually transmitted by *Chlamydia trachomatis*.

SPECIMEN: Serum (1 mL) collected in a red-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Enzyme immunofluorescent assay)

IgG	IgM
Less than 1:64	Less than 1:20

DESCRIPTION: Chlamydia, one of the most common sexually transmitted diseases, is caused by *Chlamydia trachomatis*. These gram-negative bacteria are called *obligate cell parasites* because they require living cells for growth. There are three serotypes of *C. trachomatis*. One group causes lymphogranuloma venereum, with symptoms of the first phase of the disease appearing 2 to 6 wk after infection; another causes a genital tract infection different from lymphogranuloma venereum, in which symptoms in men appear 7 to 28 days after intercourse (women are generally asymptomatic); and the third causes the ocular disease trachoma (incubation period, 7 to 10 days). *C. psittaci* is the cause of psittacosis in birds and humans. It is increasing in prevalence as a pathogen responsible for other significant diseases of the respiratory system. The incubation period for *C. psittaci* infections in humans is 7 to 15 days and is followed by chills, fever, and a persistent nonproductive cough. *C. psittaci* is a common cause of community-acquired pneumonia. It is also less commonly associated with meningoencephalitis, arthritis, myocarditis, and Guillain-Barré syndrome.

Chlamydia is difficult to culture and grow, so antibody testing has become the technology of choice. A limitation of antibody screening is that positive results

may not distinguish past from current infection. The antigen used in many screening kits is not species specific and can confirm only the presence of *Chlamydia* species. Newer technology using nucleic acid amplification and DNA probes can identify the species. Assays that can specifically identify *C. trachomatis* require special collection and transport kits. They also have specific collection instructions, and the specimens are collected on swabs. The laboratory performing this testing should be consulted before specimen collection. Culture or liquid based PAP test may also be requested for identification of chlamydia.

This procedure is contraindicated for: N/A

INDICATIONS

- Establish *Chlamydia* as the cause of atypical pneumonia
- Establish the presence of chlamydial infection

POTENTIAL DIAGNOSIS

Positive findings in

- Chlamydial infection
- Community-acquired pneumonia
- Infantile pneumonia (*related to transmission at birth from an infected mother*)
- Infertility (*related to scarring of ovaries or fallopian tubes from untreated chlamydial infection*)
- Lymphogranuloma venereum
- Ophthalmia neonatorum (*related to transmission at birth from an infected mother*)
- Pelvic inflammatory disease
- Urethritis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Hemolysis or lipemia may interfere with analysis.
- Positive results may demonstrate evidence of past infection and not necessarily indicate current infection.

NURSING IMPLICATIONS AND PROCEDURE**Potential Nursing Problems:**

Problem	Signs & Symptoms	Interventions
Infection <i>(Related to exposure to bacterial organisms)</i>	Temperature; increased heart rate; increased blood pressure; shaking; chills; mottled skin; lethargy; fatigue; swelling; elevated white blood cell (WBC) count; sputum culture positive for infecting organism; tachypnea; dyspnea; productive cough; tachycardia	Promote good hygiene; assist with hygiene as needed; administer prescribed antibiotics, antipyretics; provide cooling measures; administer prescribed intravenous fluids; monitor vital signs and trend temperatures; encourage oral fluids; adhere to standard or universal precautions; provide isolation as appropriate; obtain cultures as ordered; provide lightweight clothing and bedding; assess and monitor breath sounds; obtain ordered sputum specimen for culture; monitor and trend WBC results; monitor chest x-ray results
Airway <i>(Related to congestion; sputum production)</i>	Ineffective cough; purulent sputum; dyspnea; tachypnea; documented infiltrates; decreased or diminished breath sounds	Assess respiratory characteristics (rate, rhythm, depth, accessory muscle use); assess effectiveness of cough and amount of productivity; monitor sputum characteristics (color, viscosity); assess hydration status, encourage increased fluid intake; auscultate lungs for adventitious breath sounds (crackles); use pulse oximetry; administer prescribed oxygen; suction as needed; humidify oxygen as appropriate;

(table continues on page 398)

Problem	Signs & Symptoms	Interventions
Gas exchange (<i>Related to congestion [fluid in alveoli or mucous in airways]; mucous secretions; ventilation and perfusion mismatch; lung consolidation</i>)	Decreased activity tolerance; increased shortness of breath with activity; weakness; orthopnea; cyanosis (pale, dusky); cough; increased heart rate; increased respiratory rate; use of respiratory accessory muscles; tachypnea; tachycardia; hypotension; restlessness; irritability; confusion; lethargy; disorientation; hypercapnia	encourage use of incentive spirometer; facilitate chest physiotherapy and nebulized treatments with mucolytic and bronchodilator medications; facilitate ordered bronchoscopy or thoracentesis Auscultate and trend breath sounds; use pulse oximetry to monitor oxygenation; administer oxygen as ordered; collaborate with physician to consider intubation and/or mechanical ventilation; place the head of the bed in high Fowler's position; administer diuretics, vasodilators as ordered; assess for hypoxia (nailbeds, mucous membranes); monitor and trend blood pressure and heart rate; monitor for altered level of consciousness
Infection (<i>Related to sexual exposure to C. trachomatis</i>)	Purulent penile or vaginal drainage; dysuria; lower abdominal pain in women (pelvic inflammatory disease); testicular pain and swelling (epididymitis); pain, bleeding, and discharge from the rectum (proctitis); sometimes there are no symptoms	Provide written information about sexually transmitted diseases; complete a thorough history and physical assessment; administer prescribed antibiotics; teach patient to refrain from sexual activity until course of antibiotics is completed; explain that it may be necessary to have repeat testing 3 mo after initial treatment to assess for re-infection from sexual partner

PRETEST:

- ♦ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ♦ **Patient Teaching:** Inform the patient this test can assist in diagnosing chlamydial infection.
- ♦ Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's immune and reproductive systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 10 days to monitor a change in titer.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform that patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
 - ▶ Recognize anxiety related to test results, and be supportive. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Educate the patient regarding access to counseling services.
 - ▶ **Social and Cultural Considerations:** Counsel the patient, as appropriate, as to the risk of sexual transmission and educate the patient regarding proper prophylaxis. Reinforce the importance of strict adherence to the treatment regimen.
 - ▶ **Social and Cultural Considerations:** Inform the patient with positive *C. trachomatis* that findings must be reported to a local health department official, who will question the patient regarding his or her sexual partners.
 - ▶ **Social and Cultural Considerations:** Offer support, as appropriate, to patients who may be the victim of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, non-threatening atmosphere for a discussion during which you explain the risks of sexually transmitted diseases. It is also important to discuss emotions the patient may experience (guilt, depression, anger) as a victim of rape or sexual assault.
 - ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.
- Patient Education:**
- ▶ Provide emotional support if the patient is pregnant and if results are positive.

- ▶ Inform the patient that chlamydial infection during pregnancy places the newborn at risk for pneumonia and conjunctivitis.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:**Knowledge**

- ▶ States understanding of the importance of increasing fluid intake to thin and mobilize secretions
- ▶ States understanding of completing course of antibiotics for chlamydial

infection prior to engaging in sexual activity.

Skills

- ▶ Demonstrates proficiency with cough and deep breathing
- ▶ Demonstrates proficient use of incentive spirometer

Attitude

- ▶ Complies with the request to complete retesting for chlamydial infection in 3 mo.

RELATED MONOGRAPHS:

- ▶ Related tests include culture bacterial (anal, genital), culture viral, Gram stain, Pap smear, and syphilis serology.
- ▶ Refer to the Immune and Reproductive systems tables at the end of the book for related tests by body system.

Chloride, Blood

SYNONYM/ACRONYM: Cl⁻.

COMMON USE: To evaluate electrolytes, acid-base balance, and hydration level.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Ion-selective electrode)

Age	Conventional & SI Units
Premature	95–110 mEq/L or mmol/L
0–1 mo	98–113 mEq/L or mmol/L
2 mo–older adult	97–107 mEq/L or mmol/L

DESCRIPTION: Chloride is the most abundant anion in the extracellular fluid. Its most important function is in the maintenance of acid-base balance, in which it competes with

bicarbonate for sodium. Chloride levels generally increase and decrease proportionally to sodium levels and inversely proportional to bicarbonate levels. Chloride also participates with sodium in the maintenance of water balance and aids in the regulation of osmotic pressure. Chloride contributes to gastric acid (hydrochloric acid) for digestion and activation of enzymes. The chloride content of venous blood is slightly higher than that of arterial blood because chloride ions enter red blood cells

in response to absorption of carbon dioxide into the cell. As carbon dioxide enters the blood cell, bicarbonate leaves and chloride is absorbed in exchange to maintain electrical neutrality within the cell.

Chloride is provided by dietary intake, mostly in the form of sodium chloride. It is absorbed by the gastrointestinal system, filtered out by the glomeruli, and reabsorbed by the renal tubules. Excess chloride is excreted in the urine. Serum values normally remain fairly stable. A slight decrease may be detectable after meals because chloride is used to produce hydrochloric acid as part of the digestive process. Measurement of chloride levels is not as essential as measurement of other electrolytes such as sodium or potassium. Chloride is usually included in standard electrolyte panels to detect the presence of unmeasured anions via calculation of the anion gap. Chloride levels are usually not interpreted apart from sodium, potassium, carbon dioxide, and anion gap.

The patient's clinical picture needs to be considered in the evaluation of electrolytes. Fluid and electrolyte imbalances are often seen in patients with serious illness or injury because in these cases the clinical situation has affected the normal homeostatic balance of the body. It is also possible that therapeutic treatments being administered are causing or contributing to the electrolyte imbalance. Children and adults are at high risk for fluid and electrolyte imbalances when chloride levels are depleted. Children are considered to be at high risk during chloride imbalance because a positive serum

chloride balance is important for expansion of the extracellular fluid compartment. Anemia, the result of decreased hemoglobin levels, is a frequent issue for elderly patients. Because hemoglobin participates in a major buffer system in the body, depleted hemoglobin levels affect the efficiency of chloride ion exchange for bicarbonate in red blood cells, which in turn affects acid-base balance. Elderly patients are also at high risk because their renal response to change in pH is slower, resulting in a more rapid development of electrolyte imbalance.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in confirming a diagnosis of disorders associated with abnormal chloride values, as seen in acid-base and fluid imbalances
- Differentiate between types of acidosis (hyperchloremic versus anion gap)
- Monitor effectiveness of drug therapy to increase or decrease serum chloride levels

POTENTIAL DIAGNOSIS

Increased in

- Acute renal failure (*related to decreased renal excretion*)
- Cushing's disease (*related to sodium retention as a result of increased levels of aldosterone; typically, chloride levels follow sodium levels*)
- Dehydration (*related to hemoconcentration*)
- Diabetes insipidus (*hemoconcentration related to excessive urine production*)

- Excessive infusion of normal saline (*related to excessive intake*)
- Head trauma with hypothalamic stimulation or damage
- Hyperparathyroidism (primary) (*high chloride-to-phosphate ratio is used to assist in diagnosis*)
- Metabolic acidosis (*associated with prolonged diarrhea*)
- Renal tubular acidosis (*acidosis related to net retention of chloride ions*)
- Respiratory alkalosis (e.g., hyperventilation) (*related to metabolic exchange of intracellular chloride replaced by bicarbonate; chloride levels increase*)
- Salicylate intoxication (*related to acid-base imbalance resulting in a hyperchloremic acidosis*)
- Salt-losing nephritis (*related to excessive loss*)
- Syndrome of inappropriate antidiuretic hormone secretion (*related to dilutional effect*)
- Water intoxication (*related to dilutional effect*)

CRITICAL FINDINGS

- Less than 80 mEq/L or mmol/L (SI: Less than 80 mmol/L)
- Greater than 115 mEq/L or mmol/L (SI: Greater than 115 mEq/L or mmol/L)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

The following may be seen in hypochloremia: twitching or tremors, which may indicate excitability of the

Decreased in

- Addison's disease (*related to insufficient production of aldosterone; potassium is retained while sodium and chloride are lost*)
- Burns (*dilutional effect related to sequestration of extracellular fluid*)
- Congestive heart failure (*related to dilutional effect of fluid buildup*)
- Diabetic ketoacidosis (*related to acid-base imbalance with accumulation of ketone bodies and increased chloride*)
- Excessive sweating (*related to excessive loss of chloride without replacement*)
- Gastrointestinal loss from vomiting (severe), diarrhea, nasogastric suction, or fistula
- Metabolic alkalosis (*related to homeostatic response in which intracellular chloride increases to reduce alkalinity of extracellular fluid*)
- Overhydration (*related to dilutional effect*)
- Respiratory acidosis (chronic)

nervous system; slow and shallow breathing; and decreased blood pressure as a result of fluid loss. Possible interventions relate to treatment of the underlying cause.

Signs and symptoms associated with hyperchloremia are weakness; lethargy; and deep, rapid breathing. Proper interventions include treatments that correct the underlying cause.

INTERFERING FACTORS

- Drugs that may cause an increase in chloride levels include acetazolamide, acetylsalicylic acid, ammonium chloride, androgens, bromide, chlorothiazide, cholestyramine, cyclosporine, estrogens, guanethidine, hydrochlorothiazide, lithium, methyl-dopa, NSAIDs, oxyphenbutazone, phenylbutazone, and triamterene.
- Drugs that may cause a decrease in chloride levels include aldosterone, bicarbonate, corticosteroids, corticotropin, cortisone, diuretics, ethacrynic acid, furosemide, hydroflumethiazide, laxatives (if chronic abuse occurs), mannitol, meralluride, mersalyl, methyclothiazide, metolazone, and triamterene. Many of these drugs can cause a diuretic action that inhibits the tubular reabsorption of chloride. *Note:* Triamterene has nephrotoxic and azotemic effects, and when organ damage has occurred, increased serum chloride levels result. Potassium chloride (found in salt substitutes) can lower blood chloride levels and raise urine chloride levels.
- Elevated triglyceride or protein levels may cause a volume-displacement error in the specimen, reflecting falsely decreased chloride values when chloride measurement methods employing predilution specimens are used (e.g., indirect ion-selective electrode, flame photometry).

- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the normal saline contained in the IV solution, falsely increasing the result.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating the amount of chloride in the blood.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, endocrine, gastrointestinal, genitourinary, and respiratory systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Specimens should not be collected during hemodialysis.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement. Instruct the patient not to clench and unclench fist immediately before or during specimen collection.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe the patient on saline IV fluid replacement therapy for signs of overhydration, especially in cases in which there is a history of cardiac or renal disease. Signs of overhydration include constant, irritable cough; chest rales; dyspnea; or engorgement of neck and hand veins.
- ▶ Evaluate the patient for signs and symptoms of dehydration. Check the patient's skin turgor, mucous membrane moisture, and ability to produce tears. Dehydration is a significant and common finding in geriatric and other patients in whom renal function has deteriorated.
- ▶ Monitor daily weights as well as intake and output to determine whether fluid retention is occurring because of sodium and chloride excess. Patients at risk for or with a history of fluid imbalance are also at risk for electrolyte imbalance.
- ▶ **Nutritional Considerations:** Careful observation of the patient on IV fluid

replacement therapy is important. A patient receiving a continuous 5% dextrose solution (D₅W) may not be taking in an adequate amount of chloride to meet the body's needs. The patient, if allowed, should be encouraged to drink fluids such as broths, tomato juice, or colas and to eat foods such as meats, seafood, or eggs, which contain sodium and chloride. The use of table salt may also be appropriate.

- ▶ **Nutritional Considerations:** Instruct patients with elevated chloride levels to avoid eating or drinking anything containing sodium chloride salt. The patient or caregiver should also be encouraged to read food labels to determine which products are suitable for a low-sodium diet.
- ▶ **Nutritional Considerations:** Instruct patients with low chloride levels that a decrease in iron absorption may occur as a result of less chloride available to form gastric acid, which is essential for iron absorption. In prolonged periods of chloride deficit, iron-deficiency anemia could develop.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Educate the patient regarding access to nutritional counseling services. Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, anion gap, blood gases, carbon dioxide, CBC hematocrit, CBC hemoglobin, osmolality, potassium, protein total and fractions, sodium, and US abdomen.
- ▶ Refer to the Cardiovascular, Endocrine, Gastrointestinal, Genitourinary, and Respiratory systems tables at the end of the book for related test by body system.

Chloride, Sweat

SYNONYM/ACRONYM: Sweat test, pilocarpine iontophoresis sweat test, sweat chloride.

COMMON USE: To assist in diagnosing cystic fibrosis.

SPECIMEN: Sweat (0.1 mL minimum) collected by pilocarpine iontophoresis.

NORMAL FINDINGS: (Method: Ion-specific electrode or titration)

	Conventional & SI Units
Normal	0–40 mEq/L or mmol/L
Borderline	41–60 mEq/L or mmol/L
Consistent with the diagnosis of CF	Greater than 60 mEq/L or mmol/L

DESCRIPTION: Cystic fibrosis (CF) is a genetic disease that affects normal functioning of the exocrine glands, causing them to excrete large amounts of electrolytes. Patients with CF have sweat electrolyte levels two to five times normal. Sweat test values, with family history and signs and symptoms, are required to establish a diagnosis of CF. CF is transmitted as an autosomal recessive trait and is characterized by abnormal exocrine secretions within the lungs, pancreas, small intestine, bile ducts, and skin. Clinical presentation may include chronic problems of the gastrointestinal and/or respiratory system. CF is more common in Caucasians. Sweat conductivity is a screening method that estimates chloride levels. Sweat conductivity values greater than or equal to 50 mmol/L should be referred for quantitative analysis of sweat chloride. Testing of stool samples for decreased trypsin activity has been used as a screen for CF in infants and

children, but this is a much less reliable method than the sweat test. The American College of Obstetricians and Gynecologists (ACOG) suggests that carrier screening be discussed as an option to patients (and couples) who are pregnant or are considering pregnancy. Laboratories generally offer a panel of the current and most common cystic fibrosis mutations recommended by ACOG and the American College of Medical Genetics. Some states include CF in the neonatal screening performed at birth. Genetic testing can also be reliably performed on DNA material harvested from whole blood, amniotic fluid (submitted with maternal blood sample), chorionic villus samples (submitted with maternal blood sample), or buccal swabs to screen for genetic mutations associated with CF and can assist in confirming a diagnosis of CF, but the sweat electrolyte test is still considered the gold standard diagnostic for CF.

The sweat test is a noninvasive study done to assist in the diagnosis of CF when considered with other test results and physical assessments. This test is usually performed on children, although adults may also be tested; it is not usually ordered on adults because results can be highly variable and should be interpreted with caution. Sweat for specimen collection is induced by a small electrical current carrying the drug pilocarpine. The test measures the concentration of chloride produced by the sweat glands of the skin. A high concentration of chloride in the specimen indicates the presence of CF. The sweat test is used less commonly to measure the concentration of sodium ions for the same purpose.

This procedure is contraindicated for

-  Patients with skin disorders (e.g., rash, erythema, eczema).

INDICATIONS

- Assist in the diagnosis of CF
- Screen for CF in individuals with a family history of the disease
- Screen for suspected CF in children with recurring respiratory infections
- Screen for suspected CF in infants with failure to thrive and infants who pass meconium late
- Screen for suspected CF in individuals with malabsorption syndrome

POTENTIAL DIAGNOSIS

Increased in
Conditions that affect electrolyte distribution and excretion may produce false-positive sweat test results.

- Addison's disease
- Alcoholic pancreatitis (***dysfunction of CF gene is linked to pancreatic disease susceptibility***)
- CF
- Chronic pulmonary infections (***related to undiagnosed CF***)
- Congenital adrenal hyperplasia
- Diabetes insipidus
- Familial cholestasis
- Familial hypoparathyroidism
- Fucosidosis
- Glucose-6-phosphate dehydrogenase deficiency
- Hypothyroidism
- Mucopolysaccharidosis
- Nephrogenic diabetes insipidus
- Renal failure

Decreased in
Conditions that affect electrolyte distribution and retention may produce false-negative sweat test results.

- Edema
- Hypoaldosteronism
- Hypoproteinemia
- Sodium depletion

CRITICAL FINDINGS 

- 20 yr or younger: greater than 60 mEq/L or mmol/L (SI greater than 60 mEq/L) considered diagnostic of CF
- Older than 20 years: greater than 70 mEq/L or mmol/L (SI greater than 70 mEq/L) considered diagnostic of CF

Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms. Values should be interpreted with consideration of family history and clinical signs and symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

The validity of the test result is affected tremendously by proper specimen collection and handling. Before proceeding with appropriate patient education and counseling, it is important to perform duplicate testing on patients whose results are in the diagnostic or intermediate ranges. A negative test should be repeated if test results do not support the clinical picture.

INTERFERING FACTORS

- An inadequate amount of sweat may produce inaccurate results.
- Improper cleaning of the skin or improper application of gauze pad or filter paper for collection affects test results.
- Hot environmental temperatures may reduce the sodium chloride concentration in sweat; cool environmental temperatures may reduce the amount of sweat collected.

- If the specimen container that stores the gauze or filter paper is handled without gloves, the test results may show a false increase in the final weight of the collection container.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing an inherited disease that affects the lungs.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and respiratory systems, especially failure to thrive or CF in other family members, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient and caregiver. Encourage the caregiver to stay with and support the child during the test. The iontophoresis and specimen collection usually takes approximately 75 to 90 min. Address concerns about pain and explain that there is no pain associated with the test, but a stinging sensation may be experienced when the low electrical current is applied at the site.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶  The test should not be performed if the patient is receiving oxygen by means of an open system related to the remote possibility of explosion from an electrical spark. If the patient can temporarily receive oxygen via a face-mask or nasal cannula, then sweat testing can be done.
- ▶  The patient is placed in a position that will allow exposure of the site on the forearm or thigh. To ensure collection of an adequate amount of sweat in a small infant, two sites (right forearm and right thigh) can be used. The patient should be covered to prevent cool environmental temperatures from affecting sweat production. The site selected for iontophoresis should never be the chest or left side because of the risk of cardiac arrest from the electrical current.
- ▶ The site is washed with distilled water and dried. A positive electrode is attached to the site on the right forearm or right thigh and covered with a pad that is saturated with pilocarpine, a drug that stimulates sweating. A negative electrode is covered with a pad that is saturated with bicarbonate solution. Iontophoresis is achieved by supplying a low (4 to 5 mA) electrical current via the electrode for 12 to 15 min. Battery-powered equipment is preferred over an electrical outlet to supply the current.
- ▶ The electrodes are removed, revealing a red area at the site, and the site is washed with distilled water and dried to remove any possible contaminants on the skin.

- ▶ Preweighed disks made of filter paper are placed on the site with a forceps; to prevent evaporation of sweat collected at the site, the disks are covered with paraffin or plastic and sealed at the edges. The disks are left in place for about 1 hr. Distract the child with books or games to allay fears.
- ▶ After 1 hr, the paraffin covering is removed, and disks are placed in a preweighed container with a forceps. Use gloves to handle the specimen container; do not directly handle the preweighed specimen container or filter paper. The container is sealed and sent immediately to the laboratory for weighing and analysis of chloride content. At least 100 mg of sweat is required for accurate results.
- ▶ Terminate the test if the patient complains of burning at the electrode site. Reposition the electrode before the test is resumed.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. Do not directly handle the preweighed specimen container or filter paper.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient/caregiver.
- ▶ Observe/assess the site for unusual color, sensation, or discomfort.
- ▶ Inform the patient and caregiver that redness at the site fades in 2 to 3 hr.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ **Nutritional Considerations:** If appropriate, instruct the patient and caregiver that nutrition may be altered because of impaired digestive processes associated with CF. Increased viscosity of exocrine gland secretion may lead to poor absorption of digestive enzymes and fat-soluble vitamins, necessitating oral intake of digestive enzymes with each meal and calcium and vitamin (A, D, E, and K) supplementation. Malnutrition also is seen commonly in patients with chronic, severe respiratory disease for many reasons, including fatigue, lack of appetite, and gastrointestinal distress. Research has

estimated that the daily caloric intake needed for children with CF between 4 and 7 yr may be 2,000 to 2,800 and for teens 3,000 to 5,000. Tube feeding may be necessary to supplement regular high-calorie meals. To prevent pulmonary infection and decrease the extent of lung tissue damage, adequate intake of vitamins A and C is also important. Excessive loss of sodium chloride through the sweat glands of a patient with CF may necessitate increased salt intake, especially in environments where increased sweating is induced. The importance of following the prescribed diet should be stressed to the patient and caregiver.

- ▶ If appropriate, instruct the patient and caregiver that ineffective airway clearance related to excessive production of mucus and decreased ciliary action may result. Chest physical therapy and the use of aerosolized antibiotics and mucus-thinning drugs are an important part of the daily treatment regimen.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Help the patient and caregiver to cope with

long-term implications. Recognize that anticipatory anxiety and grief related to potential lifestyle changes may be expressed when someone is faced with a chronic disorder. Provide information regarding genetic counseling and possible screening of other family members if appropriate. Provide contact information, if desired, for the Cystic Fibrosis Foundation (www.cff.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain that a positive sweat test alone is not diagnostic of CF; repetition of borderline and positive tests is generally recommended. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include α_1 -antitrypsin/phenotype, amylase, anion gap, biopsy chorionic villus, blood gases, fecal analysis, fecal fat, newborn screening, osmolality, phosphorus, potassium, and sodium.
- ▶ Refer to the Endocrine and Respiratory systems tables at the end of the book for related tests by body system.

Cholangiography, Percutaneous Transhepatic

SYNONYM/ACRONYM: Percutaneous cholecystogram, PTC, PTHC.

COMMON USE: To visualize and assess biliary ducts for causes of obstruction and jaundice, such as cancer or stones.

AREA OF APPLICATION: Biliary system.

CONTRAST: Radiopaque iodine-based contrast medium.

DESCRIPTION: Percutaneous transhepatic cholangiography (PTC) is a test used to visualize the biliary system in order to evaluate persistent upper abdominal pain after cholecystectomy and to determine the presence and cause of obstructive jaundice. The liver is punctured with a thin needle under fluoroscopic guidance, and contrast medium is injected as the needle is slowly withdrawn. This test visualizes the biliary ducts without depending on the gallbladder's concentrating ability. The intrahepatic and extrahepatic biliary ducts, and occasionally the gallbladder, can be visualized to determine possible obstruction. In obstruction of the extrahepatic ducts, a catheter can be placed in the duct to allow external drainage of bile. Endoscopic retrograde cholangiopancreatography (ERCP) and PTC are the only methods available to view the biliary tree in the presence of jaundice. ERCP poses less risk and is probably done more often.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic

because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of non-ionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
- ◆ Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**
- ◆ Patients with cholangitis; **the injection of the contrast medium can increase biliary pressure, leading to bacteremia, septicemia, and shock.**

INDICATIONS

- Aid in the diagnosis of obstruction caused by gallstones, benign strictures, malignant tumors, congenital cysts, and anatomic variations
- Determine the cause, extent, and location of mechanical obstruction

- Determine the cause of upper abdominal pain after cholecystectomy
- Distinguish between obstructive and nonobstructive jaundice

POTENTIAL DIAGNOSIS

Normal findings in

- Biliary ducts are normal in diameter, with no evidence of dilation, filling defects, duct narrowing, or extravasation.
- Contrast medium fills the ducts and flows freely.
- Gallbladder appears normal in size and shape.

Abnormal findings in

- Anatomic biliary or pancreatic duct variations
- Biliary sclerosis
- Cholangiocarcinoma
- Cirrhosis
- Common bile duct cysts
- Gallbladder carcinoma
- Gallstones
- Hepatitis
- Nonobstructive jaundice
- Pancreatitis
- Sclerosing cholangitis
- Tumors, strictures, inflammation, or gallstones of the common bile duct

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field, which may inhibit organ visualization and cause unclear images.

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the bile ducts of the gallbladder and pancreas.

- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's gastrointestinal and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that this procedure is performed before an upper GI study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note time and date of last dose.
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in the radiology department by an HCP, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, antibiotics, anesthetics, sedatives, or emergency medications. Patients who will undergo percutaneous bile drainage may have infected bile and as such should have an antibiotic administered at least 1 hr before the procedure in order to avoid spreading the infection to other parts of the body. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.
- ▶ Type and screen the patient's blood for possible transfusion.
- ▶ Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure depending on the institution's policy.
- ▶ Instruct the patient to remove all external metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

PTC is an invasive procedure and has potential risks that include allergic reaction **related to contrast reaction**, bleeding, septicemia, bile peritonitis, and extravasation of the contrast medium.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Assess for completion of bowel preparation according to the institution's procedure.

- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure. Use nonionic contrast medium for the procedure if the patient has a history of allergic reactions to any relevant substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Place the patient in the supine position on an examination table.
- ▶ A kidney, ureter, and bladder (KUB) or plain film is taken to ensure that no barium or stool will obscure visualization of the biliary system.
- ▶ An area over the abdominal wall is anesthetized, and the needle is inserted and advanced under fluoroscopic guidance. Contrast medium is injected when placement is confirmed by the free flow of bile.
- ▶ A specimen of bile may be sent to the laboratory for culture and cytological analysis.
- ▶ At the end of the procedure, the contrast medium is aspirated from the biliary ducts, relieving pressure on the dilated ducts.
- ▶ If an obstruction is found during the procedure, a catheter is inserted into the bile duct to allow drainage of bile.
- ▶ Maintain pressure over the needle insertion site for several hours if bleeding is persistent.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.
- ▶ Establish a closed and sterile drainage system if a catheter is left in place.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is restarted.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the puncture site for signs of bleeding, hematoma formation, ecchymosis, or leakage of bile. Notify the HCP if any of these is present.
- ▶ Advise the patient to watch for symptoms of infection, such as pain, fever, increased pulse rate, and muscle aches.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, amylase, AMA, AST, biopsy liver, cancer antigens, cholangiography postoperative,

cholangiopancreatography endoscopic retrograde, CT abdomen, GGT, hepatitis antigens and antibodies (A, B, C), hepatobiliary scan, KUB studies, laparoscopy abdominal, lipase, MRI abdomen, peritoneal fluid analysis,

pleural fluid analysis, and US liver and biliary tract.

- Refer to the Gastrointestinal and Hepatobiliary systems tables at the end of the book for related tests by body system.

C

Cholangiography, Postoperative

SYNONYM/ACRONYM: T-tube cholangiography.

COMMON USE: A postoperative evaluation to provide ongoing assessment of the effectiveness of bile duct or gall bladder surgery.

AREA OF APPLICATION: Gallbladder, bile ducts.

CONTRAST: Iodinated contrast medium.

DESCRIPTION: After cholecystectomy, a self-retaining, T-shaped tube may be inserted into the common bile duct. Postoperative (T-tube) cholangiography is a fluoroscopic and radiographic examination of the biliary tract that involves the injection of a contrast medium through the T-tube inserted during surgery. This test may be performed during surgery and again 5 to 10 days after cholecystectomy to assess the patency of the common bile duct and to detect any remaining calculi. The procedure will also help identify areas of stenosis or the presence of fistulae (as a result of the surgery). T-tube placement may also be done after a liver transplant because biliary duct obstruction or anastomotic leakage is possible. This test should be performed before any gastrointestinal (GI) studies using barium and after any studies involving the measurement of iodinated compounds.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit

from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic**
-  Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure**
-  Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding**
-  Patients with cholangitis; **the injection of the contrast medium can increase biliary pressure, leading to bacteremia, septicemia, and shock**
-  Patients with acute cholecystitis or severe liver disease; **the procedure may worsen the condition**

INDICATIONS

- Determine biliary duct patency before T-tube removal
- Identify the cause, extent, and location of obstruction after surgery

POTENTIAL DIAGNOSIS

Normal findings in

- Biliary ducts are normal in size.
- Contrast medium fills the ductal system and flows freely.

Abnormal findings in

- Appearance of channels of contrast medium outside of the biliary ducts, indicating a fistula
- Filling defects, dilation, or radiolucent shadows within the biliary ducts, indicating calculi or neoplasm

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Air bubbles resembling calculi may be seen if there is inadvertent injection of air.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are

not adjusted for their small size.

Pediatric Considerations

Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their radiation level.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the bile ducts of the gallbladder and pancreas.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of results of the patient's gastrointestinal and hepatobiliary systems, symptoms, and previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that this procedure is performed before an upper GI study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in the radiology department by an HCP and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected through the t-tube that was left in place.
- ▶ Instruct the patient to remove jewelry and other metallic objects in the area to be examined.
- ▶ Note that there are no food or fluid restrictions for a post-surgical study but the patient should follow the standard pre-operative restrictions on food and fluids for 8 hr prior to an operative cholangiogram. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Cholangiography and establishing an IV site are invasive procedures and have potential risks that include allergic reaction **related to contrast reaction,**

bleeding, septicemia, bile peritonitis, and extravasation of the contrast medium.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any relevant substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Clamp the T-tube 24 hr before and during the procedure, if ordered, to help prevent air bubbles from entering the ducts.
- ▶ An x-ray of the abdomen is obtained to determine if any residual contrast medium is present from previous studies.
- ▶ The patient is placed on an examination table in the supine position.
- ▶ The area around the T-tube is draped; the end of the T-tube is cleansed with 70% alcohol. If the T-tube site is inflamed and painful, a local anesthetic (e.g., lidocaine) may be injected around the site. A needle is inserted into the open end of the T-tube, and the clamp is removed.

- ▶ Contrast medium is injected, and fluoroscopy is performed to visualize contrast medium moving through the duct system.
- ▶ The patient may feel a bloating sensation in the upper right quadrant as the contrast medium is injected. The tube is clamped, and images are taken. A delayed image may be taken 15 min later to visualize passage of the contrast medium into the duodenum.
- ▶ For procedures done after surgery, the T-tube is removed if findings are normal; a dry, sterile dressing is applied to the site.
- ▶ If retained calculi are identified, the T-tube is left in place for 4 to 6 wk until the tract surrounding the T-tube is healed to perform a percutaneous removal.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Monitor T-tube site and change sterile dressing, as ordered.
- ▶ Instruct the patient on the care of the site and dressing changes.
- ▶ Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Carefully monitor the patient for fatigue and fluid and electrolyte imbalance.

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor pro-

gression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CT abdomen, hepatobiliary scan, KUB, MRI abdomen, and US liver and biliary system.
- ▶ Refer to the Gastrointestinal and Hepatobiliary systems tables at the end of the book for tests by related body systems.

Cholangiopancreatography, Endoscopic Retrograde

SYNONYM/ACRONYM: ERCP.

COMMON USE: To visualize and assess the pancreas and common bile ducts for occlusion or stricture.

AREA OF APPLICATION: Gallbladder, bile ducts, pancreatic ducts.

CONTRAST: Iodinated contrast medium.

DESCRIPTION: Endoscopic retrograde cholangiopancreatography (ERCP) allows direct visualization of the pancreatic and biliary ducts with a flexible endoscope and, after injection of contrast material, with x-rays. It allows the health-care provider (HCP) performing the procedure to view the pancreatic, hepatic, and common bile ducts and the ampulla of Vater. ERCP and percutaneous transhepatic cholangiography (PTC) are the only procedures that allow direct visualization of the biliary and pancreatic ducts. ERCP is less invasive and has less morbidity than PTC. It is useful in the

evaluation of patients with jaundice, because the ducts can be visualized even when the patient's bilirubin level is high. (In contrast, oral cholecystography and IV cholangiography cannot visualize the biliary system when the patient has high bilirubin levels.) With endoscopy, the distal end of the common bile duct can be widened, and gallstones can be removed and stents placed in narrowed bile ducts to allow bile to be drained in jaundiced patients. During the endoscopic procedure, specimens of suspicious tissue can be taken for pathological review, and manometry pressure readings

can be obtained from the bile and pancreatic ducts. ERCP is used in the diagnosis and follow-up of pancreatic disease; it can also be used therapeutically to remove small lesions called choleliths, perform sphincterotomy (biliary or pancreatic repair for stenosis), perform stent placement, repair stenosis using dilation balloons, or accomplish the extraction of stones using dilation balloons.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure**
- ◆ Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding**
- ◆ Patients with an acute infection of the biliary system, pharyngeal or esophageal obstruction (e.g., Zenker's diverticulum), or possible pseudocyst of the pancreas

INDICATIONS

- Assess jaundice of unknown cause to differentiate biliary tract obstruction from liver disease
- Collect specimens for cytology
- Identify obstruction caused by calculi, cysts, ducts, strictures, stenosis, and anatomic abnormalities
- Retrieve calculi from the distal common bile duct and release strictures
- Perform therapeutic procedures, such as sphincterotomy and placement of biliary drains

POTENTIAL DIAGNOSIS

Normal findings in

- Normal appearance of the duodenal papilla
- Patency of the pancreatic and common bile ducts

Abnormal findings

- Duodenal papilla tumors
- Pancreatic cancer
- Pancreatic fibrosis
- Pancreatitis
- Sclerosing cholangitis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Previous surgery involving the stomach or duodenum, which can make locating the duodenal papilla difficult.
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- A patient with unstable cardiopulmonary status, blood coagulation defects, or cholangitis (test may have to be rescheduled unless the patient received antibiotic therapy before the test).
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Considerations** Information on the Image Gently Campaign can be found at the

Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the bile ducts of the gallbladder and pancreas.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's gastrointestinal and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that this procedure is performed before an upper GI study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued

on the day of the test and continue to be withheld for 48 hr after the test.

Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**

- ▶ Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a GI lab or radiology department, usually by an HCP, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected at a separate site from the IV line.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Cholangiography is an invasive procedure and has potential risks that include allergic reaction **related to contrast reaction**, bleeding, septicemia, pancreatitis, and bowel perforation.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient

demographics, initials of the person collecting the specimen, date, and time of collection.

- ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Assess for completion of bowel preparation according to the institution's procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any relevant substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer ordered sedation.
- ▶ An x-ray of the abdomen is obtained to determine if any residual contrast medium is present from previous studies.
- ▶ The oropharynx is sprayed or swabbed with a topical local anesthetic.
- ▶ The patient is placed on an examination table in the left lateral position with the left arm behind the back and right hand at the side with the neck slightly flexed. A protective guard is inserted into the mouth to cover the teeth. A bite block can also be inserted to maintain adequate opening of the mouth.
- ▶ The endoscope is passed through the mouth with a dental suction device in

place to drain secretions. A side-viewing flexible fiberoptic endoscope is passed into the duodenum, and a small cannula is inserted into the duodenal papilla (ampulla of Vater).

- ▶ The patient is placed in the prone position. The duodenal papilla is visualized and cannulated with a catheter. Occasionally the patient can be turned slightly to the right side to aid in visualization of the papilla.
- ▶ IV glucagon or anticholinergics can be administered to minimize duodenal spasm and to facilitate visualization of the ampulla of Vater.
- ▶ ERCP manometry can be done at this time to measure the pressure in the bile duct, pancreatic duct, and sphincter of Oddi at the papilla area via the catheter as it is placed in the area before the contrast medium is injected.
- ▶ When the catheter is in place, contrast medium is injected into the pancreatic and biliary ducts via the catheter, and fluoroscopic images are taken. Biopsy specimens for cytological analysis may be obtained.
- ▶ Place specimens in appropriate containers, label them properly, and promptly transport them to the laboratory.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Do not allow the patient to eat or drink until the gag reflex returns, after which the patient is permitted to eat lightly for 12 to 24 hr.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity after 24 hr, or as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline

values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Tell the patient to expect some throat soreness and possible hoarseness. Advise the patient to use warm gargles, lozenges, ice packs to the neck, or cool fluids to alleviate throat discomfort.
- ▶ Inform the patient that any belching, bloating, or flatulence is the result of air insufflation.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include amylase, CT abdomen, hepatobiliary scan, KUB studies, lipase, MRI abdomen, peritoneal fluid analysis, pleural fluid analysis, and US liver and biliary system.
- ▶ Refer to the Gastrointestinal and Hepatobiliary systems tables at the end of the book for related tests by body system.

Cholesterol, HDL and LDL

SYNONYM/ACRONYM: α_1 -Lipoprotein cholesterol, high-density cholesterol, HDLC, and β -lipoprotein cholesterol, low-density cholesterol, LDLC.

COMMON USE: To assess risk and monitor for coronary artery disease.

SPECIMEN: Serum (2 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Spectrophotometry)

HDLC	Conventional Units	SI Units (Conventional Units \times 0.0259)
Birth Children, adults, and older adults	6–56 mg/dL	0.16–1.45 mmol/L
Desirable	Greater than 60 mg/dL	Greater than 1.55 mmol/L
Acceptable	40–60 mg/dL	1–1.55 mmol/L
Low	Less than 40 mg/dL	Less than 1 mmol/L

LDLC	Conventional Units	SI Units (Conventional Units \times 0.0259)
Optimal	Less than 100 mg/dL	Less than 2.59 mmol/L
Near optimal	100–129 mg/dL	2.59–3.34 mmol/L
Borderline high	130–159 mg/dL	3.37–4.11 mmol/L
High	160–189 mg/dL	4.14–4.9 mmol/L
Very high	Greater than 190 mg/dL	Greater than 4.92 mmol/L

	NMR LDLC Particle Number	NMR LDLC Small Particle Size
High-risk CAD	Less than 1,000 nmol/L	Less than 850 nmol/L
Moderately high-risk CAD	Less than 1,300 nmol/L	Less than 850 nmol/L

CAD, coronary artery disease; NMR, nuclear magnetic resonance.

DESCRIPTION: High-density lipoprotein cholesterol (HDLC) and low-density lipoprotein cholesterol (LDLC) are the major transport proteins for cholesterol in the body. It is believed that HDLC may have protective properties in that its role

includes transporting cholesterol from the arteries to the liver. LDLC is the major transport protein for cholesterol to the arteries from the liver. LDLC can be calculated using total cholesterol, total triglycerides, and HDLC levels. Beyond the total

cholesterol, HDL and LDL cholesterol values, other important risk factors must be considered. In November 2013, new guidelines for the prevention of cardiovascular disease (CVD) were developed by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with members of the National Heart, Lung, and Blood Institute's (NHLBI) ATP IV Expert Panel. The updated, evidence-based guidelines redefine the condition of concern as atherosclerotic cardiovascular disease (ASCVD) and expand ASCVD to include CVD, stroke, and peripheral artery disease. Some of the important highlights include the following:

- Movement away from the use of LDL cholesterol targets in determining treatment with statins. Recommendations that focus on selecting (a) the patients that fall into four groups most likely to benefit from statin therapy, and (b) the level of statin intensity most likely to affect or reduce development of ASCVD.
- Development of a new 10-yr risk assessment tool based on findings from a large, diverse population. Evidence-based risk factors include age, sex, ethnicity, total cholesterol, HDLC, blood pressure, blood-pressure treatment status, diabetes, and current use of tobacco products.
- Recommendations for aspects of lifestyle that would encourage prevention of ASCVD to include adherence to a Mediterranean-style or DASH (Dietary Approaches to Stop Hypertension)-style diet; dietary restriction of saturated fats, trans fats, sugar, and sodium; and regular participation in aerobic exercise. The guidelines

contain reductions in body mass index (BMI) cutoffs for men and women designed to promote discussions between HCPs and their patients regarding the benefits of maintaining a healthy weight.

- Recognition that additional biological markers, such as family history, high-sensitivity C-reactive protein, ankle-brachial index (ABI), and coronary artery calcium (CAC) score, may be selectively used with the assessment tool to assist in predicting and evaluating risk.
- Recognition that other biomarkers such as apolipoprotein B, eGFR, creatinine, lipoprotein (a) or Lp(a), and microalbumin warrant further study and may be considered for inclusion in future guidelines.

Studies have shown that CAD is inversely related to LDLC particle number and size. The nuclear magnetic resonance (NMR) lipid profile uses NMR imaging spectroscopy to determine LDLC particle number and size in addition to measurement of the traditional lipid markers.

HDLC levels less than 40 mg/dL in men and women represent a coronary risk factor. There is an inverse relationship between HDLC and risk of CAD (i.e., lower HDLC levels represent a higher risk of CAD). Levels of LDLC in terms of risk for CAD are directly proportional to risk and vary by age group. The LDLC can be estimated using the Friedewald formula:

$$\text{LDLC} = (\text{Total Cholesterol}) - (\text{HDLC}) - (\text{VLDLC})$$

Very-low-density lipoprotein cholesterol (VLDLC) is estimated by

dividing the triglycerides (conventional units) by 5. Triglycerides in SI units would be divided by 2.18 to estimate VLDLC. It is important to note that the formula is valid only if the triglycerides are less than 400 mg/dL or 4.52 mmol/L.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine the risk of cardiovascular disease
- Evaluate the response to dietary and drug therapy for hypercholesterolemia
- Investigate hypercholesterolemia in light of family history of cardiovascular disease

POTENTIAL DIAGNOSIS

Although the exact pathophysiology is unknown, cholesterol is required for many functions at the cellular and organ levels. Elevations of cholesterol are associated with conditions caused by an inherited defect in lipoprotein metabolism, liver disease, kidney disease, or a disorder of the endocrine system. Decreases in cholesterol levels are associated with conditions caused by enzyme deficiencies, malnutrition, malabsorption, liver disease, and sudden increased utilization.

HDLC increased in

- Alcoholism
- Biliary cirrhosis
- Chronic hepatitis
- Exercise
- Familial hyper- α -lipoproteinemia

HDLC decreased in

- Abetalipoproteinemia
- Cholestasis
- Chronic renal failure
- Fish-eye disease

- Genetic predisposition or enzyme/cofactor deficiency
- Hepatocellular disorders
- Hypertriglyceridemia
- Nephrotic syndrome
- Obesity
- Premature CAD
- Sedentary lifestyle
- Smoking
- Tangier's disease
- Syndrome X (metabolic syndrome)
- Uncontrolled diabetes

LDLC increased in

- Anorexia nervosa
- Chronic renal failure
- Corneal arcus
- Cushing's syndrome
- Diabetes
- Diet high in cholesterol and saturated fat
- Dysglobulinemias
- Hepatic disease
- Hepatic obstruction
- Hyperlipoproteinemia types IIA and IIB
- Hypothyroidism
- Nephrotic syndrome
- Porphyria
- Pregnancy
- Premature CAD
- Syndrome X (metabolic syndrome)
- Tendon and tuberous xanthomas

LDLC decreased in

- Acute stress (severe burns, illness)
- Chronic anemias
- Chronic pulmonary disease
- Genetic predisposition or enzyme/cofactor deficiency
- Hyperthyroidism
- Hypolipoproteinemia and abetalipoproteinemia
- Inflammatory joint disease
- Myeloma
- Reye's syndrome
- Severe hepatocellular destruction or disease
- Tangier disease

CRITICAL FINDINGS: N/A**INTERFERING FACTORS**

- Drugs that may increase HDLC levels include albuterol, anticonvulsants, cholestyramine, cimetidine, clofibrate and other fibric acid derivatives, estrogens, ethanol (moderate use), lovastatin, niacin, oral contraceptives, pindolol, pravastatin, prazosin, and simvastatin.
- Drugs that may decrease HDLC levels include acebutolol, atenolol, danazol, diuretics, etretinate, interferon, isotretinoin, linseed oil, metoprolol, neomycin, nonselective β -adrenergic blocking agents, probucol, progesterone, steroids, and thiazides.
- Drugs that may increase LDLC levels include androgens, catecholamines, chenodiol, cyclosporine, danazol, diuretics, etretinate, glucogenic corticosteroids, and progestins.
- Drugs that may decrease LDLC levels include aminosalicic acid, cholestyramine, colestipol, estrogens, fibric acid derivatives, interferon, lovastatin, neomycin, niacin, pravastatin, prazosin, probucol, simvastatin, terazosin, and thyroxine.
- Some of the drugs used to lower total cholesterol and LDLC or increase HDLC may cause liver damage.
- Grossly elevated triglyceride levels invalidate the Friedewald formula for mathematical estimation of LDLC; if the triglyceride level is greater than 400 mg/dL, the formula should not be used.
- Fasting before specimen collection is highly recommended. Ideally, the patient should be on a stable diet for 3 wk and fast for 12 hr before specimen collection.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with evaluation of cholesterol level.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system and results of previously performed laboratory tests and diagnostic and surgical procedures. The presence of other risk factors, such as family history of heart disease, smoking, obesity, diet, lack of physical activity, hypertension, diabetes, previous myocardial infarction, and previous vascular disease, should be investigated.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for 12 hr before specimen collection. Protocols may vary among facilities.
- ▶ Confirm with the requesting health-care provider (HCP) that the patient should withhold medications known to influence test results, and instruct the patient accordingly.
- ▶ Note that there are no fluid restrictions unless by medical direction.

INTRATEST:

- ▶ Ensure that the patient has complied with dietary and medication restrictions as well as other pretesting preparations; ensure that food has been

restricted for at least 12 hr prior to the procedure.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, and medications, as directed by the HCP.
- ▶ **Nutritional Considerations:** Decreased HDLC level and increased LDLC level may be associated with CAD. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are ele-

vated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the ACC and AHA in conjunction with the NHLBI recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed), along with fish and lean poultry. A similar dietary pattern known as the DASH diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

- ▶ Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- ▶ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor

progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▶ Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BNP, calcium (total and ionized), cholesterol total, CT cardiac

scoring, CRP, CK and isoenzymes, echocardiography, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, triglycerides, and troponin. ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Cholesterol, Total

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess and monitor risk for coronary artery disease.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable. It is important to use the same tube type when serial specimen collections are anticipated for consistency in testing.

NORMAL FINDINGS: (Method: Spectrophotometry)

Risk	Conventional Units	SI Units (Conventional Units × 0.0259)
Children and adolescents (less than 20 yr)		
Desirable	Less than 170 mg/dL	Less than 4.4 mmol/L
Borderline	170–199 mg/dL	4.4–5.2 mmol/L
High	Greater than 200 mg/dL	Greater than 5.2 mmol/L
Adults and older adults		
Desirable	Less than 200 mg/dL	Less than 5.2 mmol/L
Borderline	200–239 mg/dL	5.2–6.2 mmol/L
High	Greater than 240 mg/dL	Greater than 6.2 mmol/L

Plasma values may be 10% lower than serum values.

DESCRIPTION: Cholesterol is a lipid needed to form cell membranes, bile salts, adrenal corticosteroid hormones, and other hormones such as estrogen and the androgens.

Cholesterol is obtained from the diet and also synthesized in the body, mainly by the liver and intestinal mucosa. Very low cholesterol values, as are sometimes seen in

critically ill patients, can be as life-threatening as very high levels. According to the National Cholesterol Education Program, maintaining cholesterol levels less than 200 mg/dL significantly reduces the risk of coronary heart disease. Beyond the total cholesterol and high-density lipoprotein cholesterol (HDL) values, other important risk factors must be considered. Many myocardial infarctions occur even in patients whose cholesterol levels are considered to be within acceptable limits or who are in a moderate-risk category. The combination of risk factors and lipid values helps identify individuals at risk so that appropriate interventions can be taken. If the cholesterol level is greater than 200 mg/dL, repeat testing after a 12- to 24-hr fast is recommended.

In November 2013 new guidelines for the prevention of cardiovascular disease (CVD) were developed by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with members of the National Heart, Lung, and Blood Institute's (NHLBI) ATP IV Expert Panel. The updated, evidence-based guidelines redefine the condition of concern as atherosclerotic cardiovascular disease (ASCVD) and expand ASCVD to include CVD, stroke, and peripheral artery disease. Some of the important highlights include the following:

- Movement away from the use of LDL cholesterol targets in determining treatment with statins. Recommendations that focus on selecting (a) the patients who fall into four groups most likely to benefit from statin therapy, and (b) the level of statin intensity

most likely to affect or reduce development of ASCVD.

- Development of a new 10-yr risk assessment tool based on findings from a large, diverse population. Evidence-based risk factors include age, sex, ethnicity, total cholesterol, HDL, blood pressure, blood-pressure treatment status, diabetes, and current use of tobacco products.
- Recommendations for aspects of lifestyle that would encourage prevention of ASCVD include adherence to a Mediterranean or DASH (Dietary Approaches to Stop Hypertension) style diet; dietary restriction of saturated fats, trans fats, sugar, and sodium; and regular participation in aerobic exercise. The guidelines contain reductions in body mass index (BMI) cutoffs for men and women designed to promote discussions between health-care providers (HCPs) and their patients regarding the benefits of maintaining a healthy weight.
- Recognition that additional biological markers, such as family history, high-sensitivity C-reactive protein, ankle-brachial index (ABI), and coronary artery calcium (CAC) score, may be selectively used with the assessment tool to assist in predicting and evaluating risk.
- Recognition that other biomarkers such as apolipoprotein B, eGFR, creatinine, lipoprotein (a) or Lp(a), and microalbumin warrant further study and may be considered for inclusion in future guidelines.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in determining risk of cardiovascular disease

- Assist in the diagnosis of nephrotic syndrome, hepatic disease, pancreatitis, and thyroid disorders
- Evaluate the response to dietary and drug therapy for hypercholesterolemia
- Investigate hypercholesterolemia in light of family history of cardiovascular disease

POTENTIAL DIAGNOSIS

Increased in

Although the exact pathophysiology is unknown, cholesterol is required for many functions at the cellular and organ level. Elevations of cholesterol are associated with conditions caused by an inherited defect in lipoprotein metabolism, liver disease, kidney disease, or a disorder of the endocrine system.

- Acute intermittent porphyria
- Alcoholism
- Anorexia nervosa
- Cholestasis
- Chronic renal failure
- Diabetes (with poor control)
- Diets high in cholesterol and fats
- Familial hyperlipoproteinemia
- Glomerulonephritis
- Glycogen storage disease (von Gierke's disease)
- Gout
- Hypothyroidism (primary)
- Ischemic heart disease
- Nephrotic syndrome
- Obesity
- Pancreatic and prostatic malignancy
- Pregnancy
- Syndrome X (metabolic syndrome)
- Werner's syndrome

Decreased in

Although the exact pathophysiology is unknown, cholesterol is required for many functions at the cellular and organ level. Decreases in cholesterol levels are associated with conditions caused by malnutrition,

malabsorption, liver disease, and sudden increased utilization.

- Burns
- Chronic myelocytic leukemia
- Chronic obstructive pulmonary disease
- Hyperthyroidism
- Liver disease (severe)
- Malabsorption and malnutrition syndromes
- Myeloma
- Pernicious anemia
- Polycythemia vera
- Severe illness
- Sideroblastic anemias
- Tangier disease
- Thalassemia
- Waldenström's macroglobulinemia

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase cholesterol levels include amiodarone, androgens, β -blockers, calcitriol, cortisone, cyclosporine, danazol, diclofenac, disulfiram, fluoxymesterone, glucogenic corticosteroids, ibuprofen, isotretinoin, levodopa, mepazine, methyclothiazide, miconazole (owing to castor oil vehicle, not the drug), nafarelin, nandrolone, some oral contraceptives, oxymetholone, phenobarbital, phenothiazine, prochlorperazine, sotalol, thiabendazole, thioracil, tretinoin, and trifluoperazine.
- Drugs that may decrease cholesterol levels include acebutolol, amiloride, aminosalicic acid, androsterone, ascorbic acid, asparaginase, atenolol, atorvastatin, beclobrate, bezafibrate, carbutamide, cerivastatin, cholestyramine, ciprofibrate, clofibrate, clonidine, colestipol, dextrothyroxine, doxazosin, enalapril, estrogens, fenfluramine, fenofibrate, fluvastatin, gemfibrozil, haloperidol, hormone replacement therapy, hydralazine, hydrochlorothiazide, interferon,

- isoniazid, kanamycin, ketoconazole, lincomycin, lisinopril, lovastatin, metformin, nafenopin, nandrolone, neomycin, niacin, nicotinic acid, nifedipine, oxandrolone, paromomycin, pravastatin, probucol, simvastatin, tamoxifen, terazosin, thyroxine, trazodone, triiodothyronine, ursodiol, valproic acid, and verapamil.
- Ingestion of alcohol 12 to 24 hr before the test can falsely elevate results.
- Ingestion of drugs that alter cholesterol levels within 12 hr of the test may give a false impression of cholesterol levels, unless the test is done to evaluate such effects.
- Positioning can affect results; lower levels are obtained if the specimen is from a patient who has been supine for 20 min.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to myocardial ischemia; myocardial infarction; pericarditis; coronary vasospasm; ventricular hypertrophy; embolism; epicardial artery inflammation</i>)	Reports of chest pain, new onset of angina, shortness of breath, pallor, weakness, diaphoresis, palpitations, nausea, vomiting, epigastric pain or discomfort, increased blood pressure, increased heart rate	Assess pain characteristics, squeezing pressure, location in substernal back, neck, or jaw; assess pain duration and onset (minimal exertion, sleep, or rest); identify pain modalities that have relieved pain in the past; monitor cardiac biomarkers (CK-MB, troponin, myoglobin); collaborate with ancillary departments to complete ordered echocardiography, exercise stress testing, pharmacological stress testing; administer prescribed pain medication; monitor and trend vital signs; administer prescribed oxygen; administer prescribed anticoagulants, antiplatelets, beta blockers, calcium channel blockers, angiotensin-converting enzyme (ACE) inhibitors, Angiotensin II Receptor Blockers (ARBs), thrombolytic agents

(table continues on page 432)

Problem	Signs & Symptoms	Interventions
Cardiac output <i>(Related to increased preload; increased afterload; impaired cardiac contractility; cardiac muscle disease; altered cardiac conduction)</i>	Decreased peripheral pulses; decreased urinary output; cool, clammy skin; tachypnea; dyspnea; edema; altered level of consciousness; abnormal heart sounds; crackles in lungs; decreased activity tolerance; weight gain; fatigue; hypoxia	Assess peripheral pulses and capillary refill; monitor blood pressure and check for orthostatic changes; assess respiratory rate, breath sounds, and orthopnea; assess skin color and temperature; assess level of consciousness; monitor urinary output; use pulse oximetry to monitor oxygenation; monitor sodium and potassium levels; monitor B-type natriuretic peptide (BNP) levels; administer ordered (ACE) inhibitors, beta blockers, diuretics, aldosterone antagonists, and vasodilators; provide oxygen administration
Health management <i>(Related to failure to regulate diet; lack of exercise; alcohol use; smoking)</i>	Inability or failure to recognize or process information toward improving health and preventing illness with associated mental and physical effects	Encourage regular participation in weight-bearing exercise; assess diet, smoking, and alcohol use; teach the importance of adequate calcium intake with diet and supplements; refer to smoking cessation and alcohol treatment programs; collaborate with HCP for bone density evaluation
Nutrition <i>(Related to excess caloric intake with large amounts of dietary sodium and fat; cultural lifestyle; overeating associated with anxiety, depression, compulsive disorder; genetics; inadequate or unhealthy food resources)</i>	Observable obesity; high-fat or sodium food selections; high BMI; high consumption of ethnic foods; sedentary lifestyle; dietary religious beliefs and food selections; binge eating; diet high in refined sugar; repetitive dieting and failure	Discuss ideal body weight and the purpose and relationship between ideal weight and caloric intake to support cardiac health; review ways to decrease intake of saturated fats and increase intake of polyunsaturated fats; discuss limiting cholesterol intake to less than 300 mg per day; discuss limiting the intake of refined processed sugar; teach limiting sodium intake to the HCP's recommended restriction; encourage intake of fresh fruits and vegetables, unprocessed carbohydrates, poultry, and grains

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with evaluation of cholesterol level.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, gastrointestinal, and hepatobiliary systems, as well as results of previously performed laboratory tests and diagnostic and surgical procedures. The presence of other risk factors, such as family history of heart disease, smoking, obesity, diet, lack of physical activity, hypertension, diabetes, previous myocardial infarction, and previous vascular disease, should be investigated.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to withhold alcohol and drugs known to alter cholesterol levels for 12 to 24 hr before specimen collection, at the direction of the health-care provider (HCP).
- ▶ Note that there are no fluid or medication restrictions unless by medical direction.
- ▶ Instruct the patient to fast 6 to 12 hr before specimen collection; fasting is required if triglyceride measurements are included and recommended if cholesterol levels alone are measured for screening. Protocols may vary among facilities.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions and pretesting preparations; ensure that food has

- been restricted for at least 6 to 12 hr prior to the procedure if triglycerides are to be measured.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet as directed by the HCP.
- ▶ Secondary causes for increased cholesterol levels should be ruled out before therapy to decrease levels is initiated by use of drugs.
- ▶ **Nutritional Considerations:** Increases in total cholesterol levels may be associated with CAD. Nutritional therapy is recommended for the patient identified to be at risk for developing coronary artery disease (CAD) or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation of moderate aerobic physical activity three to four times per

week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

♦ **Social and Cultural Considerations:**

Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.

- ♦ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy.
- ♦ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ♦ Discuss the implications of abnormal test results on the patient's lifestyle.
- ♦ Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- ♦ Educate the patient regarding access to counseling services.
- ♦ Provide contact information, if desired, for the AHA (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- ♦ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ♦ Answer any questions or address any concerns voiced by the patient or family.
- ♦ Explain to the patient and the family the anatomy and pathophysiology of the heart and coronary arteries.
- ♦ Explain to the patient and the family the risk factors for coronary artery disease.

Expected Patient Outcomes:

Knowledge

- ♦ Differentiates between the signs and symptoms of myocardial infarction and angina
- ♦ Describes the signs and symptoms of heart attack

Skills

- ♦ Demonstrates readiness to learn and identified their learning preferences
- ♦ Demonstrates making food selections that are low in saturated fats and high in polyunsaturated fats

Attitude

- ♦ Displays an emotional response to the cardiac event that is appropriate to the circumstances
- ♦ Complies with recommended lifestyle alterations and involvement in cardiac rehabilitation

RELATED MONOGRAPHS:

- ♦ Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BNP, calcium, cholesterol (HDL and LDL), CT cardiac scoring, CRP, CK and isoenzymes, echocardiography, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, MRI chest, magnesium, MI scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, triglycerides, and troponin.
- ♦ Refer to the Cardiovascular, Gastrointestinal, and Hepatobiliary systems tables at the end of the book for related tests by body system.

Chromosome Analysis, Blood

SYNONYM/ACRONYM: N/A.

COMMON USE: To test for suspected chromosomal disorders that result in birth defects such as Down's syndrome.

SPECIMEN: Whole blood (2 mL) collected in a green-top (sodium heparin) tube.

NORMAL FINDINGS: (Method:Tissue culture and microscopic analysis) No chromosomal abnormalities identified.

DESCRIPTION: Cytogenetics is a specialization within the area of genetics that includes chromosome analysis or karyotyping. Chromosome analysis or karyotyping involves comparison of test samples against normal chromosome patterns of number and structure. A normal karyotype consists of 22 pairs of autosomal chromosomes and one pair sex chromosomes, XX for female and XY for male. Variations in number or structure can be congenital or acquired. Variations can range from a small, single-gene mutation to abnormalities in an entire chromosome or set of chromosomes due to duplication, deletion, substitution, translocation, or other rearrangement. Molecular probe techniques are used to detect smaller, more subtle changes in chromosomes. Cells are incubated in culture media to increase the number of cells available for study and to allow for hybridization of the cellular DNA with fluorescent DNA probes in a technique called fluorescence in situ hybridization (FISH). The probes are designed to target areas of the chromosome known to

correlate with genetic risk for a particular disease. When a suitable volume of hybridized sample is achieved, cell growth is chemically inhibited during the prophase and metaphase stages of mitosis (cell division), and cellular DNA is examined to detect fluorescence, which represents chromosomal abnormalities, in the targeted areas. Amniotic fluid, chorionic villus sampling, and cells from fetal tissue or products of conception can also be evaluated for chromosomal abnormalities.

This procedure is contraindicated for

- ◆ Circumstances where the parents are not emotionally capable of understanding the test results and managing the ramifications of the test results.

INDICATIONS

- Evaluate conditions related to cryptorchidism, hypogonadism, primary amenorrhea, and infertility
- Evaluate congenital anomaly, delayed development (physical or mental), mental retardation, and ambiguous sexual organs

- Investigate the carrier status of patients or relatives with known genetic abnormalities
- Investigate the cause of still birth or multiple miscarriages
- Investigate types of solid tumor or hematologic malignancies
- Provide prenatal care or genetic counseling

POTENTIAL DIAGNOSIS

The following tables list some common genetic defects.

Syndrome	Autosomal Chromosome Defect	Features
Angleman	Deletion 15q11–q13	Developmental delays (physical growth, communication, and motor skills); hyperactive behavior; overall happy demeanor with frequent laughter and hand-flapping actions; fascination with water
Beckwith-Wiedemann Bloom	Duplication 11p15 Mutations of BLM, 15	Macroglossia, omphalocele, earlobe creases Birth weight and length are below normal and stature remains below normal to adulthood; skin changes in response to sun exposure; increased risk of cancers which develop early in life; high-pitched voice; distinctive facial features (long, narrow face with a small jaw; large nose and ears)
Canavan	Mutations of ASPA, 17p13.3	Developmental delays that become obvious at 3 to 5 months of age; hypotonia that contributes to inability to roll over, sit upright, or swallow; macrocephaly; and intellectual disability
Cat's eye Cri du chat	Trisomy 2q11 Deletion 5p	Anal atresia, coloboma Catlike cry, microcephaly, hypertelorism, intellectual disability, retrognathia
Cystic fibrosis	Mutations of CFTR, 7	Impaired transport of chloride affects the movement of water in and out of the cells lining the lungs and pancreas. The result is production of thick mucus that obstructs airways and prevents normal function of the affected organs; life threatening, permanent lung damage

Syndrome	Autosomal Chromosome Defect	Features
DiGeorge	Deletion 22q11.2	There is a wide variety in the type and severity of problems associated with this syndrome of impaired development of body systems, most commonly included: cardiac abnormalities or defects, poor immune system function (hypothymic or absent thymus), cleft palate, hypoparathyroidism (low calcium); behavioral disorders; distinctive facial features (long face with downturned mouth, asymmetric face when crying, microcephaly, hooded eye lids, malformed ears)
Down	Trisomy 21	Epicanthal folds, simian crease of palm, flat nasal bridge, mental retardation, congenital heart disease
Edwards	Trisomy 18	Micrognathia, clenched third/fourth fingers with the fifth finger overlapping, rocker-bottom feet, mental retardation, congenital heart disease
Gaucher's	Mutations of GBA, 1	Hepatomegaly and splenomegaly related to accumulation of lipids; anemia; thrombocytopenia; bone disease (bone pain, fractures, and arthritis).
Maple Syrup	Mutations of BCKDHA, BCKDHB, DBT, and DLD, 19	Developmental delays; poor feeding; lethargy; distinctive maple syrup odor in urine
Miller-Dieker	Deletion 17	Lissencephaly (incomplete or absent development of the folds of the cerebrum); microcephaly; developmental delays, especially in growth; intellectual disability with seizures; difficulty feeding and failure to thrive; cardiac malformations
Niemann-Pick	Chromosome 14q24.3 (type C2), 18q11.2 (type C1), 11p15.4–p15.1 (types A & B)	Both types demonstrate symptoms that reflect abnormalities in liver and lung function; blood tests show hyperlipidemia (cholesterol and other fats) and thrombocytopenia

(table continues on page 438)

Syndrome	Autosomal Chromosome Defect	Features
Pallister-Killian	Trisomy 12p	Psychomotor delay, sparse anterior scalp hair, micrognathia, hypotonia
Patau	Trisomy 13	Microcephaly, cleft palate or lip, polydactyly, mental retardation, congenital heart disease
Prader-Willi	Deletion 15q11–q13	Delayed development; distinctive facial features (narrow forehead, almond-shaped eyes, triangular-shaped mouth, diminished stature with small hands and feet); hypotonia; childhood development of an insatiable appetite, hyperphagia, and obesity; mild to moderate intellectual disability; behavioral problems (outbursts of anger and compulsive behavior such as picking at the skin)
Smith-Magenis	Deletion 17p11.2	The major features of this condition include mild to moderate intellectual disability, delayed speech and language skills, distinctive facial features, sleep disturbances, and behavioral problems
Tay-Sachs	Mutations of HEXA, 15q24.1	Normal development until age 3 to 6 mo when development slows and hypotonia affects motor skills such as ability to turn over, sit upright, and crawl; exaggerated startle reaction to loud noises; seizures; eventual loss of vision (cherry red spot upon eye exam is characteristic) and hearing; intellectual disability
Warkam	Mosaic trisomy 8	Malformed ears, bulbous nose, deep palm creases, absent or hypoplastic patellae
Wolf-Hirschhorn	Deletion 4p16.3	Microcephaly, growth retardation, mental retardation, carp mouth

Syndrome	Sex-Chromosome Defect	Features
Fragile X	Xq27.3	Intellectual disability; autism and autism spectrum disorders
XYY	47,XYY	Tall, increased risk of behavior problems
Klinefelter	47,XXY	Hypogonadism, infertility, underdeveloped secondary sex characteristics, learning disabilities

Syndrome	Sex-Chromosome Defect	Features
Rett	Mutations of, Xq28	Severe and progressive developmental problems related to brain functions such as speech, motor and intelligence begin after 6 to 18 mo of normal growth; brain disorder almost exclusively affecting females; slower than normal physical growth; microcephaly; meaningful use of hands is lost in early childhood and replaced by repetitive random hand motions such as clapping or wringing.
Triple X	47,XXX	Increased risk of infertility and learning disabilities
Ullrich-Turner	45,X	Short, gonadal dysgenesis, webbed neck, low posterior hairline, renal and cardiovascular abnormalities

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of potential birth defects.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's reproductive system, family history of known or suspected genetic disorders, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen

collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.

Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.

Recognize anxiety related to test results, and be supportive of the sensitive nature of the testing. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Social and Cultural Considerations:

Encourage the family to seek counseling if they are contemplating pregnancy termination or to seek genetic counseling if a chromosomal abnormality is determined. Decisions regarding elective abortion should occur in the presence of both parents.

Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if fetal abnormalities are detected. Educate the patient and family regarding access to counseling services, as appropriate.

Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor changes in health status and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include α_1 -fetoprotein, amniotic fluid analysis, biopsy chorionic villus, newborn screening, and US biophysical profile obstetric.

Refer to the Reproductive System table at the end of the book for related tests by body system.

Clot Retraction

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in the diagnosis of bleeding disorders.

SPECIMEN: Whole blood collected in a full 5-mL red-top tube.

NORMAL FINDINGS: (Method: Macroscopic observation of sample) A normal clot, gently separated from the side of the test tube and incubated at 37°C, shrinks to about half of its original size within 1 hr. The result is a firm, cylindrical fibrin clot that contains red blood cells and is sharply demarcated from the clear serum. Complete clot retraction can take 6 to 24 hr.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Anemia (severe) (*related to inadequate numbers of red blood cells (RBCs) that quickly produce a clot*)
- Hypofibrinogenemia, dysfibrinogenemia, disseminated intravascular coagulation (DIC) (*evidenced by rapid formation of a small, loosely formed clot; absence of functional fibrinogen reduces fibrinolysis*)
- Medications like aspirin (*related to effect of acetylsalicylic acid as a potentiator of platelet aggregation*)

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Decreased in

- Glanzmann's thrombasthenia (*related to autosomal recessive abnormality of platelet glycoprotein IIb-IIIa required for platelet aggregation*)
- Polycythemia (*related to excessive numbers of RBCs that physically limit the extent to which the clot can retract*)
- Thrombocytopenia (*related to inadequate numbers of platelets to produce a well-formed clot*)
- von Willebrand disease (*related to deficiency of von Willebrand factor required for platelet aggregation*)
- Waldenström's macroglobulinemia (*related to excessive production of paraproteins that physically obstruct platelet aggregation*)

CRITICAL FINDINGS: N/A

Coagulation Factors

SYNONYM/ACRONYM: See table.

COMMON USE: To detect factor deficiencies and related coagulopathies such as found in disseminated intravascular coagulation (DIC).

SPECIMEN: Whole blood collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Photo-optical clot detection) Activity from 50% to 150%.

	Coagulation Test Responses in the Presence of Factor Deficiency	Role in Modern Coagulation Cascade Model	Synonym	Preferred Name	Synonym
Factor I	PT prolonged, aPTT prolonged	Assists in the formation of the fibrin clot	–	Fibrinogen	–
Factor II	PT prolonged, aPTT prolonged	Assists factor Xa in formation of trace thrombin in the initiation phase and assists factors VIIIa, IXa, Xa, and Va to form thrombin in the propagation phase of hemostasis	Prothrombin	Prothrombin	Prothrombin
Tissue factor (formerly known as factor III)	PT prolonged, aPTT prolonged	Assists factor VII and Ca ²⁺ in the activation of factors IX and X during the initiation phase of hemostasis	Tissue thromboplastin	Tissue factor	Tissue thromboplastin
Calcium (formerly known as factor IV)	N/A	Essential to the activation of multiple clotting factors	Ca ²⁺	Calcium	Ca ²⁺
Factor V	PT prolonged, aPTT prolonged	Assists factors VIIIa, IXa, Xa, and II in the formation of thrombin during the amplification and propagation phases of hemostasis	Labile factor, accelerator globulin (AcG)	Proaccelerin	Labile factor, accelerator globulin (AcG)
Factor VII	PT prolonged, aPTT normal	Assists tissue factor and Ca ²⁺ in the activation of factors IX and X	Stable factor, serum prothrombin conversion accelerator, autoprothrombin I	Proconvertin	Stable factor, serum prothrombin conversion accelerator, autoprothrombin I
Factor VIII	PT normal, aPTT prolonged	Activated by trace thrombin during the initiation phase of hemostasis to amplify formation of additional thrombin	Antihemophilic factor A, platelet cofactor 1	Antihemophilic factor (AHF)	Antihemophilic globulin (AHG), antihemophilic factor A, platelet cofactor 1

	Coagulation Test Responses in the Presence of Factor Deficiency	Role in Modern Coagulation Cascade Model	Synonym	Preferred Name
Factor IX	PT normal, aPTT prolonged	Assists factors Va and VIIIa in the amplification phase and factors VIIIa, Xa, Va, and II to form thrombin in the propagation phase	Christmas factor, antihemophilic factor B, platelet cofactor 2	Plasma thromboplastin component (PTC)
Factor X	PT prolonged, aPTT prolonged	Assists with formation of trace thrombin in the initiation phase and acts with factors VIIIa, IXa, Va, and II to form thrombin in the propagation phase	Autoprothrombin III, thrombokinase	Stuart-Prower factor
Factor XI	PT normal, aPTT prolonged	Activated by thrombin produced in the extrinsic pathway to enhance production of additional thrombin inside the fibrin clot via the intrinsic pathway; this factor also participates in slowing down the process of fibrinolysis	Antihemophilic factor C	Plasma thromboplastin antecedent (PTA)
Factor XII	PT normal, aPTT prolonged	Contact activator of the kinin system (e.g., prekallikrein, and high-molecular-weight kininogen)	Glass factor, contact factor	Hageman factor
Factor XIII	PT normal, aPTT normal	Activated by thrombin and assists in formation of bonds between fibrin strands to complete secondary hemostasis	Laki-Lorand factor (LLF), fibrinase, plasma transglutaminase	Fibrin-stabilizing factor (FSF)
von Willebrand factor	Ristocetin cofactor decreased	Assists in platelet adhesion and thrombus formation	vWF	von Willebrand factor

DESCRIPTION: Hemostasis involves three components: blood vessel walls, platelets, and plasma coagulation proteins. Primary hemostasis has three major stages involving platelet adhesion, platelet activation, and platelet aggregation. Platelet adhesion is initiated by exposure of the endothelium as a result of damage to blood vessels. Exposed tissue factor-bearing cells trigger the simultaneous binding of von Willebrand factor to exposed collagen and circulating platelets. Activated platelets release a number of procoagulant factors, including thromboxane, a very potent platelet activator, from storage granules. These factors enter the circulation and activate other platelets, and the cycle continues. The activated platelets aggregate at the site of vessel injury, and at this stage of hemostasis, the glycoprotein IIb/IIIa receptors on the activated platelets bind fibrinogen, causing the platelets to stick together and form a plug. There is a balance in health between the prothrombotic or clot formation process and the antithrombotic or clot disintegration process. Simultaneously, the coagulation process or secondary hemostasis occurs. In secondary hemostasis, the coagulation proteins respond to blood vessel injury in an overlapping chain of events. The contact activation (formerly known as the intrinsic pathway) and tissue factor (formerly known as the extrinsic pathway) pathways of secondary hemostasis are a series of reactions involving the substrate protein fibrinogen, the coagulation factors (also known as *enzyme precursors* or *zymogens*), nonenzymatic cofactors (Ca^{2+}), and phospholipids. The factors were assigned Roman

numerals in the order of their discovery, not their place in the coagulation sequence. Factor VI was originally thought to be a separate clotting factor. It was subsequently proved to be the same as a modified form of factor Va, and therefore, the number is no longer used.

The antithrombotic process includes tissue factor pathway inhibitor (TFPI), antithrombin, protein C, and fibrinolysis.

The coagulation factors are formed in the liver. They can be divided into three groups based on their common properties:

1. The contact group is activated in vitro by a surface such as glass and is activated in vivo by collagen. The contact group includes factor XI, factor XII, prekallikrein, and high-molecular-weight kininogen.
2. The prothrombin or vitamin K-dependent group includes factors II, VII, IX, and X.
3. The fibrinogen group includes factors I, V, VIII, and XIII. They are the most labile of the factors and are consumed during the coagulation process. The factors listed in the table are the ones most commonly measured.

For many years it was believed that the intrinsic and extrinsic pathways operated equally, in parallel. A more modern concept of the coagulation process has replaced the traditional model (formerly called the coagulation cascade) and is presented on the next page. The cellular-based model includes four overlapping phases in the formation of thrombin: initiation, amplification, propagation, and termination. It is now known that the tissue factor pathway is the primary pathway for the initiation of blood coagulation. Tissue factor

(TF)-bearing cells (e.g., endothelial cells, smooth muscle cells, monocytes) can be induced to express TF and are the primary initiators of the coagulation cascade either by contact activation or trauma. The contact activation pathway is more related to inflammation, and although it plays an important role in the body's reaction to damaged endothelial surfaces, a deficiency in factor XII does not result in development of a bleeding disorder, which demonstrates the minor role of the intrinsic pathway in the process of blood coagulation.

Substances such as endotoxins, tumor necrosis factor alpha, and lipoproteins can also stimulate expression of TF. TF, in combination with factor VII and calcium, forms a complex that then activates factors IX and X in the initiation phase. Activated factor X in the presence of factor II (prothrombin) leads to the formation of thrombin. TFPI quickly inactivates this stage of the pathway so that limited or trace amounts of thrombin are produced, which results in the activation of factors VIII and V. Activated factor IX, assisted by activated factors V and VIII, initiate amplification and propagation of thrombin in the cascade. Thrombin activates factor XIII and begins converting fibrinogen into fibrin monomers, which spontaneously polymerize and then become cross-linked into a stable clot by activated factor XIII.

Qualitative and quantitative factor deficiencies can affect the function of the coagulation pathways. Factor V and factor II (prothrombin) mutations are examples of qualitative deficiencies and are the most common inherited predisposing factors for blood clots. Approximately 5% to 7% of Caucasians, 2% of Hispanics, 1% of

African Americans and Native American, and 0.5% of Asians have the factor V Leiden mutation, and 2% to 3% of Caucasians and 0.3% of African Americans have a prothrombin mutation. Hemophilia A is an inherited deficiency of factor VIII and occurs at a prevalence of about 1 in 5,000 to 10,000 male births. Hemophilia B is an inherited deficiency of factor IX and occurs at a prevalence of about 1 in about 20,000 to 34,000 male births. Genetic testing is available for inherited mutations associated with inherited coagulopathies. The tests are performed on samples of whole blood. Counseling and informed written consent are generally required for genetic testing.

The PT/INR measures the function of the tissue factor pathway of coagulation and is used to monitor patients receiving warfarin or coumarin-derivative anticoagulant therapy. The aPTT measures the function of the contact activation pathway of coagulation and is used to monitor patients receiving heparin anticoagulant therapy.

This procedure is contraindicated for: N/A

INDICATIONS

- Identify the presence of inherited bleeding disorders
- Identify the presence of qualitative or quantitative factor deficiency

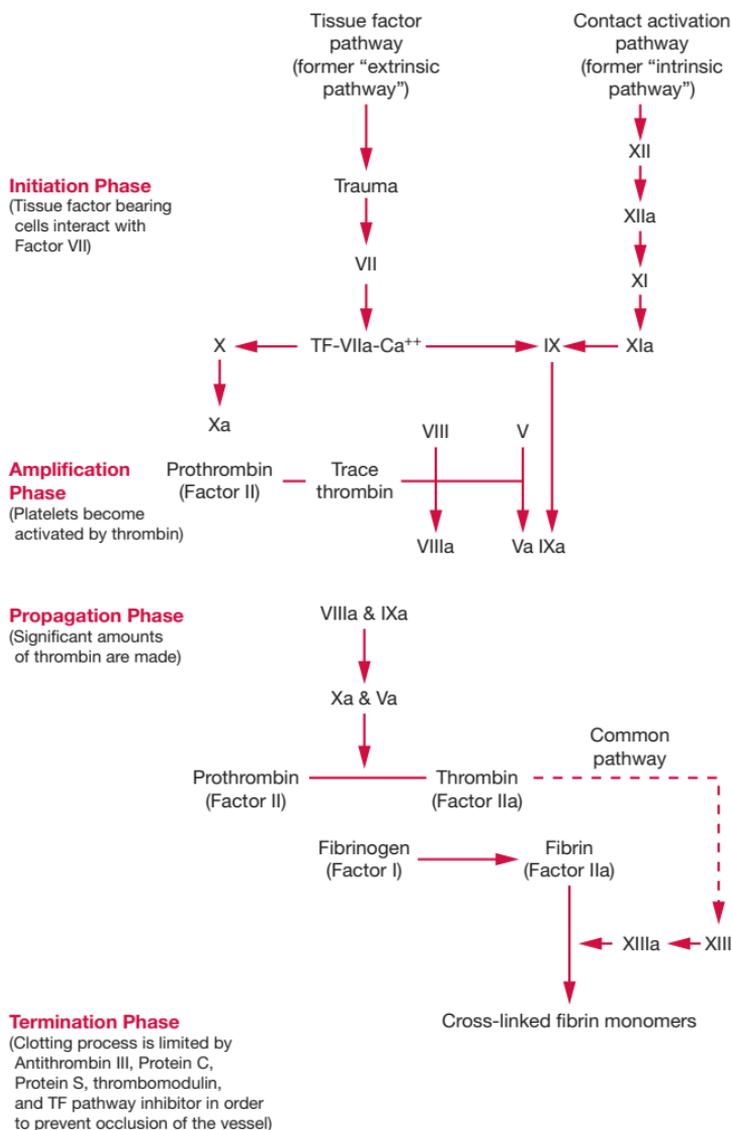

POTENTIAL DIAGNOSIS

Increased in: N/A

Decreased in

- Congenital deficiency
- Disseminated intravascular coagulation (*related to consumption of factors as part of the coagulation cascade*)

Coagulation Process

- Liver disease (*related to inability of damaged liver to synthesize coagulation factors*)

CRITICAL FINDINGS 

Fibrinogen: Less than 80 mg/dL (SI: Less than 2.4 micromol/L).

Note and immediately report to the health-care provider (HCP) any critically decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical

value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Signs and symptoms of microvascular thrombosis include cyanosis, ischemic tissue necrosis, hemorrhagic necrosis, tachypnea, dyspnea, pulmonary emboli, venous distention, abdominal pain, and oliguria. Possible interventions include identification and treatment of the underlying cause, support through administration of required blood products (cryoprecipitate or fresh frozen plasma), and administration of heparin. Cryoprecipitate may be a more effective product than fresh frozen plasma in cases where the fibrinogen level is less than 100 mg/dL, the minimum level required for adequate hemostasis, because it delivers a concentrated amount of fibrinogen without as much plasma volume.

INTERFERING FACTORS

- Drugs that may increase factor II levels include fluoxymesterone, methandrostenolone, nandrolone, and oxymetholone.
- Drugs that may decrease factor II levels include warfarin.
- Drugs that may increase factor V, VII, and X levels include anabolic steroids, fluoxymesterone, methandrostenolone, nandrolone, oral contraceptives, and oxymetholone.
- Drugs that may decrease factor V levels include streptokinase.
- Drugs that may decrease factor VII levels include acetylsalicylic acid, asparaginase, cefamandole, ceftriaxone, dextran, dicumarol, gemfibrozil, oral contraceptives, and warfarin.
- Drugs that may increase factor VIII levels include chlormadinone.
- Drugs that may decrease factor VIII levels include asparaginase.
- Drugs that may increase factor IX levels include chlormadinone and oral contraceptives.
- Drugs that may decrease factor IX levels include asparaginase and warfarin.
- Drugs that may decrease factor X levels include chlormadinone, dicumarol, oral contraceptives, and warfarin.
- Drugs that may decrease factor XI levels include asparaginase and captopril.
- Drugs that may decrease factor XII levels include captopril.
- Test results of patients on anticoagulant therapy are unreliable.
- Placement of tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.
- Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.
- Incompletely filled collection tubes, specimens contaminated with heparin, clotted specimens, or unprocessed specimens not delivered to the laboratory within 1 to 2 hr of collection should be rejected.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Bleeding (<i>Related to altered clotting factors secondary to heparin use or depleted clotting factors</i>)	Altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; capillary refill greater than 3 sec; cool extremities	Increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; administer stool softeners as needed; monitor stool for blood; encourage intake of foods rich in vitamin K; monitor and trend HGB/HCT; assess skin for petechiae, purpura, hematoma; monitor for blood in emesis, or sputum; institute bleeding precautions (prevent unnecessary venipuncture; avoid IM injections; prevent trauma; be gentle with oral care, suctioning; avoid use of a sharp razor); administer prescribed medications (recombinant human activated protein C; epsilon aminocaproic acid)
Gas exchange (<i>Related to deficient oxygen capacity of the blood</i>)	Irregular breathing pattern, use of accessory muscles; altered chest excursion; adventitious breath sounds (crackles, rhonchi, wheezes, diminished breath sounds); copious secretions; signs of hypoxia; altered blood gas results; confusion; lethargy; cyanosis	Monitor respiratory rate and effort based on assessment of patient condition; assess lung sounds frequently; monitor for secretions, bloody sputum; suction as necessary; use pulse oximetry to monitor oxygen saturation; collaborate with physician to administer oxygen as needed; elevate the head of the bed 30 degrees or higher; monitor IV fluids and avoid aggressive fluid resuscitation; assess level of consciousness; anticipate the need for possible intubation

Problem	Signs & Symptoms	Interventions
Tissue perfusion (<i>Related to compromised clotting factor; blood loss; deficient oxygen-carrying capacity of the blood</i>)	Hypotension; dizziness; cool extremities; capillary refill greater than 3 sec; weak pedal pulses; altered level of consciousness	Monitor blood pressure; assess for dizziness; check skin temperature for warmth; assess capillary refill; assess pedal pulses; monitor level of consciousness; administer prescribed vasodilators and inotropic drugs; use oxygen as required
Confusion (<i>Related to an alteration in the oxygen-carrying capacity of the blood; blood loss; compromised clotting factor</i>)	Disorganized thinking, restless, irritable, altered concentration and attention span, changeable mental function over the day, hallucinations; altered attention span; inability to follow directions; disorientation to person, place, time, and purpose; inappropriate affect	Treat the medical condition; correlate confusion with the need to reverse altered electrolytes; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or restraints; consider pharmacological interventions; record accurate intake and output to assess fluid status; administer blood or blood products; monitor and trend HGB/HCT

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating the effectiveness of blood clotting and identify deficiencies in blood factor levels.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic and hepatobiliary systems, any bleeding disorders, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications. Include anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be

discontinued by medical direction for the appropriate number of days prior to a surgical procedure.

- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) tubes. Otherwise, when using a standard vacutainer system, the blue top is the first tube collected. When a butterfly is used and due to the added tubing, an extra red-top tube should be collected before the blue-top tube to ensure complete filling of the blue top tube.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. The Clinical Laboratory Standards Institute (CLSI) recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education

- ▶ Instruct the patient to report immediately any signs of unusual bleeding or bruising.
- ▶ Inform the patient with decreased factor levels of the importance of taking precautions against bruising and bleeding.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes

Knowledge

- ▶ States bleeding precautions that include the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections
- ▶ States importance of monitoring stool, sputum, and urine for blood

Skills

- ▶ Demonstrates proficiency in self-administering prescribed medications
- ▶ Demonstrates proficiency in adequately elevating the head of the bed to facilitate adequate gas exchange

Attitude

- ▶ Complies with the recommendation to refrain from risky behavior that could result in trauma and bleeding
- ▶ Adheres to the recommendation to report any new bleeding to the HCP

RELATED MONOGRAPHS:

- ▶ Related tests include aPTT, ALT, ALP, AT-III, AST, clot retraction, CBC platelet count, copper, fibrinogen, FDP, plasminogen, procalcitonin, protein C, protein S, PT/INR, and vitamin K.
- ▶ Refer to the Hematopoietic and Hepatobiliary systems tables at the end of the book for related tests by body system.

Cold Agglutinin Titer

SYNONYM/ACRONYM: Mycoplasma serology.

COMMON USE: To identify and confirm the presence of viral infections such as found in atypical pneumonia.

SPECIMEN: Serum (2 mL) collected in a red-top tube. The tube must be placed in a water bath or heat block at 37°C for 1 hr and allowed to clot before the serum is separated from the red blood cells (RBCs).

NORMAL FINDINGS: (Method: Patient serum containing autoantibodies titered against type O RBCs at 2°C to 8°C. Type O cells are used because they have no antigens on the cell membrane surface. Agglutination with patient sera would not occur because of reaction between RBC blood type antigens and patient blood type antibodies.) Negative: Single titer less than 1:32 or less than a four-fold increase in titer over serial samples. High titers may appear spontaneously in elderly patients and persist for many years.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Mycoplasma infection stimulates production of antibodies against specific RBC antigens in affected individuals

- Cirrhosis
- Gangrene
- Hemolytic anemia
- Infectious diseases (e.g., staphylococemia, influenza, tuberculosis)

- Infectious mononucleosis
- Malaria
- M. pneumoniae (primary atypical pneumonia)
- Multiple myeloma
- Pulmonary embolism
- Raynaud's disease (severe)
- Systemic lupus erythematosus
- Trypanosomiasis

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Collagen Cross-Linked N-Telopeptide

SYNONYM/ACRONYM: NT_x.

COMMON USE: To evaluate the effectiveness of treatment for osteoporosis.

SPECIMEN: Urine (2 mL) from a random specimen collected in a clean plastic container.

NORMAL FINDINGS: (Method: Immunoassay)

Adult male 18–29 yr	Less than 100 mmol bone collagen equivalents (BCE)/mmol creatinine
Adult male 30–59 yr	Less than 65 mmol BCE/mmol creatinine
Adult female (premenopausal)	Less than 65 mmol BCE/mmol creatinine

Tanner Stage	Male	Female
I	55–508 (mmol BCE/mmol creatinine)	6–662 (mmol BCE/mmol creatinine)
II	21–423 (mmol BCE/mmol creatinine)	193–514 (mmol BCE/mmol creatinine)
III	27–462 (mmol BCE/mmol creatinine)	13–632 (mmol BCE/mmol creatinine)
IV	Less than 609 (mmol BCE/mmol creatinine)	Less than 389 (mmol BCE/mmol creatinine)
V	Less than 240 (mmol BCE/mmol creatinine)	Less than 132 (mmol BCE/mmol creatinine)

Values are higher in children.

DESCRIPTION: Osteoporosis is the most common bone disease in the West. It is often called the “silent disease” because bone loss occurs without symptoms. The formation and maintenance of bone mass is dependent on a combination of factors that include genetics, nutrition, exercise, and hormone function. Normally, the rate of bone formation is equal to the rate of bone resorption. After midlife, the rate of bone loss begins to increase. Osteoporosis is more commonly identified in women than in men. Other risk factors include thin, small-framed body structure; family history of osteoporosis; diet low in calcium; white or Asian race; excessive use of alcohol; cigarette smoking; sedentary lifestyle; long-term use of corticosteroids,

thyroid replacement medications, or antiepileptics; history of bulimia, anorexia nervosa, chronic liver disease, or malabsorption disorders; and postmenopausal state. Osteoporosis is a major consequence of menopause in women owing to the decline of estrogen production. Osteoporosis is rare in premenopausal women. Estrogen replacement therapy (after menopause) is one strategy that has been commonly employed to prevent osteoporosis, although its exact protective mechanism is unknown. Results of some recently published studies indicate that there may be significant adverse side effects to estrogen replacement therapy; more research is needed to understand the long-term effects (positive and negative) of this therapy.

Other treatments include raloxifene (selectively modulates estrogen receptors), calcitonin (interacts directly with osteoclasts), and bisphosphates (inhibit osteoclast-mediated bone resorption).

A noninvasive test to detect the presence of collagen cross-linked N-telopeptide (NT_x) is used to follow the progress of patients who have begun treatment for osteoporosis. NT_x is formed when collagenase acts on bone. Small NT_x fragments are excreted in the urine after bone resorption. A desirable response, 2 to 3 mo after therapy is initiated, is a 30% reduction in NT_x and a reduction of 50% below baseline by 12 mo.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the evaluation of osteoporosis
- Assist in the management and treatment of osteoporosis
- Monitor effects of estrogen replacement therapy

POTENTIAL DIAGNOSIS

Increased in

Conditions that reflect increased bone resorption are associated with increased levels of N-telopeptide in the urine

- Alcoholism (*related to inadequate nutrition*)
- Chronic immobilization
- Chronic treatment with anticonvulsants, corticosteroids, gonadotropin

- releasing hormone agonists, heparin, or thyroid hormone
- Conditions that include hypercortisolism, hyperparathyroidism, hyperthyroidism, and hypogonadism
- Gastrointestinal disease (*related to inadequate dietary intake or absorption of minerals required for bone formation and maintenance*)
- Growth disorders (acromegaly, growth hormone deficiency, osteogenesis imperfecta)
- Hyperparathyroidism (*related to imbalance in calcium and phosphorus that affects the rate of bone resorption*)
- Multiple myeloma and metastatic tumors
- Osteomalacia (*related to defective bone mineralization*)
- Osteoporosis
- Paget's disease
- Postmenopausal women (*related to estrogen deficiency*)
- Recent fracture
- Renal insufficiency (*related to excessive loss through renal dysfunction*)
- Rheumatoid arthritis and other connective tissue diseases (*related to inadequate diet due to loss of appetite*)

Decreased in

- Effective therapy for osteoporosis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- NT_x levels are affected by urinary excretion, and values may be influenced by the presence of renal impairment or disease.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Health maintenance <i>(Related to failure to regulate diet; lack of exercise; alcohol use; smoking)</i>	Inability or failure to recognize or process information toward improving health and preventing illness with associated mental and physical effects	Encourage regular participation in weight-bearing exercise; assess diet, smoking, and alcohol use; teach the importance of adequate calcium intake with diet and supplements; refer to smoking cessation and alcohol treatment programs; collaborate with physician for bone density evaluation
Socialization <i>(Related to altered body image and associated change in physical appearance)</i>	Expresses concern about changes in appearance related to kyphosis or lordosis; isolates self at home and refuses to participate in usual social or familial activities; expresses discomfort with social situations; fear of falling	Encourage continuation of activities inclusive of those with whom there is an established friend or family relationship; encourage participation in a community support group; encourage realistic view of physical appearance; acknowledge patient's perception of changed image and the impact on his or her life
Self-care <i>(Related to loss of bone mass and physical deformity; pain; and limited range of motion)</i>	Difficulty fastening clothing; difficulty performing personal hygiene; inability to maintain appropriate appearance; difficulty with independent mobility	Reinforce self-care techniques as taught by occupational therapy; ensure the patient has adequate time to perform self-care; encourage use of assistive devices to maintain independence; ask if there is any interference with lifestyle activities
Fall risk <i>(Related to altered mobility associated with loss of bone mass)</i>	Postural instability; jerky movement; uncoordinated movement; slow, unsteady movement	Teach about fall precautions; assess home environment for fall risk; evaluate medications for contributory cause related to recent falls; encourage physical therapy to facilitate moderate exercise; teach that low, comfortable walking shoes can promote safe ambulation and decrease fall risk

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing osteoporosis and evaluating the effectiveness of therapy.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens.
- ▶ Obtain a history of the patient's musculoskeletal system and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there should be no discomfort during the procedure.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Instruct the patient to collect a second-void morning specimen as follows: (1) void and then drink a glass of water; (2) wait 30 min, and then try to void again.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased NT_x levels may be associated with osteoporosis. Nutritional therapy may be indicated for patients identified as being at high risk for developing osteoporosis. Educate the patient about the National Osteoporosis Foundation's guidelines regarding a regular regimen of weight-bearing exercises, limited alcohol intake, avoidance of tobacco products, and adequate dietary intake of vitamin D and calcium. Dietary calcium can be obtained in animal or plant sources. Milk and milk products, sardines, clams, oysters, salmon, rhubarb, spinach, beet greens, broccoli, kale, tofu, legumes, and fortified orange juice are high in calcium. Milk and milk products also contain vitamin D and lactose to assist in absorption. Cooked vegetables yield more absorbable calcium than raw vegetables. Patients should also be informed of the substances that can inhibit calcium absorption by irreversibly binding to some of the calcium and making it unavailable for absorption, such as oxalates, which naturally occur in some vegetables (e.g., beet greens, collards, leeks, okra, parsley, quinoa, spinach, Swiss chard) and are found in tea; phytic acid, found in some cereals (e.g., wheat bran, wheat germ); phosphoric acid, found in dark cola; and excessive intake of insoluble dietary fiber (in excessive amounts). Excessive protein intake also can affect calcium absorption negatively, especially if it is combined with foods high in phosphorus. Vitamin D is synthesized by the skin and is available in fortified dairy foods and cod liver oil.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to lack of muscular control, perceived loss of independence, and fear of shortened life expectancy.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process

and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org), the Institute of Medicine of the National Academies (www.iom.edu), or the National Osteoporosis Foundation (www.nof.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Discuss with the patient the effect of alcohol consumption on nutritional status and calcium intake.

Expected Patient Outcomes:

Knowledge

- ▶ Identifies the importance of adhering to the recommended therapeutic regime to maintain health
- ▶ Describes the importance of early intervention on preserving bone density and reducing future risk of falls and fractures

Skills

- ▶ Proficiently demonstrates the proper use of assistive devices to support mobility and increase activity
- ▶ Independently demonstrates weight-bearing exercises designed to promote bone growth

Attitude

- ▶ Discusses perceived change in physical appearance with a positive attitude
- ▶ Selects positive changes in lifestyle that can preserve bone health

RELATED MONOGRAPHS:

- ▶ Related tests include ALP, BMD, calcitonin, calcium, creatinine, creatinine clearance, osteocalcin, PTH, phosphorus, radiography bone, and vitamin D.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Colonoscopy

SYNONYM/ACRONYM: Full colonoscopy, lower endoscopy, lower panendoscopy.

COMMON USE: To visualize and assess the lower colon for tumor, cancer, and infection.

AREA OF APPLICATION: Colon.

CONTRAST: Air.

DESCRIPTION: Colonoscopy, a radiological examination of the colon follows instillation of barium (single contrast study) using a rectal tube inserted into the rectum. The patient retains the contrast while a

series of images are obtained, recorded, and available for viewing. Visualization can be improved by draining the barium and using air contrast (double contrast study); some of the barium remains on the

surface of the colon wall, allowing for greater detail in the images. A combination of x-ray and fluoroscopic techniques are used to allow inspection of the mucosa of the entire colon, ileocecal valve, and terminal ileum using a flexible fiberoptic colonoscope inserted through the anus and advanced to the terminal ileum. The colonoscope, a multichannel instrument, allows viewing of the gastrointestinal (GI) tract lining, insufflation of air, aspiration of fluid, collection of tissue biopsy samples, and passage of a laser beam for obliteration of tissue and control of bleeding. Mucosal surfaces of the lower GI tract are examined for ulcerations, polyps, chronic diarrhea, hemorrhagic sites, neoplasms, and strictures. During the procedure, tissue samples may be obtained for cytology, and some therapeutic procedures may be performed, such as excision of small tumors or polyps, coagulation of bleeding sites, and removal of foreign bodies. CT colonoscopy may be indicated for patients who have diseases rendering them unable to undergo conventional colonoscopy (e.g., bleeding disorders, lung or heart disease) and for patients who are unable to undergo the sedation required for traditional colonoscopy.

This procedure is contraindicated for

-  Patients with bleeding disorders or cardiac conditions.
-  Patients with bowel perforation, acute peritonitis, acute colitis, ischemic bowel necrosis, toxic colitis, recent bowel surgery, advanced pregnancy, severe cardiac or pulmonary disease, recent myocardial infarction, known or suspected pulmonary embolus, and large abdominal aortic or iliac aneurysm.

-  Patients who have had a colon anastomosis within the past 14 to 21 days, ***because an anastomosis may break down with gas insufflation.***

INDICATIONS

- Assess GI function in a patient with a personal or family history of colon cancer, polyps, or ulcerative colitis
- Confirm diagnosis of colon cancer and inflammatory bowel disease
- Detect Hirschsprung's disease and determine the areas affected by the disease
- Determine cause of lower GI disorders, especially when barium enema and proctosigmoidoscopy are inconclusive
- Determine source of rectal bleeding and perform hemostasis by coagulation
- Evaluate postsurgical status of colon resection
- Evaluate stools that show a positive occult blood test, lower GI bleeding, or change in bowel habits
- Follow up on previously diagnosed and treated colon cancer
- Investigate iron-deficiency anemia of unknown origin
- Reduce volvulus and intussusception in children
- Remove colon polyps
- Remove foreign bodies and sclerosing strictures by laser

POTENTIAL DIAGNOSIS

Normal findings in

- Normal intestinal mucosa with no abnormalities of structure, function, or mucosal surface in the colon or terminal ileum

Abnormal findings in

- Benign lesions
- Bleeding sites
- Bowel distention
- Bowel infection or inflammation
- Colitis

- Colon cancer
- Crohn's disease
- Diverticula
- Foreign bodies
- Hemorrhoids
- Polyps
- Proctitis
- Tumors
- Vascular abnormalities

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Severe lower GI bleeding or the presence of feces, barium, blood, or blood clots, which can interfere with visualization.
- Spasm of the colon, which can mimic the radiographic signs of cancer. (Note: The use of IV glucagon minimizes spasm.)
- Inability of the patient to tolerate introduction of or retention of barium, air, or both in the bowel.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations

may cause the procedure to be canceled or repeated.

- Bowel preparations that include laxatives or enemas should be avoided in pregnant patients or patients with inflammatory bowel disease unless specifically directed by a health-care provider (HCP).
- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the examination room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the colon for disease.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.

- ▶ Obtain a history of patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Ensure that this procedure is performed before an upper GI study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Note intake of oral iron preparations within 1 wk before the procedure because these cause black, sticky feces that are difficult to remove with bowel preparation.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a GI lab, by an HCP, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Inform the patient that it is important that the bowel be cleaned thoroughly so that the physician can visualize the colon. Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution's policy.
- ▶ Instruct the patient to remove all external metallic objects from the area to be examined.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Instruct the patient to eat a low-residue diet for several days before the procedure and to consume only clear liquids the evening before the test.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ *Make sure a written and Informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Complications of the procedure may include bleeding and cardiac arrhythmias.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Ensure that the patient has complied with dietary, fluid and medication restrictions, and pretesting preparations for at least 8 hr prior to the procedure.
- ▶ Ensure that ordered laxatives were administered late in the afternoon of the day before the procedure.
- ▶ Assess for completion of bowel preparation according to the institution's procedure.

- ▶ Instruct the patient to remove all external metallic objects from the area to be examined.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Obtain and record baseline vital signs.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer medications, as ordered, to reduce discomfort and to promote relaxation and sedation.
- ▶ Place the patient on an examination table in the left lateral decubitus position and drape with the buttocks exposed.
- ▶ The HCP performs a visual inspection of the perianal area and a digital rectal examination.
- ▶ Instruct the patient to bear down as if having a bowel movement as the fiberoptic tube is inserted through the rectum.
- ▶ The scope is advanced through the sigmoid. The patient's position is changed to supine to facilitate passage into the transverse colon. Air is insufflated through the tube during passage to aid in visualization.
- ▶ Instruct the patient to take deep breaths to aid in movement of the scope downward through the ascending colon to the cecum and into the terminal portion of the ileum.
- ▶ Air is insufflated to distend the GI tract, as needed. Biopsies, cultures, or any endoscopic surgery is performed.
- ▶ Foreign bodies or polyps are removed and placed in appropriate specimen containers, labeled, and sent to the laboratory.
- ▶ Photographs are obtained for future reference.
- ▶ At the end of the procedure, excess air and secretions are aspirated through the scope, and the colonoscope is removed.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Monitor the patient for signs of respiratory depression.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, or as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe the patient until the effects of the sedation have worn off.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ Monitor for any rectal bleeding. Instruct the patient to expect slight rectal bleeding for 2 days after removal of polyps or biopsy specimens but that an increasing amount of bleeding or sustained bleeding should be reported to the HCP immediately.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Inform the patient that belching, bloating, or flatulence is the result of air insufflation.
- ▶ Encourage the patient to drink several glasses of water to help replace fluids lost during the preparation for the test.
- ▶ Carefully monitor the patient for fatigue and fluid and electrolyte imbalance.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of occult blood testing, colonoscopy or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society

recommends regular screening for colon cancer, beginning at age 50 yr for individuals without identified risk factors. Their recommendations for frequency of screening: annual for occult blood testing (fecal occult blood testing [FOBT] and fecal immunochemical testing [FIT]); every 5 yr for flexible sigmoidoscopy, double contrast barium enema, and CT colonography; and every 10 yr for colonoscopy. There are both advantages and disadvantages to the screening tests that are available today. Methods to use DNA testing of stool are being investigated and await FDA approval. The DNA test is designed to identify abnormal changes in DNA from the cells in the lining of the colon that are normally shed and excreted in stool. The DNA tests under development use multiple markers to identify colon cancers that demonstrate different, abnormal DNA changes. Unlike some of the current screening methods, the DNA tests would be able to detect precancerous polyps. The most current guidelines for colon cancer screening of the general

population as well as of individuals with increased risk are available from the American Cancer Society (www.cancer.org), U.S. Preventive Services Task Force (www.uspreventiveservicestaskforce.org), and the American College of Gastroenterology (www.gi.org). Answer any questions or address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include barium enema, biopsy intestinal, capsule endoscopy, carcinoembryonic and cancer antigens, CT abdomen, CT colonoscopy, fecal analysis, KUB, MRI abdomen, and proctosigmoidoscopy.
- Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Color Perception Test

SYNONYM/ACRONYM: Color blindness test, Ishihara color perception test, Ishihara pseudoisochromatic plate test.

COMMON USE: To assist in the diagnosis of color blindness.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: Defects in color perception can be hereditary or acquired. The congenital defect for color blindness is carried by the female, who is generally unaffected, and is expressed dominantly in males. Color blindness occurs in 8% of males and 0.4% of

females. It may be partial or complete. The partial form is the hereditary form, and in the majority of patients the color deficiency is in the red-green area of the spectrum. Acquired color blindness may occur as a result of diseases of the retina or optic nerve.

Color perception tests are performed to determine the acuity of color discrimination. The most common test uses pseudoisochromatic plates with numbers or letters buried in a maze of dots. Misreading the numbers or letters indicates a color perception deficiency and may indicate color blindness, a genetic dysfunction, or retinal pathology.

Color perception is important in some occupations and testing for color perception may be a requirement for employment, especially for health-care workers whose responsibilities include assessment and monitoring of symptoms or changes in patients' conditions. Some common examples of color based assessments in a health-care environment include interpreting the results of color pads on blood or urine test strips, identifying changes in body color (e.g. pallor, cyanosis, jaundice), determining the presence of blood or bile in body fluids and feces, or evaluating pH test strips to verify correct placement of a nasopharyngeal tube.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect deficiencies in color perception
- Evaluate because of family history of color visual defects
- Investigate suspected retinal pathology affecting the cones

POTENTIAL DIAGNOSIS

Normal findings in

- Normal visual color discrimination; no difficulty in identification of color combinations

Abnormal findings in

- Identification of some but not all colors

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Inability of the patient to read.
- Poor visual acuity or poor lighting.
- Failure of the patient to wear corrective lenses (glasses or contact lenses).
- Damaged or discolored test plates.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient or parent/child this procedure can assist in detection of color vision impairment.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens.
- ▶ Obtain a history of the patient's known or suspected vision loss; changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- ▶ Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Ask the patient if he or she wears corrective lenses; also inquire about the importance of color discrimination in

his or her work, as applicable. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that a health-care provider (HCP) performs the test in a quiet, darkened room, and that to evaluate both eyes, the test can take 5 to 15 or up to 30 min, depending on the complexity of testing required.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Seat the patient comfortably. Occlude one eye and hold test booklet 12 to 14 in. in front of the exposed eye.
- ▶ Ask the patient to identify the numbers or letters buried in the maze of dots or to trace the objects with a handheld pointed object.
- ▶ Repeat on the other eye.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting HCP, who will discuss the results with the patient.

- ▶ Recognize anxiety related to test results and be supportive of impaired activity related to color vision loss. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information regarding vision aids for people with impaired color perception, if desired: ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research [NIDRR], available at www.abledata.com).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include refraction and slit-lamp biomicroscopy.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Colposcopy

SYNONYM/ACRONYM: Cervical biopsy, endometrial biopsy.

COMMON USE: To visualize and assess the cervix and vagina related to suspected cancer or other disease.

AREA OF APPLICATION: Vagina and cervix.

CONTRAST: None.

DESCRIPTION: In this procedure, the vagina and cervix are viewed using a colposcope, a special binocular microscope and light system that magnifies the mucosal surfaces. Colposcopy is usually performed after suspicious Papanicolaou (Pap) test results or when suspected lesions cannot be visualized fully by the naked eye. The procedure is useful for identifying areas of cellular dysplasia and diagnosing cervical cancer because it provides the best view of the suspicious lesion, ensuring that the most representative area of the lesion is obtained for cytological analysis to confirm malignant changes. Colposcopy is also valuable for assessing women with a history of exposure to diethylstilbestrol (DES) in utero. The goal is to identify precursor changes in cervical tissue before the changes advance from benign or atypical cells to cervical cancer. Photographs (cervicography) can also be taken of the cervix.

This procedure is contraindicated for

-  Patients with bleeding disorders or receiving anticoagulant therapy, especially if cervical biopsy specimens are to be obtained ***because the biopsy site may not stop bleeding***
-  Women who are currently menstruating ***as bleeding may obscure abnormal findings***

INDICATIONS

- Evaluate the cervix after abnormal Pap smear
- Evaluate vaginal lesions

- Localize the area from which cervical biopsy samples should be obtained because such areas may not be visible to the naked eye
- Monitor conservatively treated cervical intraepithelial neoplasia
- Monitor women whose mothers took DES during pregnancy

POTENTIAL DIAGNOSIS

Normal findings in

- Normal appearance of the vagina and cervix
- No abnormal cells or tissues

Abnormal findings in

- Atrophic changes
- Cervical erosion
- Cervical intraepithelial neoplasia
- Infection
- Inflammation
- Invasive carcinoma
- Leukoplakia
- Papilloma, including condyloma

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inadequate cleansing of the cervix of secretions and medications.
- Scarring of the cervix.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Severe bleeding or the presence of feces, blood, or blood clots, which can interfere with visualization.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the uterus and cervix for disease.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed by a health-care provider (HCP), with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Explain to the patient that if a biopsy is performed, she may feel menstrual-like

cramping during the procedure and experience a minimal amount of bleeding.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Complications of the procedure may include bleeding, infection, and cardiac arrhythmias.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Obtain and record baseline vital signs.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer medications, as ordered, to reduce discomfort and to promote relaxation and sedation.
- ▶ Place the patient in the lithotomy position on the examining table and drape her. Cleanse the external genitalia with an antiseptic solution.
- ▶ If a Pap smear is performed, the vaginal speculum is inserted, using water as a lubricant.
- ▶ The cervix is swabbed with 3% acetic acid to remove mucus or any cream

medication and to improve the contrast between tissue types. The scope is positioned at the speculum and is focused on the cervix. The area is examined carefully, using light and magnification. Photographs can be taken for future reference.

- ▶ Tissues that appear abnormal or atypical undergo biopsy using a forceps inserted through the speculum. Bleeding, which is common after cervical biopsy, may be controlled by cautery, suturing, or application of silver nitrate or ferric subsulfate (Monsel's solution) to the site.
- ▶ The vagina is rinsed with sterile saline or water to remove the acetic acid and prevent burning after the procedure. If bleeding persists, a tampon may be inserted after removal of the speculum.
- ▶ Biopsy samples are placed in appropriately labeled containers with special preservative solution, and promptly transported to the laboratory.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Monitor the patient for signs of respiratory depression.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe the patient until the effects of the sedation, if ordered, have worn off.
- ▶ Instruct the patient to remove the vaginal tampon, if inserted, within 8 to 24 hr; after that time, the patient should wear pads if there is bleeding or drainage.

▶ If a biopsy was performed, inform the patient that a discharge may persist for a few days to a few weeks.

- ▶ Advise the patient to avoid strenuous exercise 8 to 24 hr after the procedure and to avoid douching and intercourse for about 2 wk or as directed by the HCP.
- ▶ Monitor for any bleeding.
- ▶ Instruct the patient to expect slight bleeding for 2 days after removal of biopsy specimens, but emphasize that persistent vaginal bleeding or abnormal vaginal discharge, an increasing amount of bleeding, abdominal pain, and fever must be reported to the HCP immediately.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy cervical, CT abdomen, culture viral, MRI abdomen, Pap smear, and US pelvis.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Complement C3 and Complement C4

SYNONYM/ACRONYM: C3 and C4.

COMMON USE: To assist in the diagnosis of immunological diseases, such as rheumatoid arthritis, and systemic lupus erythematosus (SLE), in which complement is consumed at an increased rate, or to detect inborn deficiency.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Immunoturbidimetric)

C3

Age	Conventional Units	SI Units (Conventional Units × 10)
Newborn	57–116 mg/dL	570–1,160 mg/L
6 mo–adult	74–166 mg/dL	740–1,660 mg/L
Adult	83–177 mg/dL	830–1,770 mg/L

C4

Age	Conventional Units	SI Units (Conventional Units × 10)
Newborn	10–31 mg/dL	100–310 mg/L
6 mo–6 yr	15–52 mg/dL	150–520 mg/L
7–12 yr	19–40 mg/dL	190–400 mg/L
13–15 yr	19–57 mg/dL	190–570 mg/L
16–18 yr	19–42 mg/dL	190–420 mg/L
Adult	12–36 mg/dL	120–360 mg/L

DESCRIPTION: Complement is a system of 25 to 30 distinct cell membrane and plasma proteins, numbered C1 through C9. Once activated, the proteins interact with each other in a specific sequence called the complement cascade. The classical pathway is triggered by antigen-antibody complexes and includes participation of all complement proteins C1 through C9. The alternate pathway occurs when C3, C5, and C9 are activated without participation of C1, C2, and C4 or the

presence of antigen-antibody complexes. Complement proteins act as enzymes that aid in the immunological and inflammatory response. The complement system is an important mechanism for the destruction and removal of foreign materials. Serum complement levels are used to detect autoimmune diseases. C3 and C4 are the most frequently assayed complement proteins, along with total complement.

Circulating C3 is synthesized in the liver and comprises 70% of

the complement system, but cells in other tissues can also produce C3. C3 is an essential activating protein in the classic and alternate complement cascades. It is decreased in patients with immunological diseases, in whom it is consumed at an increased rate. C4 is produced primarily in the liver but can also be produced by monocytes, fibroblasts, and macrophages. C4 participates in the classic complement pathway.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect genetic deficiencies
- Evaluate immunological diseases

POTENTIAL DIAGNOSIS

Normal	Acute
C4 and decreased C3	glomerulonephritis, membranous glomerulonephritis, immune complex diseases, SLE, C3 deficiency
Decreased C4 and normal C3	Immune complex diseases, cryoglobulinemia, C4 deficiency, hereditary angioedema
Decreased C4 and decreased C3	Immune complex diseases

Increased in Response to sudden increased demand

- C3 and C4
Acute-phase reactions
- C3
Amyloidosis
Cancer

Diabetes
Myocardial infarction
Pneumococcal pneumonia
Pregnancy
Rheumatic disease
Thyroiditis
Viral hepatitis

- C4
Certain malignancies

Decreased in

Related to overconsumption during immune response

- C3 and C4
Hereditary deficiency (*insufficient production*)
Liver disease (*insufficient production related to damaged liver cells*)
SLE
- C3
Chronic infection (bacterial, parasitic, viral)
Post-membranoproliferative glomerulonephritis
Post-streptococcal infection
Rheumatic arthritis
- C4
Angioedema (*hereditary and acquired*)
Autoimmune hemolytic anemia
Autoimmune thyroiditis
Cryoglobulinemia
Glomerulonephritis
Juvenile dermatomyositis
Meningitis (bacterial, viral)
Pneumonia
Streptococcal or staphylococcal sepsis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase C3 levels include cimetidine and cyclophosphamide.
- Drugs that may decrease C3 levels include danazol and phenytoin.
- Drugs that may increase C4 levels include cimetidine, cyclophosphamide, and danazol.
- Drugs that may decrease C4 levels include dextran and penicillamine.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing diseases of the immune system.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune system and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the

patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include anticardiolipin antibody, ANA, complement total, cryoglobulin, and ESR.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Complement, Total

SYNONYM/ACRONYM: Total hemolytic complement, CH₅₀, CH₁₀₀

COMMON USE: To evaluate immune diseases related to complement activity and follow up on a patient's response to therapy such as treatment for systemic lupus erythematosus (SLE).

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Quantitative hemolysis)

Conventional Units

25–110 CH₅₀ units/mL

SI Units (Conventional Units × 1)

25–110 CH₅₀ kU/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Acute-phase immune response (related to sudden response to increased demand)

Decreased in

- Autoimmune diseases (related to continuous demand)
- Autoimmune hemolytic anemia (related to consumption during hemolytic process)
- Burns (related to increased consumption from initiation of complement cascade)
- Cryoglobulinemia (related to increased consumption)
- Hereditary deficiency (related to insufficient production)

- Infections (*bacterial, parasitic, viral; related to increased consumption during immune response*)
- Liver disease (related to decreased production by damaged liver cells)
- Malignancy (related to consumption during cellular immune response)
- Membranous glomerulonephritis (related to consumption during cellular immune response)
- Rheumatoid arthritis (related to consumption during immune response)
- SLE (related to consumption during immune response)
- Trauma (related to consumption during immune response)
- Vasculitis (related to consumption during cellular immune response)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Complete Blood Count

SYNONYM/ACRONYM: CBC.

COMMON USE: To evaluate numerous conditions involving red blood cells, white blood cells, and platelets. This test is also used to indicate inflammation, infection, and response to chemotherapy.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube or Microtainer. Whole blood from a green-top (lithium or sodium heparin) tube may be submitted, but the following automated values may not be reported: white blood cell (WBC) count, WBC differential, platelet count, immature platelet fraction (IPF), and mean platelet volume.

NORMAL FINDINGS: (Method: Automated, computerized, multichannel analyzers. Many of these analyzers are capable of determining a five- or six-part WBC differential.) This battery of tests includes hemoglobin, hematocrit, red blood cell (RBC) count, RBC morphology, RBC indices, RBC distribution width index (RDWCV and RDWSD), platelet count, platelet size, IPF, WBC count, and WBC differential. The six-part automated WBC differential identifies and enumerates neutrophils, lymphocytes, monocytes, eosinophils, basophils, and immature granulocytes (IG), where IG represents the combined enumeration of promyelocytes, metamyelocytes, and myelocytes as both an absolute number and a percentage. The five-part WBC differential includes all but the IG parameters.

Hemoglobin

Age	Conventional Units	SI Units (Conventional Units × 10)
Cord blood	13.5–20.7 g/dL	135–207 mmol/L
0–1 wk	15.2–23.6 g/dL	152–236 mmol/L
2–3 wk	12.7–18.7 g/dL	127–187 mmol/L
1–2 mo	9.7–17.3 g/dL	97–173 mmol/L
3–11 mo	9.3–13.3 g/dL	93–133 mmol/L
1–5 yr	10.4–13.6 g/dL	104–136 mmol/L
6–8 yr	10.9–14.5 g/dL	109–145 mmol/L
9–14 yr	11.5–15.5 g/dL	115–155 mmol/L
15 yr–adult		
Male	13.2–17.3 g/dL	132–173 mmol/L
Female	11.7–15.5 g/dL	117–155 mmol/L
Older adult		
Male	12.6–17.4 g/dL	126–174 mmol/L
Female	11.7–16.1 g/dL	117–161 mmol/L

Note: See “Complete Blood Count, Hemoglobin” monograph for more detailed information.

Hematocrit

Age	Conventional Units (%)	SI Units (Conventional Units × 0.01)
Cord blood	42–62	0.42–0.62
0–1 wk	46–68	0.46–0.68
2–3 wk	40–56	0.4–0.56
1–2 mo	32–54	0.32–0.54
3 mo–5 yr	31–43	0.31–0.43

Female	185–335 × 10 ³ /microL	185–335 × 10 ⁹ /L	7.5–9.3	1.1–7.1
Adult/Older adult				
Male & Female	150–450 × 10 ³ /microL	150–450 × 10 ⁹ /L	7.1–10.2	1.1–7.1

Note: See “Complete Blood Count, Platelet Count” monograph for more detailed information. Platelet counts may decrease slightly with age.

DESCRIPTION: A complete blood count (CBC) is a group of tests used for basic screening purposes. It is probably the most widely ordered laboratory test. Results provide the enumeration of the cellular elements of the blood, measurement of red blood cell (RBC) indices, and determination of cell morphology by automation and evaluation of stained smears. The results can provide valuable diagnostic information regarding the overall health of the patient and the patient’s response to disease and treatment. Detailed information is found in monographs titled “Complete Blood Count, Hemoglobin”; “Complete Blood Count, Hematocrit”; “Complete Blood Count, RBC Indices”; “Complete Blood Count, RBC Morphology and Inclusions”;

“Complete Blood Count, RBC Count”; “Complete Blood Count, Platelet Count”; and “Complete Blood Count, WBC Count and Cell Differential.”

This procedure is contraindicated for: N/A

INDICATIONS

- Detect hematological disorder, neoplasm, leukemia, or immunological abnormality
- Determine the presence of hereditary hematological abnormality
- Evaluate known or suspected anemia and related treatment
- Monitor blood loss and response to blood replacement
- Monitor the effects of physical or emotional stress
- Monitor fluid imbalances or treatment for fluid imbalances

- Monitor hematological status during pregnancy
- Monitor progression of nonhematological disorders, such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor response to chemotherapy and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a general physical examination, especially on admission to a health-care facility or before surgery

POTENTIAL DIAGNOSIS

- See monographs titled “Complete Blood Count, Hemoglobin”; “Complete Blood Count, Hematocrit”; “Complete Blood Count, RBC Indices”; “Complete Blood Count, RBC Morphology and Inclusions”; “Complete Blood Count, RBC Count”; “Complete Blood Count, Platelet Count”; and “Complete Blood Count, WBC Count and Differential.”

Increased in

- See above-listed monographs.

Decreased in

- See above-listed monographs.

CRITICAL FINDINGS

Hemoglobin

Adults & children

- Less than 6.6 g/dL (SI: Less than 66 mmol/L)
- Greater than 20 g/dL (SI: Greater than 200 mmol/L)

Newborns

- Less than 9.5 g/dL (SI: Less than 95 mmol/L)
- Greater than 22.3 g/dL (SI: Greater than 223 mmol/L)

Hematocrit

Adults & children

- Less than 19.8% (SI: Less than 0.2 L/L)
- Greater than 60% (SI: Greater than 0.6 L/L)

Newborns

- Less than 28.5% (SI: Less than 0.28 L/L)
- Greater than 66.9% (SI: Greater than 0.67 L/L)

WBC Count (on Admission)

- Less than $2 \times 10^3/\text{microL}$ (SI: Less than $2 \times 10^9/\text{L}$)
- Greater than $30 \times 10^3/\text{microL}$ (SI: Greater than $30 \times 10^9/\text{L}$)

Platelet Count

- Less than $30 \times 10^3/\text{microL}$ (SI: Less than $30 \times 10^9/\text{L}$)
- Greater than $1,000 \times 10^3/\text{microL}$ (SI: Greater than $1,000 \times 10^9/\text{L}$)

Consideration may be given to verifying the critical findings before action is taken. Policies vary among facilities and may include requesting immediate recollection and retesting by the laboratory or retesting using a rapid Point of Care instrument at the bedside.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical

value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

The presence of abnormal cells, other morphological characteristics, or cellular inclusions may signify a potentially life-threatening or serious health condition and should be investigated. Examples are the presence of sickle cells, moderate numbers of spherocytes, marked schistocytosis, oval macrocytes, basophilic stippling, eosinophil count greater than 10%, monocytosis greater than 15%, nucleated RBCs (if patient is not an infant), malarial organisms, hypersegmented neutrophils, agranular neutrophils, blasts or other immature cells, Auer rods, Döhle bodies, marked toxic granulation, or plasma cells.

INTERFERING FACTORS

- Failure to fill the tube sufficiently (less than three-fourths full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens should be rejected for analysis.
- Elevated serum glucose or sodium levels may produce elevated mean corpuscular volume values because of swelling of erythrocytes.
- Recent transfusion history should be considered when evaluating the CBC.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating general health and the body's response to illness.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal, hematopoietic, immune, and respiratory systems as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be analyzed within 24 hr when stored at room temperature or within 48 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be

analyzed within 24 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 24 hr may contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and avoid use of tobacco.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include alveolar arterial ratio, biopsy bone marrow, blood gases, blood groups and antibodies, erythropoietin, ferritin, CBC hematocrit, CBC hemoglobin, CBC platelet count, CBC RBC count, CBC RBC indices, CBC RBC morphology, CBC WBC count and cell differential, iron/TIBC, lead, pulse oximetry, reticulocyte count, and US abdomen.
- ▶ Refer to the Gastrointestinal, Hematopoietic, Immune, and Respiratory systems tables at the end of the book for related tests by body system.

Complete Blood Count, Hematocrit

SYNONYM/ACRONYM: Packed cell volume (PCV), Hct.

COMMON USE: To evaluate anemia, polycythemia, and hydration status and to monitor therapy.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube, Microtainer, or capillary. Whole blood from a green-top (lithium or sodium heparin) tube may also be submitted.

NORMAL FINDINGS: (Method: Automated, computerized, multichannel analyzers)

Age	Conventional Units (%)	SI Units (Conventional Units × 0.01)
Cord blood	42–62	0.42–0.62
0–1 wk	46–68	0.46–0.68

1–2 mo	32–54	0.32–0.54
3 mo–5 yr	31–43	0.31–0.43
6–8 yr	33–41	0.33–0.41
9–14 yr	33–45	0.33–0.45
15 yr–adult		
Male	38–51	0.38–0.51
Female	33–45	0.33–0.45
Older adult		
Male	36–52	0.36–0.52
Female	34–46	0.34–0.46

DESCRIPTION: Blood consists of a liquid plasma portion and a solid cellular portion. The solid portion is comprised of red blood cells (RBCs), white blood cells (WBCs), and platelets. It is important to be able to assess whether there is a sufficient number of circulating RBCs to transport the required amount of oxygen throughout the body. The hematocrit (Hct) is a mathematical expression of the number of RBCs, or packed cell volume, expressed as a percentage of whole blood. For example, a packed cell volume, or Hct of 45% means that a 100-mL sample of blood contains 45 mL of packed RBCs, which would reflect an acceptable level of RBCs for a patient of any given age. The Hct depends primarily on the number of RBCs, however the average size of the RBCs influences Hct. Conditions that cause RBC size to be increased (e.g. swelling of the RBC due to change in osmotic pressure related to elevated sodium levels) may increase the Hct while conditions that result in smaller than normal RBCs (e.g. microcytosis related to iron deficiency anemia) may decrease the Hct. Hematocrit can

be estimated directly by centrifuging a sample of whole blood for a specific time period. As the blood spins it is separated into fractions. The RBC fraction is read against a scale. Most often the Hct is measured indirectly, by multiplying the RBC count and mean cell volume (MCV), using an automated cell counter. Hct can also be estimated by multiplying the hemoglobin by three.

The Hct level is part of the complete blood count (CBC). It is also frequently requested together with hemoglobin (Hgb) as an H&H. Hgb and Hct levels parallel each other and are the best determinant of the degree of anemia or polycythemia. *Polycythemia* is a term used in conjunction with conditions resulting from an abnormal increase in Hgb, Hct, and RBC counts. *Anemia* is a term associated with conditions resulting from an abnormal decrease in Hgb, Hct, and RBC counts. Results of the Hgb, Hct, and RBC counts should be evaluated simultaneously because the same underlying conditions affect this triad of tests similarly. The RBC count multiplied by 3 should approximate the Hgb concentration. The Hct

should be within 3 times the Hgb if the RBC population is normal in size and shape. The Hct plus 6 should approximate the first two figures of the RBC count within 3 (e.g., Hct is 40%; therefore $40 + 6 = 46$, and the RBC count should be 4.6 or in the range of 4.3 to 4.9). There are some cultural variations in Hgb and Hct (H&H) values. After the first decade of life, the mean Hgb in African Americans is 0.5 to 1 g lower than in whites. Mexican Americans and Asian Americans have higher H&H values than whites.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect hematological disorder, neoplasm, or immunological abnormality
- Determine the presence of hereditary hematological abnormality
- Evaluate known or suspected anemia and related treatment, in combination with Hgb
- Monitor blood loss and response to blood replacement, in combination with Hgb
- Monitor the effects of physical or emotional stress on the patient
- Monitor fluid imbalances or their treatment
- Monitor hematological status during pregnancy, in combination with Hgb
- Monitor the progression of nonhematological disorders such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially upon admission to a health-care facility or before surgery

POTENTIAL DIAGNOSIS

Increased in

- Burns (*related to dehydration; total blood volume is decreased, but RBC count remains the same*)
- Congestive heart failure (*when the underlying cause is anemia, the body responds by increasing production of RBCs with a corresponding increase in Hct*)
- Chronic obstructive pulmonary disease (*related to chronic hypoxia that stimulates production of RBC and a corresponding increase in Hct*)
- Dehydration (*total blood volume is decreased, but RBC count remains the same*)
- Erythrocytosis (*total blood volume remains the same, but RBC count is increased*)
- Hemoconcentration (*same effect as seen in dehydration*)
- High altitudes (*related to hypoxia that stimulates production of RBC and therefore increases Hct*)
- Polycythemia (*abnormal bone marrow response resulting in overproduction of RBC*)
- Shock

Decreased in

- Anemia (*overall decrease in RBC and corresponding decrease in Hct*)
- Blood loss (acute and chronic) (*overall decrease in RBC and corresponding decrease in Hct*)
- Bone marrow hyperplasia (*bone marrow failure that results in decreased RBC production*)
- Carcinoma (*anemia is often associated with chronic disease*)
- Cirrhosis (*related to accumulation of fluid*)
- Chronic disease (*anemia is often associated with chronic disease*)

- Fluid retention (*dilutional effect of increased blood volume while RBC count remains stable*)
- Hemoglobinopathies (*reduced RBC survival with corresponding decrease in Hgb*)
- Hemolytic disorders (e.g., hemolytic anemias, prosthetic valves) (*reduced RBC survival with corresponding decrease in Hct*)
- Hemorrhage (acute and chronic) (*related to loss of RBC that exceeds rate of production*)
- Hodgkin's disease (*bone marrow failure that results in decreased RBC production*)
- Incompatible blood transfusion (*reduced RBC survival with corresponding decrease in Hgb*)
- Intravenous overload (*dilutional effect*)
- Fluid retention (*dilutional effect of increased blood volume while RBC count remains stable*)
- Leukemia (*bone marrow failure that results in decreased RBC production*)
- Lymphomas (*bone marrow failure that results in decreased RBC production*)
- Nutritional deficit (*anemia related to dietary deficiency in iron, vitamins, folate needed to produce sufficient RBC; decreased RBC count with corresponding decrease in Hct*)
- Pregnancy (*related to anemia*)
- Renal disease (*related to decreased levels of erythropoietin, which stimulates production of RBCs*)
- Splenomegaly (*total blood volume remains the same, but spleen retains RBCs and Hct reflects decreased RBC count*)

- Greater than 60% (SI: Greater than 0.6 L/L)

Newborns

- Less than 28.5% (SI: Less than 0.28 L/L)
- Greater than 66.9% (SI: Greater than 0.67 L/L)

Consideration may be given to verifying the critical findings before action is taken. Policies vary among facilities and may include requesting immediate recollection and retesting by the laboratory or retesting using a rapid Point of Care instrument at the bedside.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Low Hct leads to anemia. Anemia can be caused by blood loss, decreased blood cell production, increased blood cell destruction, and hemodilution.

CRITICAL FINDINGS

Adults & children

- Less than 19.8% (SI: Less than 0.2 L/L)

Causes of blood loss include menstrual excess or frequency, gastrointestinal bleeding, inflammatory bowel disease, and hematuria. Decreased blood cell production can be caused by folic acid deficiency, vitamin B₁₂ deficiency, iron deficiency, and chronic disease. Increased blood cell destruction can be caused by a hemolytic reaction, chemical reaction, medication reaction, and sickle cell disease. Hemodilution can be caused by congestive heart failure, renal failure, polydipsia, and overhydration. Symptoms of anemia (due to these causes) include anxiety, dyspnea, edema, hypertension, hypotension, hypoxia, jugular venous distention, fatigue, pallor, rales, restlessness, and weakness. Treatment of anemia depends on the cause.

High Hct leads to polycythemia. Polycythemia can be caused by dehydration, decreased oxygen levels in the body, and an overproduction of RBCs by the bone marrow. Dehydration from diuretic use, vomiting, diarrhea, excessive sweating, severe burns, or decreased fluid intake decreases the plasma component of whole blood, thereby increasing the ratio of RBCs to plasma, and leads to a higher than normal Hct. Causes of decreased oxygen include smoking, exposure to carbon monoxide, high altitude, and chronic lung disease, which leads to a mild hemoconcentration of blood in the body to carry more oxygen to the body's tissues. An overproduction of RBCs by the bone marrow leads to polycythemia vera, which is a rare chronic myeloproliferative disorder that leads to a severe hemoconcentration of blood. Severe hemoconcentration can lead to thrombosis (spontaneous blood clotting). Symptoms of hemoconcentration include decreased pulse pressure and volume, loss of skin turgor, dry mucous membranes, headaches, hepatomegaly, low central venous pressure, orthostatic hypotension, pruritus (especially after a hot

bath), splenomegaly, tachycardia, thirst, tinnitus, vertigo, and weakness. Treatment of polycythemia depends on the cause. Possible interventions for hemoconcentration due to dehydration include intravenous fluids and discontinuance of diuretics if they are believed to be contributing to critically elevated Hct. Polycythemia due to decreased oxygen states can be treated by removal of the offending substance, such as smoke or carbon monoxide. Treatment includes oxygen therapy in cases of smoke inhalation, carbon monoxide poisoning, and desaturating chronic lung disease. Symptoms of polycythemic overload crisis include signs of thrombosis, pain and redness in the extremities, facial flushing, and irritability. Possible interventions for hemoconcentration due to polycythemia include therapeutic phlebotomy and intravenous fluids.

INTERFERING FACTORS

- Drugs and substances that may cause a decrease in Hct include those that induce hemolysis due to drug sensitivity or enzyme deficiency and those that result in anemia (see monograph titled “Complete Blood Count, RBC Count”).
- Some drugs may also affect Hct values by increasing the RBC count (see monograph titled “Complete Blood Count, RBC Count”).
- The results of RBC counts may vary depending on the patient's position: Hct can decrease when the patient is recumbent as a result of hemodilution and can increase when the patient rises as a result of hemoconcentration.
- Leaving the tourniquet in place for longer than 60 sec can falsely increase Hct levels by 2% to 5%.
- Traumatic venipuncture and hemolysis may result in falsely decreased Hct values.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may

yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.

- Clotted or hemolyzed specimens must be rejected for analysis.
- The results of a CBC should be carefully evaluated during transfusion or acute blood loss because the body is not in a state of homeostasis and values may be misleading. Considerations for draw times after transfusion include the type of product, the amount of product transfused, and the patient's clinical situation. Generally, specimens collected an hour after transfusion will provide an acceptable reflection of the effects of the transfused product. Measurements taken during a massive transfusion are an exception, providing essential guidance for therapeutic decisions during critical care.
- Abnormalities in the RBC size (macrocytes, microcytes) or shape (spherocytes, sickle cells) may alter Hct values, as in diseases and conditions including sickle cell anemia, hereditary spherocytosis, and iron deficiency.
- Elevated blood glucose or serum sodium levels may produce elevated Hct levels because of swelling of the erythrocytes.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating the body's blood cell volume status.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, gastrointestinal, hematopoietic, hepatobiliary, immune, and

respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top (EDTA) tube. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 24 hr when stored at room temperature or within 48 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 24 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 24 hr may

contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Nutritional therapy may be indicated for patients with increased Hct if iron levels are also elevated. Educate the patient with abnormally elevated iron values, as appropriate, on the importance of reading food labels. Patients with hemochromatosis or acute pernicious anemia should be educated to avoid foods rich in iron. Iron absorption is affected by numerous factors that may enhance or decrease absorption regardless of the original content of the iron-containing dietary source (see monograph titled “Iron”). Iron levels in foods can be increased if foods are cooked in cookware containing iron. Consumption of large amounts of alcohol damages the intestine and allows increased absorption of iron. A high intake of calcium and ascorbic acid also increases iron absorption. Iron absorption after a meal is also increased by factors in meat, fish, and poultry.
- ▶ **Nutritional Considerations:** Nutritional therapy may be indicated for patients with decreased Hct. Iron deficiency is the most common nutrient deficiency in the United States. Patients at risk (e.g., children, pregnant women, women of childbearing age, and low-income populations) should be instructed to include in their diet foods that are high in iron, such as meats (especially liver), eggs, grains, green

leafy vegetables, and multivitamins with iron. Educate the patient with abnormally elevated iron values, as appropriate, on the importance of reading food labels. Iron absorption is affected by numerous factors, enhancing or decreasing absorption regardless of the original content of the iron-containing dietary source (see monograph titled “Iron”). Iron absorption is affected by numerous factors, enhancing or decreasing absorption regardless of the original content of the iron-containing dietary source (see monograph titled “Iron”). Iron absorption is decreased by the absence (gastric resection) or diminished presence (use of antacids) of gastric acid. Phytic acids from cereals; tannins from tea and coffee; oxalic acid from vegetables; and minerals such as copper, zinc, and manganese interfere with iron absorption.

- ▶ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Educate the patient regarding access to nutritional counseling services. Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, CBC, CBC hemoglobin, CBC RBC indices, CBC RBC morphology, erythropoietin, ferritin, iron/TIBC, reticulocyte count, and US abdomen.
- ▶ Refer to the Cardiovascular, Gastrointestinal, Hematopoietic, Hepatobiliary, Immune, and Respiratory systems tables at the end of the book for related tests by body system.

Complete Blood Count, Hemoglobin

SYNONYM/ACRONYM: Hgb.

COMMON USE: To evaluate anemia, polycythemia, hydration status, and monitor therapy such as transfusion.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube, Microtainer, or capillary. Whole blood from a green-top (lithium or sodium heparin) tube may also be submitted.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 10)
Cord blood	13.5–20.7 g/dL	135–207 g/L
0–1 wk	15.2–23.6 g/dL	152–236 g/L
2–3 wk	12.7–18.7 g/dL	127–187 g/L
1–2 mo	9.7–17.3 g/dL	97–173 g/L
3–11 mo	9.3–13.3 g/dL	93–133 g/L
1–5 yr	10.4–13.6 g/dL	104–136 g/L
6–8 yr	10.9–14.5 g/dL	109–145 g/L
9–14 yr	11.5–15.5 g/dL	115–155 g/L
15 yr–adult		
Male	13.2–17.3 g/dL	132–173 g/L
Female	11.7–15.5 g/dL	117–155 g/L
Older adult		
Male	12.6–17.4 g/dL	126–174 g/L
Female	11.7–16.1 g/dL	117–161 g/L

DESCRIPTION: Hemoglobin (Hgb) is the main intracellular protein of erythrocytes. It carries oxygen (O_2) to and removes carbon dioxide (CO_2) from red blood cells (RBCs). It also serves as a buffer to maintain acid-base balance in the extracellular fluid. Each Hgb molecule consists of heme and globulin. Copper is a cofactor necessary for the enzymatic incorporation of iron molecules into heme. Heme contains iron and porphyrin molecules that have a high affinity for O_2 . The affinity of Hgb molecules for O_2 is

influenced by 2,3-diphosphoglycerate (2,3-DPG), a substance produced by anaerobic glycolysis to generate energy for the RBCs. When Hgb binds with 2,3-DPG, O_2 affinity decreases. The ability of Hgb to bind and release O_2 can be graphically represented by an oxyhemoglobin dissociation curve. The term *shift to the left* describes an increase in the affinity of Hgb for O_2 . Conditions that can cause this leftward shift include decreased body temperature, decreased 2,3-DPG, decreased CO_2 concentration, and

increased pH. Conversely, a *shift to the right* represents a decrease in the affinity of Hgb for O₂.

Conditions that can cause a rightward shift include increased body temperature, increased 2,3-DPG levels, increased CO₂ concentration, and decreased pH.

Hgb levels are a direct reflection of the O₂-combining capacity of the blood. It is the combination of heme and O₂ that gives blood its characteristic red color. RBC counts parallel the O₂-combining capacity of Hgb, but because some RBCs contain more Hgb than others, the relationship is not directly proportional. As CO₂ diffuses into RBCs, an enzyme called carbonic anhydrase converts the CO₂ into bicarbonate and hydrogen ions. Hgb that is not bound to O₂ combines with the free hydrogen ions, increasing pH. As this binding is occurring, bicarbonate is leaving the RBC in exchange for chloride ions. (For additional information about the relationship between the respiratory and renal components of this buffer system, see monograph titled “Blood Gases.”)

Hgb is included in the complete blood count (CBC). It is also frequently requested together with hemoglobin (Hgb) as an H&H. Hgb and Hct levels parallel each other and are frequently used to evaluate anemia.

Polycythemia is a condition resulting from an abnormal increase in Hgb, Hct, and RBC count. *Anemia* is a condition resulting from an abnormal decrease in Hgb, Hct, and RBC count. Results of the Hgb, Hct, and RBC count should be evaluated simultaneously because the same underlying conditions affect this triad of tests similarly. The RBC count multiplied by 3 should

approximate the Hgb concentration. The Hct should be within three times the Hgb if the RBC population is normal in size and shape. The Hct plus 6 should approximate the first two figures of the RBC count within 3 (e.g., Hct is 40%; therefore $40 + 6 = 46$, and the RBC count should be 4.6 or in the range of 4.3 to 4.9).

There are some cultural variations in Hgb and Hct (H&H) values. After the first decade of life, the mean Hgb in African Americans is 0.5 to 1 g lower than in whites. Mexican Americans and Asian Americans have higher Hgb and H&H values than whites.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect hematological disorder, neoplasm, or immunological abnormality
- Determine the presence of hereditary hematological abnormality
- Evaluate known or suspected anemia and related treatment, in combination with Hct
- Monitor blood loss and response to blood replacement, in combination with Hct
- Monitor the effects of physical or emotional stress on the patient
- Monitor fluid imbalances or their treatment
- Monitor hematological status during pregnancy, in combination with Hct
- Monitor the progression of non-hematological disorders, such as chronic obstructive pulmonary disease (COPD), malabsorption syndromes, cancer, and renal disease
- Monitor response to drugs or chemotherapy and evaluate undesired

reactions to drugs that may cause blood dyscrasias

- Provide screening as part of a CBC in a general physical examination, especially upon admission to a health care facility or before surgery

C POTENTIAL DIAGNOSIS

Increased in

- Burns (*related to dehydration; total blood volume is decreased, but RBC count remains the same*)
- Congestive heart failure (*when the underlying cause is anemia, the body will respond by increasing production of RBCs; with a responding increase in Hct*)
- COPD (*related to chronic hypoxia that stimulates production of RBCs and a corresponding increase in Hgb*)
- Dehydration (*total blood volume is decreased, but RBC count remains the same*)
- Erythrocytosis (*total blood volume remains the same, but RBC count is increased*)
- Hemoconcentration (*same effect as seen in dehydration*)
- High altitudes (*related to hypoxia that stimulates production of RBCs and therefore increases Hgb*)
- Polycythemia vera (*abnormal bone marrow response resulting in overproduction of RBCs*)
- Shock

Decreased in

- Anemias (*overall decrease in RBCs and corresponding decrease in Hgb*)
- Blood loss (acute and chronic) (*overall decrease in RBC and corresponding decrease in Hct*)
- Bone marrow hyperplasia (*bone marrow failure that results in decreased RBC production*)

- Carcinoma (*anemia is often associated with chronic disease*)
- Cirrhosis (*related to accumulation of fluid*)
- Chronic disease (*anemia is often associated with chronic disease*)
- Fluid retention (*dilutional effect of increased blood volume while RBC count remains stable*)
- Hemoglobinopathies (*reduced RBC survival with corresponding decrease in Hgb*)
- Hemolytic disorders (e.g. hemolytic anemias, prosthetic valves) (*reduced RBC survival with corresponding decrease in Hct*)
- Hemorrhage (acute and chronic) (*overall decrease in RBCs and corresponding decrease in Hgb*)
- Hodgkin's disease (*bone marrow failure that results in decreased RBC production*)
- Incompatible blood transfusion (*reduced RBC survival with corresponding decrease in Hgb*)
- Intravenous overload (*dilutional effect*)
- Leukemia (*bone marrow failure that results in decreased RBC production*)
- Lymphomas (*bone marrow failure that results in decreased RBC production*)
- Nutritional deficit (*anemia related to dietary deficiency in iron, vitamins, folate needed to produce sufficient RBCs; decreased RBC count with corresponding decrease in Hgb*)
- Pregnancy (*related to anemia*)
- Renal disease (*related to decreased levels of erythropoietin, which stimulates production of RBCs*)
- Splenomegaly (*total blood volume remains the same, but spleen retains RBCs and Hgb reflects decreased RBC count*)

CRITICAL FINDINGS **Adults & children**

- Less than 6.6 g/dL (SI: Less than 66 g/L)
- Greater than 20 g/dL (SI: Greater than 200 g/L)

Newborns

- Less than 9.5 g/dL (SI: Less than 95 g/L)
- Greater than 22.3 g/dL (SI: Greater than 223 g/L)

Consideration may be given to verifying the critical findings before action is taken. Policies vary among facilities and may include requesting immediate recollection and retesting by the laboratory or retesting using a rapid Point of Care instrument at the bedside.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Low Hgb leads to anemia. Anemia can be caused by blood loss, decreased blood cell production, increased blood cell destruction, and hemodilution. Causes of blood loss include menstrual excess or frequency, gastrointestinal bleeding, inflammatory bowel disease, and hematuria. Decreased blood cell production can be caused by folic acid deficiency, vitamin B₁₂ deficiency, iron deficiency, and chronic disease. Increased blood cell destruction can be caused by a hemolytic reaction, chemical reaction, medication reaction, and sickle cell disease. Hemodilution can be caused by congestive heart failure, renal failure, polydipsia, and overhydration. Symptoms of anemia (due to these causes) include anxiety, dyspnea, edema, fatigue, hypertension, hypotension, hypoxia, jugular venous distention, pallor, rales, restlessness, and weakness. Treatment of anemia depends on the cause.

High Hgb leads to polycythemia. Polycythemia can be caused by dehydration, decreased oxygen levels in the body, and an overproduction of RBCs by the bone marrow. Dehydration from diuretic use, vomiting, diarrhea, excessive sweating, severe burns, or decreased fluid intake decreases the plasma component of whole blood, thereby increasing the ratio of RBCs to plasma, and leads to a higher than normal Hgb. Causes of decreased oxygen include smoking, exposure to carbon monoxide, high altitude, and chronic lung disease, which leads to a mild hemoconcentration of blood in the body to carry more oxygen to the body's tissues. An overproduction of RBCs by the bone marrow leads to polycythemia vera, which is a rare chronic myeloproliferative disorder that leads to a severe hemoconcentration of blood. Severe hemoconcentration can lead to thrombosis (spontaneous blood clotting). Symptoms of hemoconcentration include decreased

pulse pressure and volume, loss of skin turgor, dry mucous membranes, headaches, hepatomegaly, low central venous pressure, orthostatic hypotension, pruritus (especially after a hot bath), splenomegaly, tachycardia, thirst, tinnitus, vertigo, and weakness. Treatment of polycythemia depends on the cause. Possible interventions for hemoconcentration due to dehydration include intravenous fluids and discontinuance of diuretics if they are believed to be contributing to critically elevated Hgb. Polycythemia due to decreased oxygen states can be treated by removal of the offending substance, such as smoke or carbon monoxide. Treatment includes oxygen therapy in cases of smoke inhalation, carbon monoxide poisoning, and desaturating chronic lung disease. Symptoms of polycythemic overload crisis include signs of thrombosis, pain and redness in extremities, facial flushing, and irritability. Possible interventions for hemoconcentration due to polycythemia include therapeutic phlebotomy and intravenous fluids.

INTERFERING FACTORS

- Drugs and substances that may cause a decrease in Hgb include those that induce hemolysis due to drug sensitivity or enzyme deficiency and those that result in anemia (see monograph titled “Complete Blood Count, RBC Count”).
- Some drugs may also affect Hgb values by increasing the RBC count (see monograph titled “Complete Blood Count, RBC Count”).
- The results of RBC counts may vary depending on the patient's position: Hgb can decrease when the patient is recumbent as a result of hemodilution and can increase when the patient rises as a result of hemoconcentration.
- Use of the nutraceutical liver extract is strongly contraindicated

in iron-storage disorders, such as hemochromatosis, because it is rich in heme (the iron-containing pigment in Hgb).

- A severe copper deficiency may result in decreased Hgb levels.
- Cold agglutinins may falsely increase the mean corpuscular Hgb concentration (MCHC) and decrease the RBC count, affecting Hgb values. This can be corrected by warming the blood or replacing the plasma with warmed saline and repeating the analysis.
- Leaving the tourniquet in place for longer than 60 sec can falsely increase Hgb levels by 2% to 5%.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Clotted or hemolyzed specimens must be rejected for analysis.
- Care should be taken in evaluating the Hgb during the first few hours after transfusion or acute blood loss because the value may appear to be normal and may not be a reliable indicator of anemia or therapeutic response to treatment.
- Abnormalities in the RBC size (macrocytes, microcytes) or shape (spherocytes, sickle cells) may alter Hgb values, as in diseases and conditions including sickle cell anemia, hereditary spherocytosis, and iron deficiency.
- Lipemia will falsely increase the Hgb measurement, also affecting the mean corpuscular volume (MCV) and MCHC. This can be corrected by replacing the plasma with saline, repeating the measurement, and manually correcting the Hgb, MCH, and MCHC using specific mathematical formulas.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fatigue (<i>Related to decreased oxygenation associated with a decreased number of red blood cells</i>)	Verbalization of fatigue; altered ability to perform activities of daily living due to lack of energy; shortness of breath with exertion; increasingly frequent rest periods; presence of fatigue after sleep; inability to adhere to daily routine; altered level of concentration; complaints of tiredness	Monitor and trend CBC, HGB, HCT; monitor for shortness of breath; use oxygen administration and pulse oximetry as appropriate; assess ability to perform self-care; assess nutritional intake; encourage frequent rest periods; teach techniques for conserving energy expenditure; administer blood and blood products as ordered; monitor urine, stool, and sputum for bleeding; assess for medical or psychological factors contributing to fatigue; prioritize and bundle activities to conserve energy and decrease fatigue; administer prescribed erythropoietin
Bleeding (<i>Related to malfunction of bone marrow</i>)	Altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; capillary refill greater than 3 sec; cool extremities	Monitor and trend platelet count; increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; administer stool softeners as needed; monitor and assess stool, urine, sputum, gums, nose, for blood; coordinate laboratory draws to decrease frequency of venipuncture; institute bleeding precautions (avoid IM injections, prevent trauma, be gentle with oral care and suctioning, avoid use of a sharp razor); administer prescribed medications; assess diet for iron-rich foods, and foods with vitamin K

(table continues on page 492)

Problem	Signs & Symptoms	Interventions
Activity (<i>Related to decreased oxygen-carrying capacity of the blood secondary to anemia; decreased number of RBCs</i>)	Weakness; fatigue; shortness of breath with activity; dizziness; palpitations; headache; verbalization of difficulty with activity tolerance	Assess for fall risk and implement strategies commensurate with level of risk; administer prescribed oxygen; use pulse oximetry; administer blood and blood products as ordered; monitor for transfusion reaction; coordinate episodes of activity with rest periods; increase activity gradually as anemia resolves
Knowledge (<i>Related to lack of resources; unfamiliar with disease process; complexity of disease process and treatment; new disease process</i>)	Asks multiple questions; asks too few questions; inaccurate verbalization of information; noncompliance or inaccurate treatment choices	Assess understanding of anemia; assess understanding of iron deficiency; assess current level of knowledge regarding disease process; explain the functions of RBCs within the body in relation to overall health; examine dietary selections; teach how to choose foods that will support RBC formation; teach about the importance of taking prescribed iron or folic acid

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating the amount of hemoglobin in the blood to assist in diagnosis and monitor therapy.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, gastrointestinal, hematopoietic, hepatobiliary, immune, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL lavender-top (EDTA) tube. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 24 hr when stored at room temperature or within 48 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 24 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 24 hr may contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- ▶ The results of a CBC should be carefully evaluated during transfusion or acute blood loss because the body is not in a state of homeostasis and values may be misleading. Considerations for draw times after transfusion include the type of product, the amount of product transfused, and the patient's clinical situation. Generally, specimens collected an hour after transfusion will provide an acceptable reflection of the effects of the transfused product. Measurements taken during a massive transfusion are an exception, providing essential guidance for therapeutic decisions during critical care.
- ▶ Recognize anxiety related to test results, and assess the color of the patient's skin as pallor is an indication of poor tissue perfusion. Inform the patient, as appropriate, that oxygen or blood product transfusion may be necessary to alleviate some of the symptoms the patient is experiencing due to the effects of the anemia. Frequently assess vital signs and explain to the patient that elevating the head of the bed may reduce difficulty in breathing. Educate the patient regarding access to nutritional counseling services.
- ▶ **Nutritional Considerations:** Nutritional therapy may be indicated for patients with increased Hgb if iron levels are also elevated. Educate the patient with abnormally elevated iron values, as appropriate, on the importance of reading food labels. Patients with hemochromatosis or acute pernicious anemia should be educated to avoid foods rich in iron. Iron absorption is affected by numerous factors that may enhance or decrease absorption regardless of the original content of the iron-containing dietary source (see monograph titled "Iron"). Iron levels in foods can be increased if foods are cooked in cookware containing iron. Consumption of large amounts of alcohol damages the intestine and allows increased absorption of iron. A high intake of calcium and ascorbic acid also

increases iron absorption. Iron absorption after a meal is also increased by factors in meat, fish, and poultry.

- ▶ **Nutritional Considerations:** Nutritional therapy may be indicated for patients with decreased Hgb. Iron deficiency is the most common nutrient deficiency in the United States. Patients at risk (e.g., children, pregnant women, women of childbearing age, and low-income populations) should be instructed to include in their diet foods that are high in iron, such as meats (especially liver), eggs, grains, green leafy vegetables, and multivitamins with iron. Educate the patient with abnormally elevated iron values, as appropriate, on the importance of reading food labels. Iron absorption is affected by numerous factors, enhancing or decreasing absorption regardless of the original content of the iron containing dietary source (see monograph titled "Iron"). Iron absorption is decreased by the absence (gastric resection) or diminished presence (use of antacids) of gastric acid. Phytic acids from cereals; tannins from tea and coffee; oxalic acid from vegetables; and minerals such as copper, zinc, and manganese interfere with iron absorption.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Educate the patient regarding access to nutritional counseling services. Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that activity tolerance will increase as anemia resolves
- ▶ States understanding that erythropoietin replacement therapy will be needed until anemia resolves

Skills

- ▶ Demonstrates proficiency in the self-administration of erythropoietin
- ▶ Demonstrates proficiency in the self-administration of iron or folic acid supplements

Attitude

- ▶ Discusses the risk and benefits associated with blood transfusion
- ▶ Complies with the request to include dietary foods high in iron

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, biopsy lymph node, biopsy kidney, blood groups and antibodies, CBC, CBC hematocrit, Coombs' antiglobulin, CT thoracic, erythropoietin, fecal analysis (occult blood), ferritin, gallium scan, haptoglobin, hemoglobin electrophoresis, iron/TIBC, lymphangiogram, Meckel's diverticulum scan, reticulocyte count, sickle cell screen, and US abdomen.
- ▶ Refer to the Cardiovascular, Gastrointestinal, Hematopoietic, Hepatobiliary, Immune, and Respiratory systems tables at the end of the book for related tests by body system.

Complete Blood Count, Platelet Count

SYNONYM/ACRONYM: Thrombocytes.

COMMON USE: To assist in diagnosing and evaluating treatment for blood disorders such as thrombocytosis and thrombocytopenia and to evaluate preprocedure or preoperative coagulation status.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Automated, computerized, multichannel analyzers)

Age	Platelet Count*	SI Units (Conventional Units × 1)	MPV (fL)	IPF (%)
Newborn				
Male	150–350 × 10 ³ /microL	150–350 × 10 ⁹ /L	7.1–10.2	1.1–7.1
Female	235–345 × 10 ³ /microL	235–345 × 10 ⁹ /L	7.3–10.2	1.1–7.1
1–2 mo				
Male	275–565 × 10 ³ /microL	275–565 × 10 ⁹ /L	7.1–11.3	1.1–7.1
Female	295–615 × 10 ³ /microL	295–615 × 10 ⁹ /L	7.4–9.7	1.1–7.1

Adult/ Older adult				
Male & Female	150–450 × 10 ³ /microL	150–450 × 10 ⁹ /L	7.1–10.2	1.1–7.1

Note: Platelet counts may decrease slightly with age.

*Conventional units.

MPV = mean platelet volume.

DESCRIPTION: *Platelets* are non-nucleated, cytoplasmic, round or oval disks formed by budding off of large, multinucleated cells (megakaryocytes). Platelets have an essential function in coagulation, hemostasis, and blood thrombus formation. Activated platelets release a number of procoagulant factors, including thromboxane, a very potent platelet activator, from storage granules. These factors enter the circulation and activate other platelets and the cycle continues. The activated platelets aggregate at the site of vessel injury, and at this stage of hemostasis the glycoprotein IIb/IIIa receptors on the activated platelets bind fibrinogen, causing the platelets to stick together and form a plug. Coagulation must be localized to the site of vessel wall injury, or the growing platelet plug would eventually occlude the affected vessel. The fibrinolytic system, under normal circumstances, begins to work, once fibrin begins to form, to ensure coagulation is limited to the appropriate site. *Thrombocytosis* is an increase in platelet count. In reactive thrombocytosis, the increase is transient and short-lived, and it usually does not pose a health risk. One exception may be reactive thrombocytosis occurring after coronary bypass surgery. This circumstance has been identified as an important risk factor for postoperative infarction and thrombosis. The term *thrombocythemia* describes platelet increases associated with chronic myeloproliferative disorders; *thrombocytopenia* describes platelet counts of less than $140 \times 10^3/\text{microL}$. Decreased platelet counts occur whenever the body's need for platelets exceeds the rate of platelet production; this circumstance will

arise if production rate decreases or platelet loss increases. The severity of bleeding is related to platelet count as well as platelet function. Platelet counts can be within normal limits, but the patient may exhibit signs of internal bleeding; this circumstance usually indicates an anomaly in platelet function. Abnormal findings by automated cell counters may indicate the need to review a smear of peripheral blood for platelet estimate. Abnormally large or giant platelets may result in underestimation of automated counts by 30% to 50%. A large discrepancy between the automated count and the estimate requires that a manual count be performed. Platelet clumping may result in the underestimation of the platelet count. Clumping may be detected by the automated cell counter or upon microscopic review of a blood smear. A citrated platelet count, performed on a specimen collected in a blue-top tube, can be performed to obtain an accurate platelet count from patients who demonstrate platelet clumping in EDTA-preserved samples.

Thrombopoiesis or platelet production is reflected by the measurement of the immature platelet fraction (IPF). This parameter can be correlated to the total platelet count in the investigation of platelet disorders. A low platelet count with a low IPF can indicate a disorder of platelet production (e.g., drug toxicity, aplastic anemia or bone marrow failure of another cause), whereas a low platelet count with an increased IPF might indicate platelet destruction or abnormally high platelet consumption (e.g., mechanical destruction, disseminated intravascular coagulation

[DIC], idiopathic thrombocytopenic purpura [ITP], thrombotic thrombocytopenic purpura [TTP]).

Platelet size, reflected by mean platelet volume (MPV), and cellular age are inversely related; that is, younger platelets tend to be larger. An increase in MPV indicates an increase in platelet turnover. Therefore, in a healthy patient, the platelet count and MPV have an inverse relationship. Abnormal platelet size may also indicate the presence of a disorder. MPV and platelet distribution width (PDW) are both increased in ITP. MPV is also increased in May-Hegglin anomaly, Bernard-Soulier syndrome, myeloproliferative disorders, hyperthyroidism, and pre-eclampsia. MPV is decreased in Wiskott-Aldrich syndrome, septic thrombocytopenia, and hypersplenism.

Platelets have receptor sites that are essential for normal platelet function and activation. Drugs such as clopidogrel, abciximab (Reopro), eptifibatid (Integrilin), and tirofiban block these receptor sites and inhibit platelet function. Aspirin also can affect platelet function by the irreversible inactivation of a crucial cyclooxygenase (COX) enzyme. Medications like clopidogrel (Plavix) and aspirin are prescribed to prevent heart attack, stroke, and blockage of coronary stents. Studies have confirmed that up to 30% of patients receiving these medications may be nonresponsive. There are several commercial test systems that can assess platelet function and provide information that confirms platelet response. Platelet response testing helps ensure alternative or additional platelet therapy is instituted, if necessary.

The test results can also be used preoperatively to determine whether antiplatelet medications have been sufficiently cleared from the patient's circulation such that surgery can safely be performed without risk of excessive bleeding. Thromboxane A₂ is a potent stimulator of platelet activation. 11-dehydrothromboxane B₂ is the stable, inactive product of thromboxane A₂ metabolism, released by activated platelets. Urine levels of 11-dehydrothromboxane B₂ can be used to monitor response to aspirin therapy.

The metabolism of many commonly prescribed medications is driven by the cytochrome P₄₅₀ (CYP₄₅₀) family of enzymes. Genetic variants can alter enzymatic activity that results in a spectrum of effects ranging from the total absence of drug metabolism to ultrafast metabolism. Impaired drug metabolism can prevent the intended therapeutic effect or even lead to serious adverse drug reactions. Poor metabolizers (PM) are at increased risk for drug-induced side effects due to accumulation of drug in the blood, while ultrarapid metabolizers (UM) require a higher than normal dosage because the drug is metabolized over a shorter duration than intended. Other genetic phenotypes used to report CYP₄₅₀ results are intermediate metabolizer (IM) and extensive metabolizer (EM). CYP_{2C19} is a gene in the CYP₄₅₀ family that metabolizes drugs such as clopidogrel (Plavix). Genetic testing can be performed on blood samples submitted to a laboratory. Testing for the most common genetic variants of CYP_{2C19} is used to predict altered enzyme activity and

anticipate the most effective therapeutic plan. The test method commonly used is polymerase chain reaction. Counseling and informed written consent are generally required for genetic testing.

This procedure is contraindicated for: N/A

INDICATIONS

- Confirm an elevated platelet count (thrombocytosis), which can cause increased clotting
- Confirm a low platelet count (thrombocytopenia), which can be associated with bleeding
- Identify the possible cause of abnormal bleeding, such as epistaxis, hematoma, gingival bleeding, hematuria, and menorrhagia
- Provide screening as part of a complete blood count (CBC) in a general physical examination, especially upon admission to a health-care facility or before surgery

POTENTIAL DIAGNOSIS

Increased in

Conditions that involve inflammation activate and increase the number of circulating platelets:

- Acute infections
- After exercise (transient)
- Anemias (posthemorrhagic, hemolytic, iron-deficiency) (**bone marrow response to anemia; platelet formation is unaffected by iron deficiency**)
- Chronic heart disease
- Cirrhosis
- Essential thrombocythemia
- Leukemias (chronic)
- Malignancies (carcinoma, Hodgkin's, lymphomas)
- Pancreatitis (chronic)

- Polycythemia vera (**hyperplastic bone marrow response in all cell lines**)
- Rebound recovery from thrombocytopenia (**initial response**)
- Rheumatic fever (acute)
- Rheumatoid arthritis
- Splenectomy (2 mo postprocedure) (**normal function of the spleen is to cull aging cells from the blood; without the spleen, the count increases**)
- Surgery (2 wk postprocedure)
- Trauma
- Tuberculosis
- Ulcerative colitis

Decreased in

Decreased in (as a result of megakaryocytic hypoproliferation)

- Alcohol toxicity
- Aplastic anemia
- Congenital states (Fanconi's syndrome, May-Hegglin anomaly, Bernard-Soulier syndrome, Wiskott-Aldrich syndrome, Gaucher's disease, Chédiak-Higashi syndrome)
- Drug toxicity
- Prolonged hypoxia

Decreased in (as a result of ineffective thrombopoiesis)

- Ethanol abuse without malnutrition
- Iron-deficiency anemia
- Megaloblastic anemia (B₁₂/folate deficiency)
- Paroxysmal nocturnal hemoglobinuria
- Thrombopoietin deficiency
- Viral infection

Decreased in (as a result of bone marrow replacement)

- Lymphoma
- Granulomatous infections
- Metastatic carcinoma
- Myelofibrosis

*Increased in***Increased destruction in
(as a result of increased loss/
consumption)**

- Contact with foreign surfaces (dialysis membranes, artificial organs, grafts, prosthetic devices)
- Disseminated intravascular coagulation
- Extensive transfusion
- Severe hemorrhage
- Thrombotic thrombocytopenic purpura
- Uremia

**Increased destruction in
(as a result of immune reaction)**

- Antibody/human leukocyte antigen reactions
- Hemolytic disease of the newborn (*target is platelets instead of RBCs*)
- Idiopathic thrombocytopenic purpura
- Refractory reaction to platelet transfusion

**Increased destruction in
(as a result of immune reaction
secondary to infection)**

- Bacterial infections
- Burns
- Congenital infections (cytomegalovirus, herpes, syphilis, toxoplasmosis)
- Histoplasmosis
- Malaria
- Rocky Mountain spotted fever

**Increased destruction in
(as a result of other causes)**

- Radiation
- Splenomegaly caused by liver disease

CRITICAL FINDINGS

- Less than $30 \times 10^3/\text{microL}$ (SI: Less than $30 \times 10^9/\text{L}$)
- Greater than $1,000 \times 10^3/\text{microL}$ (SI: Greater than $1,000 \times 10^9/\text{L}$)

Consideration may be given to verifying the critical findings before action is taken. Policies vary among facilities and may include requesting immediate recollection and retesting by the laboratory or retesting using a rapid Point of Care instrument at the bedside.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Critically low platelet counts can lead to brain bleeds or GI hemorrhage, which can be fatal. Some signs and symptoms of decreased platelet count include spontaneous nose bleeds or bleeding from the gums, bruising easily, prolonged bleeding from minor cuts and scrapes, or bloody stool. Possible interventions for decreased platelet count may include transfusion of platelets or changes in anticoagulant therapy.

INTERFERING FACTORS

- Drugs that may decrease platelet counts include acetohepamide, acetophenazine, amphotericin B, antazoline, anticonvulsants, antimony compounds, apronolide, arsenicals, azathioprine, barbiturates, benzene, busulfan, butaperazine, chlordane, chlorophenothane, chlortetracycline, dactinomycin, dextromethorphan, diethylstilbestrol, ethinamate, ethoxzolamide, floxuridine, hexachlorobenzene, hydantoin derivatives, hydroflumethiazide, hydroxychloroquine, iproniazid, mechlorethamine, mefenamic acid, mepazine, miconazole, mitomycin, nitrofurantoin, novobiocin, nystatin, phenolphthalein, phenothiazine, pipamazine, plicamycin, procarbazine, pyrazolones, streptomycin, sulfonamides, tetracycline, thiabendazole, thiouracil, tolazamide, tolazoline, tolbutamide, trifluoperazine, and urethane.
 - Drugs that may increase platelet counts include glucocorticoids.
 - X-ray therapy may also decrease platelet counts.
 - The results of blood counts may vary depending on the patient's position.
- Platelet counts can decrease when the patient is recumbent, as a result of hemodilution, and can increase when the patient rises, as a result of hemoconcentration.
 - Platelet counts normally increase under a variety of stressors, such as high altitudes or strenuous exercise.
 - Platelet counts are normally decreased before menstruation and during pregnancy.
 - Leaving the tourniquet in place for longer than 60 sec can affect the results.
 - Traumatic venipunctures may lead to erroneous results as a result of activation of the coagulation sequence.
 - Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
 - Hemolysis or clotted specimens are reasons for rejection.
 - CBC should be carefully evaluated after transfusion or acute blood loss because the value may appear to be normal.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Protection (<i>Related to decreased platelet count; bleeding risk</i>)	Ease of bruising; blood in urine, stool, sputum, nosebleed, bleeding gums; presence of hematoma or petechiae; headache; vision changes	Assess for bruising, petechiae, hematoma; monitor and trend platelet count; administer blood or blood products, platelets; administer stool softeners; administer prescribed corticosteroids; increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; assess stool, urine, sputum, gums, nose, for blood; coordinate laboratory draws to decrease

Problem	Signs & Symptoms	Interventions
		frequency of venipuncture; institute bleeding precautions avoid IM injections, prevent trauma, be gentle with oral care and suctioning avoid use of a sharp razor); administer prescribed medications (IV immunoglobulin, recombinant interleukin, anti-D immune globulin)
Tissue perfusion (cerebral, peripheral, renal) <i>(Related to altered blood flow associated with platelet clumping)</i>	Confusion; altered mental status; headaches; dizziness; visual disturbances; hypotension; cool extremities; capillary refill greater than 3 sec; weak pedal pulses; altered level of consciousness; decreased urine output	Monitor blood pressure; assess for dizziness; check skin temperature for warmth; assess capillary refill; assess pedal pulses; monitor level of consciousness; monitor urine output to be in excess of 30 mL/hr; ensure adequate fluid intake or administer intravenous fluids as ordered
Pain <i>(Related to joint disturbances associated with bleeding; bleeding into the tissues)</i>	Expression of pain, facial grimace, moaning, crying; report of pain	Assess level of pain and identify pain characteristics (what makes it better or worse); use a foot cradle to keep pressure off of legs; support joints with pillows; use socks to keep feet warm; administer prescribed analgesics; assess effectiveness of analgesics and collaborate with HCP to provide adequate pain management
Confusion <i>(Related to decreased tissue perfusion secondary to platelet clumping and altered blood flow)</i>	Disorganized thinking, restless, irritable, altered concentration and attention span, changeable mental function over the day, hallucinations; altered attention span; inability to follow directions; disoriented to person, place, time, and purpose; inappropriate affect	Treat the medical condition; monitor and trend platelet count; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or restraints; administer prescribed medications (IV immunoglobulin, recombinant interleukin, anti-D immune globulin)

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing, evaluating, and monitoring bleeding disorders.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic and immune systems, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen,

- date, and time of collection. Perform a venipuncture. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 24 hr when stored at room temperature or within 48 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 24 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ The results of a CBC should be carefully evaluated during transfusion or acute blood loss because the body is not in a state of homeostasis and values may be misleading. Considerations for draw times after transfusion include the type of product, the amount of product transfused, and the patient's clinical situation. Generally, specimens collected an hour after transfusion will provide an acceptable reflection of the effects of the transfused product. Measurements taken during a massive transfusion are an exception, providing essential guidance for therapeutic decisions during critical care.
- ▶ **Nutritional Considerations:** Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and avoid the use of tobacco.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor

progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to report bleeding from any areas of the skin or mucous membranes.
- ▶ Inform the patient of the importance of periodic laboratory testing if he or she is taking an anticoagulant.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States the importance of taking a stool softener to prevent straining while having a bowel movement
- ▶ States the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation,

avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections

Skills

- ▶ Identifies symptoms of bleeding that should be reported to the HCP
- ▶ Identifies pain management therapy that provides the best pain relief

Attitude

- ▶ Complies with the request to refrain from participating in at-risk activities that could cause trauma and bleeding
- ▶ Complies with the request to take stool softeners to prevent constipation and bleeding

RELATED MONOGRAPHS:

- ▶ Related tests include antiarrhythmic drugs (quinidine), biopsy bone marrow, bleeding time, blood groups and antibodies, clot retraction, coagulation factors, CBC, CBC RBC morphology and inclusions, CBC WBC count and differential, CT angiography, CT brain, FDP, fibrinogen, PTT, platelet antibodies, procalcitonin, PT/INR, and US pelvis.
- ▶ Refer to the Hematopoietic and Immune systems tables at the end of the book for related tests by body system.

Complete Blood Count, RBC Count

SYNONYM/ACRONYM: RBC.

COMMON USE: To evaluate the number of circulating red cells in the blood toward diagnosing disease and monitoring therapeutic treatment. Variations in the number of cells is most often seen in anemias, cancer, and hemorrhage.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Automated, computerized, multichannel analyzers)

Age	Conventional Units (10^6 cells/microL)	SI Units (10^{12} cells/L) (Conventional Units \times 1)
Cord blood	3.61–5.81	3.61–5.81
0–1 wk	4.51–7.01	4.51–7.01
2–3 wk	3.71–6.11	3.71–6.11

(table continues on page 504)

Age	Conventional Units (10^6 cells/microL)	SI Units (10^{12} cells/L) (Conventional Units \times 1)
1–2 mo	3.11–5.11	3.11–5.11
3–11 mo	3.01–5.01	3.01–5.01
1–5 yr	3.81–5.01	3.81–5.01
6–8 yr	3.91–5.11	3.91–5.11
9–14 yr	3.91–5.61	3.91–5.61
15 yr–adult		
Male	5.21–5.81	5.21–5.81
Female	3.91–5.11	3.91–5.11
Older adult		
Male	3.81–5.81	3.81–5.81
Female	3.71–5.31	3.71–5.31

DESCRIPTION: The red blood cell (RBC) count is a component of the CBC. It determines the number of RBCs per cubic millimeter of whole blood. The main role of RBCs, which contain the pigmented protein hemoglobin (Hgb), is the transport and exchange of oxygen to the tissues. Some carbon dioxide is returned from the tissues to the lungs by RBCs. RBC production in healthy adults takes place in the bone marrow of the vertebrae, pelvis, ribs, sternum, skull, and proximal ends of the femur and humerus. Production of RBCs is regulated by a hormone called erythropoietin which is produced and secreted by the kidneys. Normal RBC development and function are dependent on adequate levels of vitamin B₁₂, folic acid, vitamin E, and iron. The average life span of normal RBCs is 120 days. Old or damaged RBCs are removed from circulation by the spleen. The liver is responsible for the breakdown of hemoglobin and other cellular contents released from destroyed RBCs. *Polycythemia* is a condition resulting from an abnormal increase in Hgb, hematocrit (Hct), and RBC count. *Anemia* is a condition resulting from an abnormal

decrease in Hgb, Hct, and RBC count. Results of the Hgb, Hct, and RBC count should be evaluated simultaneously because the same underlying conditions affect this triad of tests similarly. The RBC count multiplied by 3 should approximate the Hgb concentration. The Hct should be within three times the Hgb if the RBC population is normal in size and shape. The Hct plus 6 should approximate the first two figures of the RBC count within 3 (e.g., Hct is 40%; therefore $40 + 6 = 46$, and the RBC count should be 4.6 or in the range 4.3 to 4.9). (See “Complete Blood Count, Hematocrit,” “Complete Blood Count, Hemoglobin,” and “Complete Blood Count, RBC Indices.”)

This procedure is contraindicated for: N/A

INDICATIONS

- Detect a hematological disorder involving RBC destruction (e.g., hemolytic anemia)
- Determine the presence of hereditary hematological abnormality

- Monitor the effects of acute or chronic blood loss
- Monitor the effects of physical or emotional stress on the patient
- Monitor patients with disorders associated with elevated erythrocyte counts (e.g., polycythemia vera, chronic obstructive pulmonary disease [COPD])
- Monitor the progression of non-hematological disorders associated with elevated erythrocyte counts, such as COPD, liver disease, hypothyroidism, adrenal dysfunction, bone marrow failure, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially upon admission to a health-care facility or before surgery

POTENTIAL DIAGNOSIS

Increased in

- Anxiety or stress (*related to physiological response*)
- Bone marrow failure (*initial response is stimulation of RBC production*)
- COPD with hypoxia and secondary polycythemia (*related to chronic hypoxia that stimulates production of RBCs and a corresponding increase in RBCs*)
- Dehydration with hemoconcentration (*related to decrease in total blood volume relative to unchanged RBC count*)
- Erythremic erythrocytosis (*related to unchanged total blood volume relative to increase in RBC count*)
- High altitude (*related to hypoxia that stimulates production of RBCs*)

- Polycythemia vera (*related to abnormal bone marrow response resulting in overproduction of RBCs*)

Decreased in

- Chemotherapy (*related to reduced RBC survival*)
- Chronic inflammatory diseases (*related to anemia of chronic disease*)
- Hemoglobinopathy (*related to reduced RBC survival*)
- Hemolytic anemia (*related to reduced RBC survival*)
- Hemorrhage (*related to overall decrease in RBC count*)
- Hodgkin's disease (*evidenced by bone marrow failure that results in decreased RBC production*)
- Leukemia (*evidenced by bone marrow failure that results in decreased RBC production*)
- Multiple myeloma (*evidenced by bone marrow failure that results in decreased RBC production*)
- Nutritional deficit (*related to deficiency of iron or vitamins required for RBC production and/or maturation*)
- Overhydration (*related to increase in blood volume relative to unchanged RBC count*)
- Pregnancy (*related to anemia; normal dilutional effect*)
- Renal disease (*related to decreased production of erythropoietin*)
- Subacute endocarditis

CRITICAL FINDINGS

The presence of abnormal cells, other morphological characteristics, or cellular inclusions may signify a potentially life-threatening or serious health condition and should be investigated. Examples are the presence of sickle cells, moderate numbers of spherocytes, marked schistocytosis, oval

macrocytes, basophilic stippling, nucleated RBCs (if the patient is not an infant), or malarial organisms.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Low RBC count leads to anemia. Anemia can be caused by blood loss, decreased blood cell production, increased blood cell destruction, or hemodilution. Causes of blood loss include menstrual excess or frequency, gastrointestinal bleeding, inflammatory bowel disease, or hematuria. Decreased blood cell production can be caused by folic acid deficiency, vitamin B₁₂ deficiency, iron deficiency, or chronic disease. Increased blood cell destruction can be caused by a hemolytic reaction, chemical reaction, medication reaction, or sickle cell disease. Hemodilution can be caused

by congestive heart failure, renal failure, polydipsia, or overhydration. Symptoms of anemia (due to these causes) include anxiety, dyspnea, edema, hypertension, hypotension, hypoxia, jugular venous distention, fatigue, pallor, rales, restlessness, and weakness. Treatment of anemia depends on the cause.

High RBC count leads to polycythemia. Polycythemia can be caused by dehydration, decreased oxygen levels in the body, and an overproduction of RBCs by the bone marrow. Dehydration by diuretic use, vomiting, diarrhea, excessive sweating, severe burns, or decreased fluid intake decreases the plasma component of whole blood, thereby increasing the ratio of RBCs to plasma, and leads to a higher than normal Hct. Causes of decreased oxygen include smoking, exposure to carbon monoxide, high altitude, and chronic lung disease, which leads to a mild hemoconcentration of blood in the body to carry more oxygen to the body's tissues. An overproduction of RBCs by the bone marrow leads to polycythemia vera, which is a rare chronic myeloproliferative disorder that leads to a severe hemoconcentration of blood. Severe hemoconcentration can lead to thrombosis (spontaneous blood clotting). Symptoms of hemoconcentration include decreased pulse pressure and volume, loss of skin turgor, dry mucous membranes, headaches, hepatomegaly, low central venous pressure, orthostatic hypotension, pruritus (especially after a hot bath), splenomegaly, tachycardia, thirst, tinnitus, vertigo, and weakness. Treatment of polycythemia depends on the cause. Possible interventions for hemoconcentration due to dehydration include intravenous fluids and discontinuance of diuretics if they are believed to be contributing to critically elevated Hct. Polycythemia due to decreased oxygen states can be treated by removal of the offending substance,

such as smoke or carbon monoxide. Treatment includes oxygen therapy in cases of smoke inhalation, carbon monoxide poisoning, and desaturating chronic lung disease. Symptoms of polycythemic overload crisis include signs of thrombosis, pain and redness in extremities, facial flushing, and irritability. Possible interventions for hemoconcentration due to polycythemia include therapeutic phlebotomy and intravenous fluids.

INTERFERING FACTORS

- Drugs and substances that may decrease RBC count by causing hemolysis resulting from drug sensitivity or enzyme deficiency include acetaminophen, aminopyrine, aminosalicic acid, amphetamine, anticonvulsants, antipyrene, arsenicals, benzene, busulfan, carbenicillin, cephalothin, chemotherapy drugs, chlorate, chloroquine, chlorothiazide, chlorpromazine, colchicine, diphenhydramine, dipyrone, glucosulfone, gold, hydroflumethiazide, indomethacin, mephenytoin, nalidixic acid, neomycin, nitrofurantoin, penicillin, phenacetamide, phenazopyridine, and phenothiazine.
- Drugs that may decrease RBC count by causing anemia include miconazole, penicillamine, phenylhydrazine, primaquine, probenecid, pyrazolones, pyrimethamine, quinines, streptomycin, sulfamethizole, sulfamethoxypyridazine, sulfisoxazole, suramin, thioridazine, tolbutamide, trimethadione, and tripelenamine.
- Drugs that may decrease RBC count by causing bone marrow suppression include amphotericin B, floxuridine, and phenylbutazone.
- Drugs and vitamins that may increase the RBC count include glucocorticosteroids, pilocarpine, and vitamin B₁₂.
- Use of the nutraceutical liver extract is strongly contraindicated in patients with iron-storage disorders such as hemochromatosis because it is rich in heme (the iron-containing pigment in Hgb).
- Hemodilution (e.g., excessive administration of intravenous fluids, normal pregnancy) in the presence of a normal number of RBCs may lead to false decreases in RBC count.
- Cold agglutinins may falsely increase the mean corpuscular volume (MCV) and decrease the RBC count. This can be corrected by warming the blood or diluting the sample with warmed saline and repeating the analysis.
- Excessive exercise, anxiety, pain, and dehydration may cause false elevations in RBC count.
- The results of a CBC should be carefully evaluated during transfusion or acute blood loss because the body is not in a state of homeostasis and values may be misleading. Considerations for draw times after transfusion include the type of product, the amount of product transfused, and the patient's clinical situation. Generally, specimens collected an hour after transfusion will provide an acceptable reflection of the effects of the transfused product. Measurements taken during a massive transfusion are an exception, providing essential guidance for therapeutic decisions during critical care.
- RBC counts can vary depending on the patient's position, decreasing when the patient is recumbent as a result of hemodilution and increasing when the patient rises as a result of hemoconcentration.
- Venous stasis can falsely elevate RBC counts; therefore, the tourniquet should not be left on the arm for longer than 60 sec.

- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens must be rejected for analysis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for anemia and disorders affecting the number of circulating RBCs.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, gastrointestinal, genitourinary, hematopoietic, hepatobiliary, immune, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 24 hr when stored at room temperature or within 48 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 24 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 24 hr will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic WBCs.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Nutritional therapy may be indicated for patients with decreased RBC count. Iron

deficiency is the most common nutrient deficiency in the United States. Patients at risk (e.g., children, pregnant women and women of childbearing age, low-income populations) should be instructed to include foods that are high in iron in their diet, such as meats (especially liver), eggs, grains, green leafy vegetables, and multivitamins with iron. Iron absorption is affected by numerous factors (see monograph titled "Iron").

▶ **Nutritional Considerations:** Patients at risk for vitamin B₁₂ or folate deficiency include those with the following conditions: malnourishment (inadequate intake), pregnancy (increased need), infancy, malabsorption syndromes (inadequate absorption/increased metabolic rate), infections, cancer, hyperthyroidism, serious burns, excessive blood loss, and gastrointestinal damage. Instruct the patient with vitamin B₁₂ deficiency, as appropriate, in the use of vitamin supplements. Inform the patient, as appropriate, that the best dietary sources of vitamin B₁₂ are meats, milk, cheese, eggs, and fortified soy milk products. Instruct the folate-deficient patient (especially pregnant women), as appropriate, to eat foods rich in folate, such as meats (especially liver), salmon, eggs, beets, asparagus, green leafy vegetables such as spinach, cabbage, oranges, broccoli, sweet potatoes, kidney beans, and whole wheat.

▶ **Nutritional Considerations:** A diet deficient in vitamin E puts the patient at risk for increased RBC destruction, which could lead to anemia. Nutritional therapy may be indicated for these patients. Educate the patient with a vitamin E deficiency, if appropriate, that the main dietary sources of vitamin E are vegetable oils including olive oil, whole grains, wheat germ, nuts, milk,

eggs, meats, fish, and green leafy vegetables. Vitamin E is fairly stable at most cooking temperatures (except frying) and when exposed to acidic foods. Supplemental vitamin E may also be taken, but the danger of toxicity should be explained to the patient. Very large supplemental doses, in excess of 600 mg of vitamin E over a period of 1 yr, may result in excess bleeding. Vitamin E is heat stable but is very negatively affected by light.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Educate the patient regarding access to nutritional counseling services. Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, biopsy kidney, blood groups and antibodies, CBC, CBC hematocrit, CBC hemoglobin, CBC RBC morphology and inclusions, Coombs' antiglobulin, erythropoietin, fecal analysis, ferritin, folate, gallium scan, haptoglobin, iron/TIBC, lymphangiogram, Meckel's diverticulum scan, reticulocyte count, and vitamin B₁₂.
- ▶ Refer to the Cardiovascular, Gastrointestinal, Genitourinary, Hematopoietic, Hepatobiliary, Immune, and Respiratory systems tables at the end of the book for related tests by body system.

Complete Blood Count, RBC Indices

SYNONYM/ACRONYM: Mean corpuscular hemoglobin (MCH), mean corpuscular volume (MCV), mean corpuscular hemoglobin concentration (MCHC), red blood cell distribution width (RDW).

COMMON USE: To evaluate cell size, shape, weight, and hemoglobin concentration. Used to diagnose and monitor therapy for diagnoses such as iron-deficiency anemia.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Automated, computerized, multichannel analyzers)

Age	MCV (fL)	MCH (pg/cell)	MCHC (g/dL)	RDWCV	RDWSD
Cord blood	107–119	35–39	31–35	14.9–18.7	51–66
0–1 wk	104–116	29–45	24–36	14.9–18.7	51–66
2–3 wk	95–117	26–38	26–34	14.9–18.7	51–66
1–2 mo	81–125	25–37	26–34	14.9–18.7	44–55
3–11 mo	78–110	22–34	26–34	14.9–18.7	35–46
1–5 yr	74–94	24–32	30–34	11.6–14.8	35–42
6–8 yr	73–93	24–32	32–36	11.6–14.8	35–42
9–14 yr	74–94	25–33	32–36	11.6–14.8	37–44
15 yr–adult					
Male	77–97	26–34	32–36	11.6–14.8	38–48
Female	78–98	26–34	32–36	11.6–14.8	38–48
Older adult					
Male	79–103	27–35	32–36	11.6–14.8	38–48
Female	78–102	27–35	32–36	11.6–14.8	38–48

MCV = mean corpuscular volume; MCH = mean corpuscular hemoglobin; MCHC = mean corpuscular hemoglobin concentration; RDWCV = coefficient of variation in red blood cell distribution width; RDWSD = standard deviation in RBC distribution width index.

DESCRIPTION: Red blood cell (RBC) indices provide information about RBC size and hemoglobin content. The indices are derived from mathematical relationships between the RBC count, Hgb level, and Hct. RBC indices are frequently used to assist in the classification of anemias. The mean corpuscular volume (MCV) reflects the average size

of circulating RBCs and classifies size as normocytic, microcytic (smaller than normal), and macrocytic (larger than normal). MCV is determined by dividing the Hct by the total RBC. The RDW is a measurement of cell size distribution. Many of the commonly used automated cell counters report the more sophisticated statistical indices, RDWCV and RDWCV

instead of RDW. The RDWCV is an indication of variation in cell size over the circulating RBC population. The RDWSD is also an indicator of variation in RBC size, is not affected by the MCV as with the RDWCV index, and is a more accurate measurement of the degree of variation in cell size. Review of peripheral smears is used to corroborate findings from automated instruments. Excessive variations in cell size are graded from 1+ to 4+, with 4+ indicating the most severe degree of anisocytosis, or variation in cell size. Mean corpuscular hemoglobin (MCH or average amount of Hgb in RBCs) and mean corpuscular hemoglobin concentration (MCHC or average amount of

Hgb per volume of RBCs) are used to measure hemoglobin content. Microscopic review of the peripheral smear can also be used to visually confirm automated values. Terms used to describe the hemoglobin content of RBCs are normochromic, hypochromic, and hyperchromic. The findings are also visually graded from 1+ to 4+. The MCH is determined by dividing the total hemoglobin by the RBC count. MCHC is determined by dividing total hemoglobin by hematocrit. (See “Complete Blood Count, Hemoglobin,” “Complete Blood Count, Hematocrit,” “Complete Blood Count, RBC Count,” and “Complete Blood Count, RBC Morphology and Inclusions.”)

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of anemia
- Detect a hematological disorder, neoplasm, or immunological abnormality
- Determine the presence of a hereditary hematological abnormality
- Monitor the effects of physical or emotional stress
- Monitor the progression of nonhematological disorders such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a complete blood count (CBC) in a general physical examination, especially upon admission to a health-care facility or before surgery

POTENTIAL DIAGNOSIS

Increased in

MCV

- Alcoholism (*vitamin deficiency related to malnutrition*)
- Antimetabolite therapy (*the therapy inhibits vitamin B₁₂ and folate*)
- Liver disease (*complex effect on RBCs that includes malnutrition, alterations in RBC shape and size, effects of chronic disease*)
- Pernicious anemia (vitamin B₁₂/folate anemia)

MCH

- Macrocytic anemias (*related to increased hemoglobin or cell size*)

MCHC

- Spherocytosis (*artifact in measurement caused by abnormal cell shape*)

RDW

- Anemias with heterogeneous cell size as a result of hemoglobinopathy, hemolytic anemia, anemia following acute blood loss, iron-deficiency anemia, vitamin- and folate-deficiency anemia (*related to a mixture of cell sizes as the bone marrow responds to the anemia and/or to a mixture of cell shapes due to cell fragmentation as a result of the disease*)

Decreased in**MCV**

- Iron-deficiency anemia (*related to low hemoglobin*)
- Thalassemias (*related to low hemoglobin*)

MCH

- Hypochromic anemias (*related to low hemoglobin*)
- Microcytic anemias (*related to low hemoglobin*)

MCHC

- Iron-deficiency anemia (*the amount of hemoglobin in the RBC is small relative to RBC size*)

RDW: N/A**CRITICAL FINDINGS:** N/A**INTERFERING FACTORS**

- Drugs and substances that may decrease the MCHC include styrene (occupational exposure).
- Drugs that may decrease the MCV include nitrofurantoin.
- Drugs that may increase the MCV include colchicine, pentamidine, pyrimethamine, and triamterene.
- Drugs that may increase the MCH and MCHC include oral contraceptives (long-term use).

- Diseases that cause agglutination of RBCs will alter test results.
- Cold agglutinins may falsely increase the MCV and decrease the RBC count. This can be corrected by warming the blood or diluting the sample with warmed saline and then correcting the RBC count mathematically.
- RBC counts can vary depending on the patient's position, decreasing when the patient is recumbent as a result of hemodilution and increasing when the patient rises as a result of hemoconcentration.
- The results of a CBC should be carefully evaluated during transfusion or acute blood loss because the body is not in a state of homeostasis and values may be misleading. Considerations for draw times after transfusion include the type of product, the amount of product transfused, and the patient's clinical situation. Generally, specimens collected an hour after transfusion will provide an acceptable reflection of the effects of the transfused product. Measurements taken during a massive transfusion are an exception, providing essential guidance for therapeutic decisions during critical care.
- Venous stasis can falsely elevate RBC counts; therefore, the tourniquet should not be left on the arm for longer than 60 sec.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens should be rejected.
- Lipemia will falsely increase the hemoglobin measurement, also affecting the MCV and MCH.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing RBC shape and size.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal, hematopoietic, immune, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 24 hr when stored at room temperature or within 48 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 24 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 24 hr may contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change

in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▶ Related tests include biopsy bone marrow, CBC, CBC hematocrit, CBC hemoglobin, CBC RBC count, CBC RBC morphology and inclusions,

CBC WBC count and differential, erythropoietin, ferritin, folate, Hgb electrophoresis, iron/TIBC, lead, reticulocyte count, sickle cell screen, and vitamin B₁₂.

▶ Refer to the Gastrointestinal, Hematopoietic, Immune, and Respiratory systems tables at the end of the book for related tests by body system.

Complete Blood Count, RBC Morphology and Inclusions

SYNONYM/ACRONYM: N/A.

COMMON USE: To make a visual evaluation of the red cell shape and/or size as a confirmation in assisting to diagnose and monitor disease progression.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube or Wright's-stained, thin-film peripheral blood smear. The laboratory should be consulted as to the necessity of thick-film smears for the evaluation of malarial inclusions.

NORMAL FINDINGS: (Method: Microscopic, manual review of stained blood smear)

Red Blood Cell Morphology	Within Normal Limits	1+	2+	3+	4+
<i>Size</i>					
Anisocytosis	0–5	5–10	10–20	20–50	Greater than 50

Intracellular parasites (e.g., <i>Plasmodium</i> , <i>Babesia</i> , <i>Trypanosoma</i>)	Absent	Reported as present or absent			

DESCRIPTION: The decision to manually review a peripheral blood smear for abnormalities in red blood cell (RBC) shape or size is made on the basis of criteria established by the reporting laboratory. Cues in the results of the complete blood count (CBC) will point to specific abnormalities that can be confirmed visually by microscopic review of the sample on a stained blood smear.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of anemia
- Detect a hematological disorder, neoplasm, or immunological abnormality
- Determine the presence of a hereditary hematological abnormality
- Monitor the effects of physical or emotional stress on the patient
- Monitor the progression of non-hematological disorders, such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy, and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially upon admission to a health-care facility or before surgery

POTENTIAL DIAGNOSIS

Red Blood Cell Size

Increased in

Cell Size

- Alcoholism
- Aplastic anemia

- Chemotherapy
- Chronic hemolytic anemia
- Grossly elevated glucose (hyperosmotic)
- Hemolytic disease of the newborn
- Hypothyroidism
- Leukemia
- Lymphoma
- Metastatic carcinoma
- Myelofibrosis
- Myeloma
- Refractory anemia
- Sideroblastic anemia
- Vitamin B₁₂/folate deficiency (*related to impaired DNA synthesis and delayed cell division, which permits the cells to grow for a longer period than normal*)

Decreased in

Cell Size

- Hemoglobin C disease
- Hemolytic anemias
- Hereditary spherocytosis
- Inflammation
- Iron-deficiency anemia
- Thalassemias

Red Blood Cell Shape

Variations in cell shape are the result of hereditary conditions such as elliptocytosis, sickle cell anemia, spherocytosis, thalassemias, or hemoglobinopathies (e.g., hemoglobin C disease). Irregularities in cell shape can also result from acquired conditions, such as physical/mechanical cellular trauma, exposure to chemicals, or reactions to medications.

- Acquired spherocytosis can result from Heinz body hemolytic anemia, microangiopathic hemolytic anemia, secondary isoimmunohemolytic anemia, and transfusion of old banked blood.
- Acanthocytes are associated with acquired conditions such as alcoholic cirrhosis with hemolytic

anemia, disorders of lipid metabolism, hepatitis of newborns, malabsorptive diseases, metastatic liver disease, the postsplenectomy period, and pyruvate kinase deficiency.

- Burr cells are commonly seen in acquired renal insufficiency, burns, cardiac valve disease, disseminated intravascular coagulation (DIC), hypertension, intravenous fibrin deposition, metastatic malignancy, normal neonatal period, and uremia.
- Codocytes are seen in hemoglobinopathies, iron-deficiency anemia, obstructive liver disease, and the postsplenectomy period.
- Dacryocytes are most commonly associated with metastases to the bone marrow, myelofibrosis, myeloid metaplasia, pernicious anemia, and tuberculosis.
- Schistocytes are seen in burns, cardiac valve disease, DIC, glomerulonephritis, hemolytic anemia, microangiopathic hemolytic anemia, renal graft rejection, thrombotic thrombocytopenic purpura, uremia, and vasculitis.

Red Blood Cell Hemoglobin Content

- RBCs with a normal hemoglobin (Hgb) level have a clear central pallor and are referred to as *normochromic*.
- Cells with low Hgb and lacking in central pallor are referred to as *hypochromic*. Hypochromia is associated with iron-deficiency anemia, thalassemias, and sideroblastic anemia.
- Cells with excessive Hgb levels are referred to as *hyperchromic* even though they technically lack a central pallor. Hyperchromia is usually associated with an elevated mean corpuscular Hgb concentration as well as hemolytic anemias.

- Cells referred to as *polychromic* are young erythrocytes that still contain ribonucleic acid (RNA). The RNA is picked up by the Wright's stain. Polychromasia is indicative of premature release of RBCs from bone marrow secondary to increased erythropoietin stimulation.

Red Blood Cell Inclusions

RBC inclusions can result from certain types of anemia, abnormal Hgb precipitation, or parasitic infection.

- Cabot rings may be seen in megaloblastic and other anemias, lead poisoning, and conditions in which RBCs are destroyed before they are released from bone marrow.
- Basophilic stippling is seen whenever there is altered Hgb synthesis, as in thalassemias, megaloblastic anemias, alcoholism, and lead or arsenic intoxication.
- Howell-Jolly bodies are seen in sickle cell anemia, other hemolytic anemias, megaloblastic anemia, congenital absence of the spleen, and the postsplenectomy period.
- Pappenheimer bodies may be seen in cases of sideroblastic anemia, thalassemias, refractory anemia, dyserythropoietic anemias, hemosiderosis, and hemochromatosis.
- Heinz bodies are most often seen in the blood of patients who have ingested drugs known to induce the formation of these inclusion bodies. They are also seen in patients with hereditary glucose-6-phosphate dehydrogenase (G6PD) deficiency.
- Hgb C crystals can often be identified in stained peripheral smears of patients with hereditary hemoglobin C disease.

- Parasites such as *Plasmodium* (transmitted by mosquitoes and causing malaria) and *Babesia* (transmitted by ticks), known to invade human RBCs, can be visualized with Wright's stain and other special stains of the peripheral blood.

CRITICAL FINDINGS

The presence of sickle cells or parasitic inclusions should be brought to the immediate attention of the requesting HCP.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Drugs and substances that may increase Heinz body formation as an initial precursor to significant hemolysis include acetanilid, acetylsalicylic acid, aminopyrine, antimalarials, antipyretics, furalta-done, furazolidone, methylene

blue, naphthalene, and nitrofurans.

- The results of a complete blood count (CBC) should be carefully evaluated during transfusion or acute blood loss because the body is not in a state of homeostasis and values may be misleading. Considerations for draw times after transfusion include the type of product, the amount of product transfused, and the patient's clinical situation. Generally, specimens collected an hour after transfusion will provide an acceptable reflection of the effects of the transfused product. Measurements taken during a massive transfusion are an exception, providing essential guidance for therapeutic decisions during critical care.
- Leaving the tourniquet in place for longer than 60 sec can falsely affect the results.
- Morphology can be evaluated to some extent via indices; therefore, failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be a reason for specimen rejection.
- Hemolyzed or clotted specimens should be rejected.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing red cell appearance.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's gastrointestinal, hematopoietic, hepatobiliary, immune, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. An EDTA Microtainer sample may be obtained from infants, children, and adults for whom venipuncture may not be feasible. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 6 hr when stored at

- room temperature or within 24 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 4 to 6 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 6 hr will contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and avoid the use of tobacco.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, CBC, CBC hematocrit, CBC hemoglobin, CBC platelet count, CBC RBC count, CBC

RBC indices, CBC WBC count with differential, δ -aminolevulinic acid, erythropoietin, ferritin, G6PD, hemoglobin electrophoresis, iron/TIBC, lead, and reticulocyte count.

Refer to the Gastrointestinal, Hematopoietic, Hepatobiliary, Immune, and Respiratory systems tables at the end of the book for related tests by body system.

C

Complete Blood Count, WBC Count and Differential

SYNONYM/ACRONYM: WBC with diff, leukocyte count, white cell count.

COMMON USE: To evaluate viral and bacterial infections and to assist in diagnosing and monitoring leukemic disorders.

SPECIMEN: Whole blood from one full lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Automated, computerized, multichannel analyzers. Many analyzers can determine a five- or six-part WBC differential. The six-part automated WBC differential identifies and enumerates neutrophils, lymphocytes, monocytes, eosinophils, basophils, and immature granulocytes (IG), where IG represents the combined enumeration of promyelocytes, metamyelocytes, and myelocytes as both an absolute number and a percentage. The five-part WBC differential includes all but the immature granulocyte parameters.)

White Blood Cell Count and Differential

Age	Conventional Units WBC \times $10^3/\mu\text{mL}$	Neutrophils (Absolute) and %	Lymphocytes (Absolute) and %	Monocytes (Absolute) and %	Eosinophils (Absolute) and %	Basophils (Absolute) and %
Birth	9.1–30.1	(5.5–18.3) 24–58%	(2.8–9.3) 26–56%	(0.5–1.7) 7–13%	(0.02–0.7) 0–8%	(0.1–0.2) 0–2.5%

White Blood Cell Count and Differential

Age	Immature Granulocytes (Absolute) ($10^3/\text{microL}$)	Immature Granulocyte Fraction (IGF) (%)
Birth–9 yr	0–0.03	0–0.4%
10 yr–older adult	0–0.09	0–0.9%

DESCRIPTION: White blood cells (WBCs) constitute the body's primary defense system against foreign organisms, tissues, and other substances. The life span of a normal WBC is 13 to 20 days. Old WBCs are destroyed by the lymphatic system and excreted in the feces. Reference values for WBC counts vary significantly with age. WBC counts vary diurnally, with counts being lowest in the morning and highest in the late afternoon. Other variables such as stress and high levels of activity or physical exercise can trigger transient increases of $2\text{--}5 \times 10^3/\text{microL}$. The main WBC types are neutrophils (band and segmented neutrophils), eosinophils, basophils, monocytes, and lymphocytes. WBCs are produced in the bone marrow. B-cell lymphocytes remain in the bone marrow to mature. T-cell lymphocytes migrate to and mature in the thymus. The WBC count can be performed alone with the differential cell count or as part of the complete blood count (CBC). The WBC differential can be performed by an automated instrument or manually on a slide prepared from a stained peripheral blood sample. Automated instruments provide excellent, reliable information, but the accuracy of the WBC count can be affected by the presence of circulating nucleated red blood cells (RBCs), clumped platelets, fibrin strands, cold agglutinins, cryoglobulins, intracellular parasitic organisms, or other significant

blood cell inclusions and may not be identified in the interpretation of an automated blood count. The decision to report a manual or automated differential is based on specific criteria established by the laboratory. The criteria are designed to identify findings that warrant further investigation or confirmation by manual review. An increased WBC count is termed *leukocytosis*, and a decreased WBC count is termed *leukopenia*. A total WBC count indicates the degree of response to a pathological process, but a more complete evaluation for specific diagnoses for any one disorder is provided by the differential count. The WBCs in the count and differential are reported as an *absolute value* and as a percentage. The relative percentages of cell types are arrived at by basing the enumeration of each cell type on a 100-cell count. The absolute value is obtained by multiplying the relative percentage value of each cell type by the total WBC count. For example, on a CBC report, with a total WBC of $9 \times 10^3/\text{microL}$ and WBC differential with 92% segmented neutrophils, 1% band neutrophils, 5% lymphocytes, and 1% monocytes the absolute values are calculated as follows: $92/100 \times 9 = 8.3$ segs, $1/100 \times 9 = 0.1$ bands, $5/100 \times 9 = 0.45$ lymphs, $1/100 \times 9 = 0.1$ monos for a total of 9.0 WBC count. The absolute neutrophil count (ANC) for this patient would be $9 \times (.92 + .1) = 8.4$.

The absolute neutrophil count (ANC) reflects the number of segmented and band type neutrophils in the total WBC count. It is used as an indicator of immune status because it reflects the type and number of WBC available to rapidly respond to an infection. Neutropenia is a decrease below normal in the number of neutrophils. $ANC = \text{Total WBC} \times ((\text{Segs}/100) + (\text{Bands}/100))$ or $\text{total WBC} \times (\% \text{ Segs} + \% \text{ Bands})$. The normal value varies with age but in general mild neutropenia is less than 1.5, moderate neutropenia is between 0.5 and 1, and severe neutropenia is less than 0.5. The ANC is helpful when managing patients receiving chemotherapy. It can drive decisions to place a hospitalized patient in isolation in order to protect them from exposure to infectious agents. When the patient is aware of their ANC they can also make informed decisions in taking actions to avoid exposure to crowds, avoid touching things in public places that may carry germs, or avoiding friends and family who may be sick.

Acute leukocytosis is initially accompanied by changes in the WBC count population, followed by changes within the individual WBCs. Leukocytosis usually occurs by way of increase in a single WBC family rather than a proportional increase in all cell types. Toxic granulation and vacuolation are commonly seen in leukocytosis accompanied by a *shift to the left*, or increase in the percentage of immature neutrophils to mature segmented neutrophils. An increased number or percentage of immature granulocytes, reflected by a shift to the left, represents production of WBCs and is useful as an indicator of infection. Immature neutrophils

are called bands and can represent 3–5% of total circulating neutrophils in healthy individuals. Bandemia is defined by the presence of greater than 6–10% band neutrophils in the total neutrophil cell population. These changes in the white cell population are most commonly associated with an infectious process, usually bacterial, but they can occur in healthy individuals who are under stress (in response to epinephrine production), such as women in childbirth and very young infants. The WBC count and differential of a woman in labor or of an actively crying infant may show an overall increase in WBCs with a shift to the left. Before initiating any kind of intervention, it is important to determine whether an increased WBC count is the result of a normal condition involving physiological stress or a pathological process. The use of multiple specimen types may confuse the interpretation of results in infants. Multiple samples from the same collection site (i.e., capillary versus venous) may be necessary to obtain an accurate assessment of the WBC picture in these young patients.

Neutrophils are normally found as the predominant WBC type in the circulating blood. Also called *polymorphonuclear cells*, they are the body's first line of defense through the process of phagocytosis. They also contain enzymes and pyogenes, which combat foreign invaders.

Lymphocytes are agranular, mononuclear blood cells that are smaller than granulocytes. They are found in the next highest percentage in normal circulation. Lymphocytes are classified as B cells and T cells. Both types are formed in the bone marrow, but

B cells mature in the bone marrow and T cells mature in the thymus. Lymphocytes play a major role in the body's natural defense system. B cells differentiate into immunoglobulin-synthesizing plasma cells. T cells function as cellular mediators of immunity and comprise helper/inducer (CD4) lymphocytes, delayed hypersensitivity lymphocytes, cytotoxic (CD8 or CD4) lymphocytes, and suppressor (CD8) lymphocytes.

Monocytes are mononuclear cells similar to lymphocytes, but they are related more closely to granulocytes in terms of their function. They are formed in the bone marrow from the same cells as those that produce neutrophils. The major function of monocytes is phagocytosis. Monocytes stay in the peripheral blood for about 70 hr, after which they migrate into the tissues and become macrophages.

The function of eosinophils is phagocytosis of antigen-antibody complexes. They become active in the later stages of inflammation. Eosinophils respond to allergic and parasitic diseases. They have granules that contain histamine used to kill foreign cells in the body and proteolytic enzymes that damage parasitic worms (see monograph titled "Eosinophil Count").

Basophils are found in small numbers in the circulating blood. They have a phagocytic function and, similar to eosinophils, contain numerous specific granules. Basophilic granules contain heparin, histamines, and serotonin. Basophils may also be found in tissue and as such are classified as mast cells. Basophilia is noted in conditions such as leukemia, Hodgkin's disease, polycythemia vera, ulcerative colitis, nephrosis, and chronic hypersensitivity states.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in confirming suspected bone marrow depression
- Assist in determining the cause of an elevated WBC count (e.g., infection, inflammatory process)
- Detect hematological disorder, neoplasm, or immunological abnormality
- Determine the presence of a hereditary hematological abnormality
- Monitor the effects of physical or emotional stress
- Monitor the progression of nonhematological disorders, such as chronic obstructive pulmonary disease, malabsorption syndromes, cancer, and renal disease
- Monitor the response to drugs or chemotherapy and evaluate undesired reactions to drugs that may cause blood dyscrasias
- Provide screening as part of a CBC in a general physical examination, especially on admission to a health-care facility or before surgery

POTENTIAL DIAGNOSIS

Increased in

Leukocytosis

- Normal physiological and environmental conditions:
 - Early infancy (*increases are believed to be related to the physiological stress of birth and metabolic demands of rapid development*)
 - Emotional stress (*related to secretion of epinephrine*)
 - Exposure to extreme heat or cold (*related to physiological stress*)
 - Pregnancy and labor (*WBC counts may be modestly elevated due to increased neutrophils into the third trimester and during labor, returning to normal within a week postpartum*)

Strenuous exercise (*related to epinephrine secretion; increases are short in duration, minutes to hours*)

Ultraviolet light (*related to physiological stress and possible inflammatory response*)

• Pathological conditions:

Acute hemolysis, especially due to splenectomy or transfusion reactions (*related to leukocyte response to remove lysed RBC fragments*)

All types of infections (*related to an inflammatory or infectious response*)

Anemias (*bone marrow disorders affecting RBC production may result in elevated WBC count*)

Appendicitis

Collagen disorders (*related to an inflammatory or infectious response*)

Cushing's disease (*related to overproduction of cortisol, a corticosteroid, which stimulates WBC production*)

Inflammatory disorders (*related to an inflammatory or infectious response*)

Leukemias and other malignancies (*related to bone marrow disorders that result in abnormal WBC production*)

Parasitic infestations (*related to an inflammatory or infectious response*)

Polycythemia vera (*myeloproliferative bone marrow disorder causing an increase in all cell lines*)

Decreased in

Leukopenia

- Normal physiological conditions
 - Diurnal rhythms (lowest in the morning)
- Pathological conditions
 - Alcoholism (*related to WBC changes associated with nutritional deficiencies of vitamin B₁₂ or folate*)
 - Anemias (*related to WBC changes associated with nutritional deficiencies of vitamin B₁₂ or folate, especially in megaloblastic anemias*)
 - Bone marrow depression (*related to decreased production*)
 - Malaria (*related to hypersplenism*)
 - Malnutrition (*related to WBC changes associated with nutritional deficiencies of vitamin B₁₂ or folate*)

Radiation (*related to physical cell destruction due to toxic effects of radiation*)

Rheumatoid arthritis (*related to side effect of medications used to treat the condition*)

Systemic lupus erythematosus (SLE) and other autoimmune disorders (*related to side effect of medications used to treat the condition*)

Toxic and antineoplastic drugs (*related to bone marrow suppression*)

Very low birth weight neonates (*related to bone marrow activity being diverted to develop RBCs in response to hypoxia*)

Viral infections (*leukopenia, lymphocytopenia, and abnormal lymphocytes may be present in the early stages of viral infections*)

Neutrophils Increased (neutrophilia)

- Acute hemolysis
- Acute hemorrhage
- Extremes in temperature
- Infectious diseases
- Inflammatory conditions (rheumatic fever, gout, rheumatoid arthritis, vasculitis, myositis)
- Malignancies
- Metabolic disorders (uremia, eclampsia, diabetic ketoacidosis, thyroid storm, Cushing's syndrome)
- Myelocytic leukemia
- Physiological stress (e.g., allergies, asthma, exercise, childbirth, surgery)
- Tissue necrosis (burns, crushing injuries, abscesses, myocardial infarction)
- Tissue poisoning with toxins and venoms

Neutrophils Decreased (neutropenia)

- Acromegaly
- Addison's disease
- Anaphylaxis
- Anorexia nervosa, starvation, malnutrition

- Bone marrow depression (viruses, toxic chemicals, overwhelming infection, radiation, Gaucher's disease)
- Disseminated SLE
- Thyrotoxicosis
- Viral infection (mononucleosis, hepatitis, influenza)
- Vitamin B₁₂ or folate deficiency

Lymphocytes Increased (lymphocytosis)

- Addison's disease
- Felty's syndrome
- Infections
- Lymphocytic leukemia
- Lymphomas
- Lymphosarcoma
- Myeloma
- Rickets
- Thyrotoxicosis
- Ulcerative colitis
- Waldenström's macroglobulinemia

Lymphocytes Decreased (lymphopenia)

- Antineoplastic drugs
- Aplastic anemia
- Bone marrow failure
- Burns
- Gaucher's disease
- Hemolytic disease of the newborn
- High doses of adrenocorticosteroids
- Hodgkin's disease
- Hypersplenism
- Immunodeficiency diseases
- Malnutrition
- Pernicious anemia
- Pneumonia
- Radiation
- Rheumatic fever
- Septicemia
- Thrombocytopenic purpura
- Toxic chemical exposure
- Transfusion reaction

Monocytes Increased (monocytosis)

- Carcinomas
- Cirrhosis
- Collagen diseases

- Gaucher's disease
- Hemolytic anemias
- Hodgkin's disease
- Infections
- Lymphomas
- Monocytic leukemia
- Polycythemia vera
- Radiation
- Sarcoidosis
- SLE
- Thrombocytopenic purpura
- Ulcerative colitis

CRITICAL FINDINGS

- Total WBC count of less than $2 \times 10^3/\text{microL}$ (SI: Less than $2 \times 10^9/\text{L}$)
- Absolute neutrophil count of less than $0.5 \times 10^3/\text{microL}$ (SI: Less than $0.5 \times 10^9/\text{L}$)
- Total WBC count of greater than $30 \times 10^3/\text{microL}$ (SI: Greater than $30 \times 10^9/\text{L}$)

Note and immediately report to the requesting health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any

orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

The presence of abnormal cells, other morphological characteristics, or cellular inclusions may signify a potentially life-threatening or serious health condition and should be investigated. Examples are hypersegmented neutrophils, agranular neutrophils, blasts or other immature cells, Auer rods, Döhle bodies, marked toxic granulation, or plasma cells.

INTERFERING FACTORS

- Drugs that may decrease the overall WBC count include acetyldigoxin, acetylsalicylic acid, aminoglutethimide, aminopyrine, aminosalicylic acid, ampicillin, amsacrine, antazoline, anticonvulsants, antineoplastic agents (therapeutic intent), antipyrene, barbiturates, busulfan, carbutamide, carmustine, chlorambucil, chloramphenicol, chlordane, chlorophenothane, chlortetracycline, chlorthalidone, cisplatin, colchicine, colistimethate, cycloheximide, cyclophosphamide, cytarabine, dacarbazine, dactinomycin, diaphragm, diazepam, diethylpropion, digitalis, dipyridamole, dipyrone, fumagillin, glaucarubin, glucosulfone, hexachlorobenzene, hydroflumethiazide, hydroxychloroquine, iothiouracil, iproniazid, lincomycin, local anesthetics, mafenamic acid, mepazine, meprobamate, mercaptopurine, methotrexate, methylpromazine, mitomycin, paramethadione, parathion, penicillin, phenacetamide, phenindione, phenothiazine, pipamazine, prednisone (by Coulter S method), primaquine, procainamide, procarbazine, prochlorperazine, promazine, promethazine, pyrazolones, quinacrine, quinines, radioactive compounds, razoxane, ristocetin, sulfa drugs, tamoxifen, tetracycline, thenalidine, thioridazine, tolazamide, tolazoline, tolbutamide, trimethadione, and urethane.
- A significant decrease in basophil count occurs rapidly after intravenous injection of propanidid and thiopental.
- A significant decrease in lymphocyte count occurs rapidly after administration of corticotropin, mechlorethamine, methysergide, and x-ray therapy; and after megadoses of niacin, pyridoxine, and thiamine.
- Drugs that may increase the overall WBC count include amphetamine, amphotericin B, chloramphenicol, chloroform (normal response to anesthesia), colchicine (leukocytosis follows leukopenia), corticotropin, erythromycin, ether (normal response to anesthesia), fluroxene (normal response to anesthesia), isoflurane (normal response to anesthesia), niacinamide, phenylbutazone, prednisone, and quinine.
- Drug allergies may have a significant effect on eosinophil count and may affect the overall WBC count. Refer to the monograph titled "Eosinophil Count" for a detailed listing of interfering drugs.
- The WBC count may vary depending on the patient's position, decreasing when the patient is recumbent owing to hemodilution and increasing when the patient rises owing to hemoconcentration.
- Venous stasis can falsely elevate results; the tourniquet should not be left on the arm for longer than 60 sec.
- Failure to fill the tube sufficiently (i.e., tube less than three-quarters full) may yield inadequate sample volume for automated analyzers and may be reason for specimen rejection.

- Hemolyzed or clotted specimens should be rejected for analysis.
- The presence of nucleated red blood cells or giant or clumped platelets affects the automated WBC, requiring a manual correction of the WBC count.
- Care should be taken in evaluating the CBC during the first few hours after transfusion.
- Patients with cold agglutinins or monoclonal gammopathies may have a falsely decreased WBC count as a result of cell clumping.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to metabolic or endocrine dysfunction; chronic debilitating illness; cirrhosis; trauma; vectors; decreased tissue perfusion; presence of gram—positive or gram-negative organisms</i>)	Temperature; increased heart rate; increased blood pressure; shaking; chills; mottled skin; lethargy; fatigue; swelling; edema; pain; localized pressure; diaphoresis; night sweats; confusion; vomiting; nausea; headache	Promote good hygiene; assist with hygiene as needed; administer prescribed antibiotics, antipyretics; provide cooling measures; administer prescribed IV fluids; monitor vital signs and trend temperatures; encourage oral fluids; adhere to standard or universal precautions; isolate as appropriate; obtain cultures as ordered; encourage use of lightweight clothing and bedding; monitor and trend indicators of infection (WBC, C-reactive protein [CRP])
Fluid volume (<i>Related to metabolic imbalances associated with disease process; insensible fluid loss; excessive diaphoresis</i>)	Deficient: decreased urinary output, fatigue, sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status	Record daily weight and monitor trends; record accurate intake and output; collaborate with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit); manage underlying cause of fluid alteration; monitor urine characteristics and

Problem	Signs & Symptoms	Interventions
Fever (<i>Related to increased basal metabolic rate; infection</i>)	Elevated temperature; flushed, warm skin; diaphoresis; skin warm to touch; tachycardia; tachypnea; seizures; convulsions	respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and intravenous fluids to provide optimal hydration status; administer replacement electrolytes as ordered Assess the patient's temperature frequently; monitor for emotional labile events that could precipitate a thyroid storm or crisis and precipitate an elevation in temperature; ensure the patient's immediate environment remains cool; encourage the use of light bedding and lightweight clothing to prevent overheating; increase fluid intake to offset insensible fluid loss; encourage bathing with tepid water for comfort and promotion of cooling; administer prescribed antithyroid therapy
Health management (<i>Related to failure to regulate diet; lack of exercise; alcohol use; smoking; complexity of health-care system; complexity of therapeutic management; altered metabolic process; knowledge deficit; conflicted decision making; cultural family health</i>)	Inability or failure to recognize or process information toward improving health and preventing illness with associated mental and physical effects; ineffective health choices; increasing symptoms of illness; verbalizes that therapeutic regime is too difficult; patient and family do not support HCP's suggestions for health improvement; refusal to follow recommended therapeutic regime	Ensure regular participation in weight-bearing exercise; assess diet, smoking, and alcohol use; teach the importance of adequate calcium intake with diet and supplements; refer to smoking cessation and alcohol treatment programs; teach the signs and symptoms of infection; assess family or cultural factors that impact the success of the therapeutic regime; assess the patient's self-assessment of his or her health status; include the patient and family in designing the plan of care; tailor the plan of care to the patient's lifestyle; collaborate with the patient and family to

(table continues on page 530)

Problem	Signs & Symptoms	Interventions
<p><i>patterns;</i> <i>barriers to</i> <i>healthy</i> <i>decisions;</i> <i>mistrust of</i> <i>health-care</i> <i>provider [HCP]</i></p>		<p>develop a system of managing own health; focus on behaviors that will make the biggest positive impact on improved health</p>

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for infection or monitoring leukemia.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic, immune, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. The specimen should be mixed gently by inverting the tube 10 times. The specimen should be analyzed within 24 hr when stored at room temperature or within 48 hr if stored at refrigerated temperature. If it is anticipated the specimen will not be analyzed within 24 hr, two blood smears should be made immediately after the venipuncture and submitted with the blood sample. Smears made from specimens older than 24 hr may contain an unacceptable number of misleading artifactual abnormalities of the RBCs, such as echinocytes and spherocytes, as well as necrobiotic white blood cells.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting HCP, who will discuss the results with the patient.

▶ **Nutritional Considerations:** Infection, fever, sepsis, and trauma can result in an impaired nutritional status. Malnutrition can occur for many reasons, including fatigue, lack of appetite, and gastrointestinal distress.

▶ **Nutritional Considerations:** Adequate intake of vitamins A and C, and zinc are also important for regenerating body stores depleted by the effort exerted in fighting infections. Educate the patient or caregiver regarding the importance of following the prescribed diet.

▶ **Nutritional Considerations:** Educate the patient with vitamin A deficiency, as appropriate, that the main dietary source of vitamin A comes from carotene, a yellow pigment noticeable in most fruits and vegetables, especially carrots, sweet potatoes, squash, apricots, and cantaloupe. It is also present in spinach, collards, broccoli, and cabbage. This vitamin is fairly stable at most cooking temperatures, but it is destroyed easily by light and oxidation.

Vitamin C

▶ **Nutritional Considerations:** Educate the patient with vitamin C deficiency, as appropriate, that citrus fruits are excellent dietary sources of vitamin C. Other good sources are green and red peppers, tomatoes, white potatoes, cabbage, broccoli, chard, kale, turnip greens, asparagus, berries, melons, pineapple, and guava.

Vitamin C is destroyed by exposure to air, light, heat, or alkalis. Boiling water before cooking eliminates dissolved oxygen that destroys vitamin C in the process of boiling. Vegetables should be crisp and cooked as quickly as possible.

▶ **Nutritional Considerations:** Topical or oral supplementation may be ordered for patients with zinc deficiency. Dietary sources high in zinc include shellfish, red meat, wheat germ, nuts, and processed foods such as canned pork and beans and canned chili. Patients should be informed that phytates (from

whole grains, coffee, cocoa, or tea) bind zinc and prevent it from being absorbed. Decreases in zinc also can be induced by increased intake of iron, copper, or manganese. Vitamin and mineral supplements with a greater than 3:1 iron/zinc ratio inhibit zinc absorption.

- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services.
- ▶ Provide contact information, if desired, for the National Cancer Institute (www.nci.nih.org) and for the Institute of Medicine of the National Academies (www.iom.edu).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding of the signs and symptoms of infection
- ▶ States understanding of the importance of compliance with follow-up laboratory tests to manage disease process

Skills

- ▶ Demonstrates proficiency in taking prescribed antibiotics
- ▶ Demonstrates proficiency in taking and recording temperature

Attitude

- ▶ Complies with the request to make lifestyle alterations that will decrease infection risk
- ▶ Complies with the request to increase fluid intake to offset fluid loss and prevent dehydration

RELATED MONOGRAPHS:

- ▶ Related tests include albumin, antibody, anti-neutrophilic cytoplasmic biopsy bone marrow, biopsy lymph node, CBC, CBC RBC

count, CBC RBC indices, CBC RBC morphology, culture bacterial (see individually listed culture monographs), culture fungal, culture viral, eosinophil count, ESR, fecal analysis, Gram stain, infectious mononucleosis, LAP, procalcitonin, UA, US abdomen, and WBC scan.

- ▶ Refer to the Hematopoietic, Immune, and Respiratory systems tables at the end of the book for related tests by body system.

Computed Tomography, Abdomen

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), abdominal CT, helical/spiral CT.

COMMON USE: To visualize and assess abdominal structures and to assist in diagnosing tumors, bleeding, and abscess. Used as an evaluation tool for surgical, radiation, and medical therapeutic interventions.

AREA OF APPLICATION: Abdomen.

CONTRAST: With or without oral or IV iodinated contrast medium.

DESCRIPTION: Abdominal computed tomography (CT) is a noninvasive procedure used to enhance certain anatomic views of the abdominal structures. It becomes invasive when contrast medium is used. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner

in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities,

and produces high-quality images. Differences in tissue density are detected and recorded and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the liver, biliary tract, pancreas, kidneys, spleen, intestines, and vascular system are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure may be repeated after intravenous injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for evaluation of bowel and adjacent structures. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. The CT scan can be used to guide biopsy needles into areas of abdominal tumors to obtain tissue for laboratory analysis and to guide placement of catheters for drainage of intra-abdominal abscesses. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients who are claustrophobic.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a

known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative non-contrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) ***because iodinated contrast is nephrotoxic.***
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, ***because of their risk of contrast-induced renal failure.***
- ◆ Patients with pheochromocytoma, ***because iodinated contrast may cause a hypertensive crisis.***
- ◆ Patients with bleeding disorders or receiving anticoagulant therapy ***because the puncture site may not stop bleeding.***

INDICATIONS

- Assist in differentiating between benign and malignant tumors
- Detect aortic aneurysms
- Detect tumor extension of masses and metastasis into the abdominal area

- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate between infectious and inflammatory processes
- Evaluate cysts, masses, abscesses, renal calculi, gastrointestinal (GI) bleeding and obstruction, and trauma
- Evaluate retroperitoneal lymph nodes
- Monitor and evaluate the effectiveness of medical, radiation, or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of abdominal organs and vascular system

Abnormal findings in

- Abdominal abscess
- Abdominal aortic aneurysm
- Adrenal tumor or hyperplasia
- Appendicitis
- Bowel obstruction
- Bowel perforation
- Dilatation of the common hepatic duct, common bile duct, or gallbladder
- GI bleeding
- Hematomas, diverticulitis, gallstones
- Hemoperitoneum
- Hepatic cysts or abscesses
- Pancreatic pseudocyst
- Primary and metastatic neoplasms
- Renal calculi
- Splenic laceration, tumor, infiltration, and trauma

CRITICAL FINDINGS

- Abscess
- Acute GI bleed
- Aortic aneurysm
- Appendicitis
- Aortic dissection
- Bowel perforation
- Bowel obstruction
- Mesenteric torsion
- Tumor with significant mass effect

- Visceral injury; significant solid organ laceration

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and cause unclear images.
- Patients with extreme claustrophobia unless sedation is given before the study.

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging Information on the Image Gently Campaign** can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast medium.
- ▶ Obtain a history of the patient's gastrointestinal and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.

- ▶ Review the procedure with the patient. Explain the purpose of the test and how the procedure is performed. Address concerns about pain and explain that there may be moments of

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the abdominal organs.

discomfort and some pain experienced during the test. Inform the patient that the procedure is performed in a radiology suite, usually by an HCP, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium, if given.
- ▶ The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) or a water-soluble oral contrast beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or

infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site.**

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluids, and medication restrictions for 8 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of contrast, emergency drugs, and sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table.
- ▶ If IV contrast media is used, during and after injection a rapid series of images is taken.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while

the x-ray images are taken, and then to exhale after the images are taken.

- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary from facility to facility.
- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.

- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH and challenge tests, amylase, angiography abdomen, biopsy intestinal, BUN, calculus kidney stone panel, CBC, CBC hematocrit, CBC hemoglobin, cortisol and challenge tests, creatinine, cystoscopy, hepatobiliary scan, IVP, KUB studies, MRI abdomen, peritoneal fluid analysis, PT/INR, renogram, US abdomen, and US pelvis.
- ▶ Refer to the Gastrointestinal and Hepatobiliary systems tables at the end of the book for related tests by body system.

Computed Tomography, Angiography

SYNONYM/ACRONYM: Computed axial tomography (CAT) angiography, CTA.

COMMON USE: To visualize and assess the vascular structure to assist in the diagnosis of aneurysm, embolism, or stenosis.

AREA OF APPLICATION: Vessels.

CONTRAST: IV iodinated contrast medium.

DESCRIPTION: Computed tomography angiography (CTA) is a noninvasive procedure that enhances certain anatomic views of vascular structures. It becomes invasive when contrast medium is used. This procedure complements traditional angiography and allows reconstruction of the images in different planes and removal of surrounding structures, leaving only the vessels to be studied. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities,

and produces high-quality images. Differences in tissue density are detected and recorded and are viewable as computerized digital images. These images are helpful when there are heavily calcified vessels. The axial images give the most precise information regarding the true extent of stenosis, and they can also evaluate intracerebral aneurysms. Small ulcerations and plaque irregularity are readily seen with CTA; the degree of stenosis can be estimated better with CTA because of the increased number of imaging planes. Density measurements are sent to a computer that produces a digital image of the anatomy, enabling the health-care provider (HCP) to look at slices or thin sections of certain anatomic views of the vessels. Iodinated contrast medium is given IV for vascular evaluation. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation

far outweigh the risk of radiation exposure to the fetus and mother.

- ◆ Patients who are claustrophobic.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
- ◆ Patients with pheochromocytoma, **because iodinated contrast may cause a hypertensive crisis.**

- ◆ Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Detect aneurysms
- Detect embolism or other occlusions
- Detect fistula
- Detect stenosis
- Detect peripheral artery disease (PAD)
- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate between vascular and nonvascular tumors
- Evaluate atherosclerosis
- Evaluate hemorrhage or trauma
- Monitor and evaluate the effectiveness of medical or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of vascular structures

Abnormal findings in

- Aortic aneurysm
- Cysts or abscesses
- Emboli
- Hemorrhage
- Neoplasm
- Occlusion
- PAD
- Shunting
- Stenosis

CRITICAL FINDINGS

- Brain or spinal cord ischemia
- Emboli
- Hemorrhage
- Leaking aortic aneurysm
- Occlusion
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the

requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Patients who are unable to cooperate or remain still during the

procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with the HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the cardiovascular system.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially

allergies or sensitivities to latex, anesthetics, or contrast mediums.

- ▶ Obtain a history of patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, important

in providing psychological support before, during, and after the procedure.

- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ Inform the patient that a burning and flushing sensation may be felt throughout the body during injection of the contrast medium. After injection of the contrast medium, the patient may experience an urge to cough, flushing, nausea, or a salty or metallic taste.
- ▶ Instruct the patient to remove all external metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or

drug. Use nonionic contrast medium for the procedure.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Establish an IV fluid line for the injection of contrast, emergency drugs, and sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table.
- ▶ The contrast medium is injected, and a rapid series of images is taken during and after the filling of the vessels to be examined. Delayed images may be taken to examine the vessels after a time and to monitor the venous phase of the procedure.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Observe that the needle is removed and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient to resume pretest-diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods. Renal function should be assessed before metformin is resumed.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Assess extremities for signs of ischemia or absence of distal pulse caused by a catheter-induced thrombus.
- ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- ▶ Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approach to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

- Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as

appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography of the specific area (abdomen, adrenal, carotid, coronary, pulmonary, renal), blood pool imaging, BUN, chest x-ray, colonoscopy, CBC, CBC hematocrit, CBC hemoglobin, CT of the specific area (abdomen, biliary/liver, brain, pituitary, renal, spine, spleen, thoracic), creatinine echocardiography, echocardiography transesophageal, fluorescein angiography, fundus photography, MRA, MRI of the specific area (abdomen, brain, chest, pituitary), MRI venography, MI scan, plethysmography, PET (brain, heart), proctosigmoidoscopy, PT/INR, US carotid, and US venous Doppler extremity.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Computed Tomography, Biliary Tract and Liver

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), abdominal CT, helical/spiral CT.

COMMON USE: To visualize and assess the structure of the liver and biliary tract toward the diagnosis of tumor, obstruction, bleeding, and infection. Used as an evaluation tool for surgical, radiation, and medical therapeutic interventions.

AREA OF APPLICATION: Liver, biliary tract, and adjacent structures.

CONTRAST: With or without IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) of the liver and biliary tract is a noninvasive procedure that enhances certain anatomic views of these structures. It becomes invasive with the use of contrast medium. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images. Differences in tissue density are detected and recorded and are viewable as

computerized digital images. Slices or thin sections of certain anatomic views of the liver, biliary tract, and adjacent structures are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions. The procedure may be repeated after IV injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for evaluation of bowel and adjacent structures. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. The CT scan can be used to guide biopsy needles into areas of liver and biliary tract masses to obtain tissue for laboratory analysis and for placement of needles to aspirate cysts or abscesses. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation

far outweigh the risk of radiation exposure to the fetus and mother.

-  Patients who are claustrophobic.
-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).
Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the non-iodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
-  Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
-  Patients with pheochromocytoma, **because iodinated**

contrast may cause a hypertensive crisis.

-  Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Assist in differentiating between benign and malignant tumors
- Detect dilation or obstruction of the biliary ducts with or without calcification or gallstone
- Detect liver abnormalities, such as cirrhosis with ascites and fatty liver
- Detect tumor extension of masses and metastasis into the hepatic area
- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate between obstructive and nonobstructive jaundice
- Differentiate infectious from inflammatory processes
- Evaluate hepatic cysts, masses, abscesses, and hematomas, or hepatic trauma
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and contour of the liver and biliary ducts

Abnormal findings in

- Dilation of the common hepatic duct, common bile duct, or gallbladder
- Gallstones
- Hematomas
- Hepatic cysts or abscesses
- Jaundice (obstructive or non-obstructive)
- Primary and metastatic neoplasms

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Patients who are unable to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from

frequent x-ray procedures.

Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the liver, biliary tract, and surrounding structures.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast medium.
- ▶ Obtain a history of the patient's hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.

- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium, if given.
- ▶ The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) or water soluble contrast beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.
- ▶ Instruct the patient to remove all external metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations for 8 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.

- ▶ Establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table.
- ▶ If IV contrast medium is used, a rapid series of images is taken during and after injection.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea,

hypertension, palpitations, nausea, or vomiting.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast media.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, AST, bilirubin, biopsy liver, BUN, CBC, CBC hematocrit, CBC hemoglobin, creatinine, GGT, hepatobiliary scan, KUB, liver and spleen scan, MRI abdomen, PT/INR, and US liver.
- ▶ Refer to the Hepatobiliary System table at the end of the book for related tests by body system.

Computed Tomography, Brain

SYNONYM/ACRONYM: Computed axial tomography (CAT) of the head, computed transaxial tomography (CTT) of the head, brain CT, helical/spiral CT.

COMMON USE: To visualize and assess the brain to assist in diagnosing tumor, bleeding, infarct, infection, structural changes, and edema. Also valuable in evaluation of medical, radiation, and surgical interventions.

AREA OF APPLICATION: Brain.

CONTRAST: With or without IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) of the brain is a noninvasive procedure used to assist in diagnosing abnormalities of the head, brain tissue, cerebrospinal fluid, and blood circulation. It becomes invasive if contrast medium is used. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images. Differences in

tissue density are detected and recorded and are viewable as computerized digital images.

Slices or thin sections of certain anatomic views of the brain and associated vascular system are viewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected aneurysms, intracranial bleeds, and subdural or epidural hematomas. The procedure may be repeated after intravenous injection of iodinated contrast medium for vascular evaluation. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning. Xenon-enhanced CT scanning is an imaging method used to assess cerebral blood flow. Xenon-133 is an odorless, colorless, radioactive gas that can either be inhaled or injected. The isotope moves rapidly through the blood into the brain. The diffused gas demonstrates how much blood goes to each area of the brain. Sensitivity of stroke detection in the acute phase is increased by using Xenon.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients who are claustrophobic.
-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).
Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) ***because iodinated contrast is nephrotoxic.***
-  Elderly and compromised patients who are chronically dehydrated before the test, ***because***

of their risk of contrast-induced renal failure.

-  Patients with pheochromocytoma, ***because iodinated contrast may cause a hypertensive crisis.***
-  Patients with bleeding disorders or receiving anticoagulant therapy ***because the puncture site may not stop bleeding.***

INDICATIONS

- Detect brain infection, abscess, or necrosis, as evidenced by decreased density on the image
- Detect ventricular enlargement or displacement by increased cerebrospinal fluid
- Determine benign and cancerous intracranial tumors and cyst formation, as evidenced by changes in tissue densities
- Determine cause of increased intracranial pressure
- Determine presence and type of hemorrhage in infants and children experiencing signs and symptoms of intracranial trauma or congenital conditions such as hydrocephalus and arteriovenous malformations (AVMs)
- Determine presence of multiple sclerosis, as evidenced by sclerotic plaques
- Determine lesion size and location causing infarct or hemorrhage
- Differentiate hematoma location after trauma (e.g., subdural, epidural, cerebral) and determine extent of edema, as evidenced by higher blood densities
- Differentiate between cerebral infarction and hemorrhage
- Evaluate abnormalities of the middle ear ossicles, auditory nerve, and optic nerve
- Monitor and evaluate the effectiveness of medical, radiation, or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of intracranial structures and vascular system

Abnormal findings in

- Abscess
- Alzheimer's disease
- Aneurysm
- AVMs
- Cerebral atrophy
- Cerebral edema
- Cerebral infarction
- Congenital abnormalities
- Craniopharyngioma
- Cysts
- Hematomas (e.g., epidural, subdural, intracerebral)
- Hemorrhage
- Hydrocephaly
- Increased intracranial pressure or trauma
- Infection
- Sclerotic plaques suggesting multiple sclerosis
- Tumor
- Ventricular or tissue displacement or enlargement

CRITICAL FINDINGS

- Abscess
- Acute hemorrhage
- Aneurysm
- Infarction
- Infection
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should

be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, dentures, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Patient who are unable to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with the HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who

are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the brain.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast medium.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that

barium studies were performed more than 4 days before the CT scan.

- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 15 to 30 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), contrast medium, dye, or sedatives.
- ▶ Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.
- ▶ Instruct the patient to remove dentures and jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food or fluid restrictions unless by medical direction. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the

procedure. Protocols may vary among facilities.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with medication restrictions and pretesting preparations.
- ▶ Ensure the patient has removed dentures and all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.

- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume medications and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.

- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography carotid, audiometry hearing loss, BUN, CSF analysis, CBC, CBC hematocrit, CBC hemoglobin, CT angiography, creatinine, EEG, EMG, evoked brain potentials, MR angiography, MRI brain, nerve fiber analysis, otoscopy, PET brain, PT/INR, spondee speech reception threshold, and tuning fork tests.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Computed Tomography, Cardiac Scoring

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), heart vessel calcium CT, helical/spiral CT, cardiac plaque CT.

COMMON USE: To visualize and assess coronary artery status related to plaque buildup, associated with coronary artery disease and heart failure. Used as an evaluation tool for surgical, radiation, and medical therapeutic interventions.

AREA OF APPLICATION: Heart.

CONTRAST: None.

DESCRIPTION: Cardiac scoring computed tomography (CT) is a noninvasive procedure used to enhance certain anatomic views of the heart for quantifying coronary artery calcium content. Coronary artery disease (CAD) occurs when the arteries that carry blood and oxygen to the heart muscle become clogged or built up with plaque. Plaque buildup slows the

flow of blood to the heart muscle, causing ischemia and increasing the risk of heart failure. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of

the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images. Cardiac scoring is a noninvasive test. Differences in plaque density are detected and recorded and are viewable as computerized digital images. The scanner takes an image of the beating heart while the patient holds his or her breath for approximately 20 sec. The procedure requires no contrast medium injections. These density measurements are sent to a computer that produces a digital analysis of the anatomy, enabling the health-care provider (HCP) to look at the quantified amount of calcium (cardiac plaque score) in the coronary arteries. The data can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. The Agatston score is the most frequently used scale to quantitate the amount of calcium in atherosclerotic plaque. Higher scores, greater than 100, are associated with a higher risk of death from cardiac causes.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a

procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

- ◆ Patients who are claustrophobic.

INDICATIONS

- Detect and quantify coronary artery calcium content
CAD is the leading cause of death in most industrialized nations. Cardiac scoring is a more powerful predictor of CAD than cholesterol screening. Of all myocardial infarctions (MIs), 45% occur in people younger than age 65. Of women who have had MIs, 44% will die within 1 yr after the attack. Women are more likely to die of heart disease than of breast cancer.
- Family history of heart disease
- Screening for coronary artery calcium in patients with:
Diabetes
High blood pressure
High cholesterol
High-stress lifestyle
Overweight by 20% or more
Personal history of smoking
Sedentary lifestyle
- Screening for coronary artery plaque in patients with chest pain of unknown cause

POTENTIAL DIAGNOSIS

Normal findings in

- If the score is 100 or less, the probability of having significant CAD is minimal or is unlikely to be causing a narrowing at the time of the examination.

Abnormal findings in

- If the score is between 100 and 400, a significant amount of calcified plaque was found in the coronary arteries. There is an increased risk of a future MI, and a medical assessment of cardiac risk factors needs to be done. Additional testing may be needed.

- If the score is greater than 400, the procedure has detected extensive calcified plaque in the coronary arteries, which may have caused a critical narrowing of the vessels. A full medical assessment is needed as soon as possible. Further testing may be needed, and treatment may be needed to reduce the risk of MI.

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Retained barium or radiological contrast from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Consultation with the HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging**

Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the coronary arteries for the presence of plaque.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.

Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, or sedatives.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction. Protocols may vary among facilities.
- ▶ Instruct the patient to remove all external metallic objects from the area to be examined.

INTRATEST:

Potential Complications:

Establishing an IV line is an invasive procedure. Complications are rare but do include risk for hematoma **related to blood leakage into the tissue following insertion of the IV needle** or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with pretesting preparations.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of emergency drugs and sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table. A rapid series of images is taken of the vessels to be examined.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ The IV needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ Instruct the patient in the care and assessment of the IV site.
- ▶ Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with

cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approach to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▸ **Social and Cultural Considerations:**

Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional

consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.

- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, BUN, calcium, chest x-ray, cholesterol (total, HDL, LDL), CRP, CBC, CBC hematocrit, CBC hemoglobin, coronary angiography, CT thorax, CK and isoenzymes, creatinine echocardiography, echocardiography transesophageal ECG, glucose, glycyated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, lung scan, magnesium, MRI chest, MI scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, PT/INR, triglycerides, and troponin.
- Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Computed Tomography, Colonoscopy

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), CT colonography, CT virtual colonoscopy.

COMMON USE: To visualize and assess the rectum and colon related to identification and evaluation of large polyps, lesions, and tumors. Also used to assess the effectiveness of therapeutic interventions such as surgery and primarily used for patients who cannot tolerate conventional colonoscopy.

AREA OF APPLICATION: Colon.

CONTRAST: Screening examinations are done without IV iodinated contrast medium. Examinations done to clarify questionable or abnormal areas may require IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) colonoscopy is a noninvasive technique that involves examining the colon by taking multiple CT scans of the patient's colon and rectum and using computer software to create three-dimensional images. It becomes invasive when contrast medium is used. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period

of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images. Differences in tissue density are detected and recorded and are viewable as computerized digital images. The procedure is used to detect polyps, which are growths of tissue in the colon or rectum. Some types of polyps increase the risk of colon cancer, especially if they are large or if a patient has several polyps. Compared to conventional colonoscopy, CT colonoscopy is less effective in detecting polyps smaller than 5 mm, more effective when the polyps are between 5 and 9.9 mm, and most effective when the polyps are 10 mm or larger. This test may be valuable for patients who have diseases rendering them unable to undergo conventional colonoscopy (e.g., bleeding disorders, lung or heart disease) and for patients who are unable to undergo the sedation required for traditional colonoscopy. The procedure is less invasive than conventional colonoscopy, with little risk of complications and no recovery

time. CT colonoscopy can be done as an outpatient procedure, and the patient may return to work or usual activities the same day. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

CT colonoscopy and conventional colonoscopy require the bowel to be cleansed before the examination. The screening procedure requires no contrast medium injections, but if a suspicious area or abnormality is detected, a repeat series of images may be completed after IV contrast medium is given. These density measurements are sent to a computer that produces a digital analysis of the anatomy, enabling a health-care provider (HCP) to look at slices or thin sections of certain anatomic views of the colon and vascular system. A drawback of CT colonoscopy is that polyp removal and biopsies of tissue in the colon must be done using conventional colonoscopy. Therefore, if polyps are discovered during CT colonoscopy and biopsy becomes necessary, the patient must undergo bowel preparation a second time.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients who are claustrophobic.
-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known

allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
-  Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
-  Patients with pheochromocytoma, **because iodinated contrast may cause a hypertensive crisis.**
-  Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Detect polyps in the colon
- Evaluate the colon for metachronous lesions

- Evaluate the colon in patients with obstructing rectosigmoid disease
- Evaluate polyposis syndromes
- Evaluate the site of resection for local recurrence of lesions
- Examine the colon in patients with heart or lung disease, patients unable to be sedated, and patients unable to undergo colonoscopy
- Failure to visualize the entire colon during conventional colonoscopy
- Identify metastases
- Investigate cause of positive occult blood test
- Investigate further after an abnormal barium enema
- Investigate further when flexible sigmoidoscopy is positive for polyps
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with the HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

POTENTIAL DIAGNOSIS

Normal findings in

- Normal colon and rectum, with no evidence of polyps or growths

Abnormal findings in

- Abnormal endoluminal wall of the colon
- Extraluminal extension of primary cancer
- Mesenteric and retroperitoneal lymphadenopathy
- Metachronous lesions
- Metastases of cancer
- Polyps or growths in colon or rectum
- Tumor recurrence after surgery

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the colon.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast mediums.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**

- ▶ Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a radiology department, usually by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 6 to 8 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site.**
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

- ▶ Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; ensure that food and fluids have been restricted for at least 6 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of contrast (if used), emergency drugs, and sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table.
- ▶ The colon is distended with room air or carbon dioxide by means of a rectal tube and balloon retention device. Maximal colonic distention is guided by patient tolerance.
- ▶ If IV contrast is used, a rapid series of images is taken during and after injection.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ The sequence of images is repeated in the prone position.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast media.

Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of occult blood testing, colonoscopy, or other cancer-screening procedures should be made after consultation between the patient and HCP. The American Cancer Society (ACS) recommends regular screening for colon cancer, beginning at age 50 yr for individuals without identified risk factors. Their recommendations for frequency of screening: annual for occult blood testing (fecal occult blood testing [FOBT] and fecal immunochemical testing [FIT]); every 5 yr for flexible sigmoidoscopy, double contrast barium enema, and CT colonography; and every 10 yr for colonoscopy. There are both advantages and disadvantages to the screening tests that are available today. Methods to use DNA testing of stool are being investigated and awaiting FDA approval. The DNA test is designed to identify abnormal changes in DNA from the cells in the lining of the colon that are normally shed and excreted in stool.

The DNA tests under development would use multiple markers to identify colon cancers with various, abnormal DNA changes and would be able to detect precancerous polyps. The most current guidelines for colon cancer screening of the general population as well as of individuals with increased risk are available from the ACS (www.cancer.org), U.S. Preventive Services Task Force (www.uspreventiveservicestaskforce.org), and the American College of Gastroenterology (www.gi.org).

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include barium enema, BUN, cancer antigens, capsule endoscopy, colonoscopy, CBC, CBC hematocrit, CBC hemoglobin, CT abdomen, creatinine, fecal analysis, KUB studies, MRI abdomen, PET pelvis, proctosigmoidoscopy, PT/INR, and US pelvis.

Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Computed Tomography, Pancreas

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), abdominal CT, helical/spiral CT.

COMMON USE: To visualize and assess the pancreas toward assisting in diagnosing tumors, masses, cancer, bleeding, infection, and abscess. Used as an evaluation tool for surgical, radiation, and medical therapeutic interventions.

AREA OF APPLICATION: Pancreas.

CONTRAST: With or without oral or IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) is a noninvasive procedure used to enhance certain anatomic views of the abdominal structures. It becomes an invasive procedure when contrast medium is used. CT of the pancreas aids in the diagnosis or evaluation of pancreatic cysts, pseudocysts, inflammation, tumors, masses, metastases, abscesses, and trauma. In all but the thinnest or most emaciated patients, the pancreas is surrounded by fat that clearly defines its margins. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images. Differences in tissue density are detected and recorded and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the pancreas are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions. The procedure may be repeated after intravenous injection of iodinated contrast medium for vascular evaluation or after oral ingestion of

contrast medium for evaluation of bowel and adjacent structures. The CT scan can be used to guide biopsy needles into areas of pancreatic masses to obtain tissue for laboratory analysis and for placement of needles to aspirate cysts or abscesses. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients who are claustrophobic.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate

to severe reactions to ionic contrast medium.

-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
-  Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
-  Patients with pheochromocytoma, **because iodinated contrast may cause a hypertensive crisis.**
-  Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Detect dilation or obstruction of the pancreatic ducts
- Differentiate between pancreatic disorders and disorders of the retroperitoneum
- Evaluate benign or cancerous tumors or metastasis to the pancreas
- Evaluate pancreatic abnormalities (e.g., bleeding, pancreatitis, pseudocyst, abscesses)
- Evaluate unexplained weight loss, jaundice, and epigastric pain
- Monitor and evaluate effectiveness of medical or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and contour of the pancreas, which lies obliquely in the upper abdomen

Abnormal findings in

- Acute or chronic pancreatitis
- Obstruction of the pancreatic ducts

- Pancreatic abscesses
- Pancreatic carcinoma
- Pancreatic pseudocyst
- Pancreatic tumor

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be

found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the abdomen and pancreatic area.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or other contrast medium.
- ▶ Obtain a history of the patient's gastrointestinal and hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) or a water soluble oral contrast beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.

- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; ensure that food and fluids have been restricted for at least 2 to 4 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.

- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

- ▶ Place the patient in the supine position on an examination table.

- ▶ If IV contrast medium is used, a rapid series of images is taken during and after injection.

- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.

- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.

- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.

- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain.

Immediately report symptoms to the appropriate HCP.

- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing,

treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include amylase, angiography of the abdomen, biopsy intestinal, BUN, cancer antigens, CBC hemoglobin, creatinine, ERCP, lipase, MRI abdomen, PT/INR, and US pancreas.
- ▶ Refer to the Gastrointestinal and Hepatobiliary systems tables at the end of the book for related tests by body system.

Computed Tomography, Pelvis

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), pelvis CT, helical/spiral CT.

COMMON USE: To visualize and assess pelvic structures and vascularities related to assisting in diagnosing bleeding, infection, masses, and cyst aspiration (needle-guided biopsy). Used to monitor the effectiveness of medical, radiation, and surgical therapeutic interventions.

AREA OF APPLICATION: Pelvis.

CONTRAST: With or without oral or IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) of the pelvis is a noninvasive procedure used to enhance certain anatomic views of the pelvic structures. It becomes an invasive procedure when intravenous contrast medium is used. During the procedure, the patient lies on

a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series

of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images. Differences in tissue density are detected and recorded and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the pelvic structures and associated vascular system are reviewed to allow differentiation of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure may be repeated after intravenous injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for evaluation of bowel and adjacent structures. The CT scan can be used to guide biopsy needles into areas of pelvic masses to obtain tissue for laboratory analysis and for placement of needles to aspirate cysts or abscesses. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far

outweigh the risk of radiation exposure to the fetus and mother.

- ◆ Patients who are claustrophobic.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
- ◆ Patients with pheochromocytoma, **because iodinated contrast may cause a hypertensive crisis.**

- ◆ Patients with bleeding disorders or receiving anticoagulant therapy ***because the puncture site may not stop bleeding.***

INDICATIONS

- Assist in differentiating between benign and malignant tumors
- Detect tumor extension of masses and metastasis into the pelvic area
- Differentiate infectious from inflammatory processes
- Evaluate pelvic lymph nodes
- Evaluate cysts, masses, abscesses, ureteral and bladder calculi, gastrointestinal (GI) bleeding and obstruction, and trauma
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of pelvic organs and vascular system

Abnormal findings in

- Bladder calculi
- Ectopic pregnancy
- Fibroid tumors
- Hydrosalpinx
- Ovarian cyst or abscess
- Primary and metastatic neoplasms

CRITICAL FINDINGS ◆

- Ectopic pregnancy
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate

notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and can produce unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are

lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging**

Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation over-exposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the pelvis and pelvic organs.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast medium.
- ▶ Obtain a history of the patient's gastrointestinal, genitourinary, and reproductive systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that

barium studies were performed more than 4 days before the CT scan.

- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ Advise the patient that he or she may be requested to drink approximately 450 mL of a dilute barium solution

(approximately 1% barium) or a water soluble oral contrast beginning 1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.

- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations; ensure that food and fluids have been restricted for at least 2 to 4 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout

the procedure because movement produces unreliable results.

- ▶ Establish an IV fluid line for the injection of contrast, emergency drugs, and sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table.
- ▶ If IV contrast medium is used, a rapid series of images is taken during and after injection.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
 - ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.
 - ▶ Instruct the patient in the care and assessment of the site.
 - ▶ Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
 - ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
 - ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
 - ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
 - ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography pelvis, barium enema, BUN, calculus kidney stone panel, cancer antigens, CBC, CBC hematocrit, CBC hemoglobin, creatinine, HCG, IVP, KUB film, MRI abdomen, proctosigmoidoscopy, PT/INR, US pelvis, and UA.
- ▶ Refer to the Gastrointestinal, Genitourinary, and Reproductive systems tables at the end of the book for related tests by body system.

Computed Tomography, Pituitary

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), pituitary CT, helical/spiral CT.

COMMON USE: To visualize and assess portions of the brain and pituitary gland for cancer, tumor, and bleeding. Used as an evaluation tool for surgical, radiation, and medical therapeutic interventions.

AREA OF APPLICATION: Pituitary/brain.

CONTRAST: With or without IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) of the pituitary is a non-invasive procedure that enhances certain anatomic views of the pituitary gland and perisellar region. It becomes invasive when a contrast

medium is used. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray

tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images. This procedure aids in the evaluation of pituitary adenoma, craniopharyngioma, meningioma, aneurysm, metastatic disease, exophthalmos, and cysts. Visualization of bony septa in the sphenoid sinus and evaluation for nonpneumatization of the sphenoid sinus are best performed with this procedure. Differences in tissue density are detected and recorded and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the pituitary and associated vascular system are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure may be repeated after intravenous injection of iodinated contrast medium for vascular evaluation. Images can be recorded on photographic or x-ray film or stored in digital format as digitized computer data. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients who are claustrophobic.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**

-  Patients with pheochromocytoma, **because iodinated contrast may cause a hypertensive crisis.**
-  Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Assist in differentiating between benign and malignant tumors
- Detect aneurysms and vascular abnormalities
- Detect congenital anomalies, such as partially empty sella
- Detect tumor extension of masses and metastasis
- Determine pituitary size and location in relation to surrounding structures
- Evaluate cysts, masses, abscesses, and trauma
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of the pituitary fossa, cavernous sinuses, and vascular system

Abnormal findings in

- Abscess
- Adenoma
- Aneurysm
- Chordoma
- Craniopharyngioma
- Cyst
- Meningioma
- Metastasis
- Pituitary hemorrhage

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Retained contrast from a previous radiological procedure.

- Metallic objects (e.g., jewelry, dentures, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the brain and pituitary gland.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast medium.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr.

Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH and challenge tests, BUN, CT angiography, CBC, CBC hematocrit, CBC hemoglobin, CT brain, cortisol and challenge tests, creatinine, MRA, MRI brain, PET brain, and PT/INR.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Computed Tomography, Renal

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), kidney CT, helical/spiral CT.

COMMON USE: To visualize and assess the kidney and surrounding structures to assist in diagnosing cancer, tumor, infection, and congenital anomalies. Used to evaluate the success of therapeutic medical, surgical, and radiation interventions.

AREA OF APPLICATION: Kidney.

CONTRAST: With or without oral or IV iodinated contrast medium.

DESCRIPTION: Renal computed tomography (CT) is a noninvasive procedure used to enhance certain anatomic views of the renal structures. It becomes an invasive procedure when contrast medium is used. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images.

CT provides unique cross-sectional anatomic information and is unsurpassed in evaluating lesions containing fat or calcium. Differences in tissue density are detected and recorded and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the kidneys and associated vascular system are reviewed to allow differentiation of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure may be repeated after IV injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for evaluation of bowel and adjacent structures. The CT scan can be used to guide biopsy needles into areas of suspected tumors in the kidneys to obtain tissue for laboratory analysis and to guide placement of catheters for drainage of renal abscesses. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients who are claustrophobic.
-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).
Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) ***because iodinated contrast is nephrotoxic.***
-  Elderly and compromised patients who are chronically dehydrated before the test, ***because of their risk of contrast-induced renal failure.***

-  Patients with pheochromocytoma, ***because iodinated contrast may cause a hypertensive crisis.***
-  Patients with bleeding disorders or receiving anticoagulant therapy ***because the puncture site may not stop bleeding.***

INDICATIONS

- Aid in the diagnosis of congenital anomalies, such as polycystic kidney disease, horseshoe kidney, absence of one kidney, or kidney displacement
- Aid in the diagnosis of perirenal hematomas and abscesses and assist in localizing for drainage
- Assist in differentiating between benign and malignant tumors
- Assist in differentiating between an infectious and an inflammatory process
- Detect aneurysms and vascular abnormalities
- Detect bleeding or hyperplasia of the adrenal glands
- Detect tumor extension of masses and metastasis into the renal area
- Determine kidney size and location in relation to the bladder in post-transplant patients
- Determine presence and type of adrenal tumor, such as benign adenoma, cancer, or pheochromocytoma
- Evaluate abnormal fluid accumulation around the kidney
- Evaluate cysts, masses, abscesses, renal calculi, obstruction, and trauma
- Evaluate spread of a tumor or invasion of nearby retroperitoneal organs
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of kidneys and vascular system

Abnormal findings in

- Adrenal tumor or hyperplasia
- Congenital anomalies, such as polycystic kidney disease, horseshoe kidney, absence of one kidney, or kidney displacement
- Dilation of the common hepatic duct, common bile duct, or gallbladder
- Renal artery aneurysm
- Renal calculi and ureteral obstruction
- Renal cell carcinoma
- Renal cysts or abscesses
- Renal laceration, fracture, tumor, and trauma
- Perirenal abscesses and hematomas
- Primary and metastatic neoplasms

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the kidney.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast mediums.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Advise the patient that he or she may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) or a water-soluble oral contrast beginning 1 hr

before the examination. This is administered to distinguish GI organs from the other abdominal organs.

- ▶ Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluids, and medication restrictions for 2 to 4 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use non-ionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the

gown, robe, and foot coverings provided.

- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Establish an IV fluid line for the injection of contrast, emergency drugs, and sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table.
- ▶ If IV contrast is used, a rapid series of images is taken during and after injection.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, angiography adrenal, renal biopsy, BUN, calculus/kidney stone panel, catecholamines, CBC, CBC hematocrit, CBC hemoglobin, creatinine, CT abdomen, homovanillic acid, IVP, KUB, MRI abdomen, PT/INR, US renal, and VMA.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Computed Tomography, Spine

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), spine CT, CT myelogram.

C

COMMON USE: To visualize and assess spinal structure related to tumor, injury, bleeding, and infection. Used as an evaluation tool for surgical, radiation, and medical therapeutic interventions.

AREA OF APPLICATION: Spine.

CONTRAST: With or without oral or IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) of the spine is a noninvasive procedure that enhances certain anatomic views of the spinal structures. CT scanning is more versatile than conventional radiography and can easily detect and identify tumors and their types. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images. Differences in tissue density are detected and

recorded and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the spine and associated vascular system are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure may be repeated after intravenous injection of iodinated contrast medium for vascular evaluation. CT scanning can be used to guide biopsy needles into areas of suspected tumor to obtain tissue for laboratory analysis and to guide placement of catheters for drainage of abscesses. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients who are claustrophobic.

- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs), **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
- ◆ Patients with pheochromocytoma, **because iodinated contrast may cause a hypertensive crisis.**
- ◆ Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Assist in differentiating between benign and malignant tumors
- Detect congenital spinal anomalies, such as spina bifida, meningocele, and myelocoele
- Detect herniated intervertebral disks
- Detect paraspinous cysts
- Detect vascular malformations
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal density, size, position, and shape of spinal structures

Abnormal findings in

- Congenital spinal malformations, such as meningocele, myelocoele, or spina bifida
- Herniated intervertebral disks
- Paraspinal cysts
- Spinal tumors
- Spondylosis (cervical or lumbar)
- Vascular malformations

CRITICAL FINDINGS ◆

- Cord compression
- Fracture
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported

information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric &**

Geriatric Imaging Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the spine.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast medium.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including

examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.

- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs and nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

▶ Note that there are no food, fluid, or medication restrictions unless by medical direction. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.

- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with medication restrictions and pretesting preparations.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

- ▶ If ordered, establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table.
- ▶ If IV contrast medium is used, a rapid series of images is taken during and after injection.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea,

hypertension, palpitations, nausea, or vomiting.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALP, BUN, bone scan, CBC, CBC hematocrit, CBC hemoglobin, creatinine, MRI bone, PT/INR, and radiography of the bones.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Computed Tomography, Spleen

SYNONYM/ACRONYM: Computed axial tomography (CAT), computed transaxial tomography (CTT), helical/spiral CT, splenic CT.

COMMON USE: To visualize and assess the spleen and surrounding structure for tumor, bleeding, infection, and trauma. Used to monitor the effectiveness of medical, surgical, and radiation therapeutic interventions.

AREA OF APPLICATION: Abdomen/spleen.

CONTRAST: With or without oral or IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) of the spleen is a noninvasive procedure that enhances certain anatomic views of the splenic structures. It becomes an invasive procedure with the use of contrast medium. The spleen is not often the organ of interest when abdominal CT scans are obtained. However, a wide variety of splenic variations and abnormalities may be detected on abdominal scans designed to evaluate the liver, pancreas, or retroperitoneum. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with

standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images. Differences in tissue density are detected and recorded and are viewable as computerized digital images. Slices or thin sections of certain anatomic views of the spleen and associated vascular system are reviewed to allow differentiation of solid, cystic, inflammatory, or vascular lesions, as well as identification of suspected hematomas and aneurysms. The procedure may be repeated after IV injection of iodinated contrast medium for vascular evaluation or after oral ingestion of contrast medium for evaluation of bowel and adjacent structures. The CT scan can be used to guide biopsy needles into areas of splenic masses to obtain tissue for laboratory analysis and for placement of needles to aspirate cysts or abscesses. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients who are claustrophobic.
-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).
Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) because iodinated contrast is nephrotoxic
-  Elderly and compromised patients who are chronically dehydrated before the test, **because**

of their risk of contrast-induced renal failure.

-  Patients with pheochromocytoma, **because iodinated contrast may cause a hypertensive crisis.**
-  Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Assist in differentiating between benign and malignant tumors
- Detect tumor extension of masses and metastasis
- Differentiate infectious from inflammatory processes
- Evaluate cysts, masses, abscesses, and trauma
- Evaluate the presence of an accessory spleen, polysplenia, or asplenia
- Evaluate splenic vein thrombosis
- Monitor and evaluate effectiveness of medical, radiation, or surgical therapies

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of the spleen and associated vascular system

Abnormal findings in

- Abdominal aortic aneurysm
- Hematomas
- Hemoperitoneum
- Primary and metastatic neoplasms
- Splenic cysts or abscesses
- Splenic laceration, tumor, infiltration, and trauma

CRITICAL FINDINGS

- Abscess
- Hemorrhage
- Laceration

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the abdomen and spleen.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast medium.
- ▶ Obtain a history of the patient's hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure results of coagulation testing are obtained and recorded prior to the

procedure; BUN and creatinine results are also needed if contrast medium is to be used.

- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ The patient may be requested to drink approximately 450 mL of a dilute barium solution (approximately 1% barium) or a water soluble oral contrast beginning

1 hr before the examination. This is administered to distinguish GI organs from the other abdominal organs.

- ▶ Inform the patient that he or she may experience nausea, a feeling of warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluids, and medication restrictions for 2 to 4 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.

- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.
- ▶ Administer an anti-anxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table.
- ▶ If IV contrast medium is used, a rapid series of images is taken during and after injection.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast medium is used.
- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if

temperature is elevated. Protocols may vary among facilities.

- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Inform the patient that diarrhea may occur after ingestion of oral contrast medium.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography abdomen, BUN, CBC, CBC hematocrit, CBC hemoglobin, creatinine, KUB film, MRI abdomen, PT/INR, and US liver.
- ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Computed Tomography, Thoracic

SYNONYM/ACRONYM: Chest CT, computed axial tomography (CAT), computed transaxial tomography (CTT), helical/spiral CT.

C

COMMON USE: To visualize and assess structures within the thoracic cavity such as the heart, lungs, and mediastinal structures to evaluate for aneurysm, cancer, tumor, and infection. Used as an evaluation tool for surgical, radiation, and medical therapeutic interventions.

AREA OF APPLICATION: Thorax.

CONTRAST: With or without oral or IV iodinated contrast medium.

DESCRIPTION: Computed tomography (CT) of the thorax is more detailed than a chest x-ray. It is a noninvasive procedure used to enhance certain anatomic views of the lungs, heart, and mediastinal structures. It becomes invasive when a contrast medium is used. During the procedure, the patient lies on a motorized table. The table is moved in and out of a circular opening in a doughnut-like device called a *gantry*, which houses the x-ray tube and associated electronics. A beam of x-rays irradiates the patient as the table moves in and out of the scanner in a series of phases. Multiple detectors rotate around the patient to produce cross-sectional views or slices. The slices can be viewed individually or as a three-dimensional image. Multislice or multidetector CT (MDCT) scanners continuously collect images in a helical or spiral fashion instead of a series of individual images as with standard scanners. Helical CT is capable of collecting many images over a short period of time (seconds), is very sensitive in identifying small abnormalities, and produces high-quality images.

Slices or thin sections of certain anatomic views of the spine, spinal cord, and lung areas are reviewed to allow differentiations of solid, cystic, inflammatory, or vascular lesions. Tumor progression, before and after therapy, and effectiveness of medical interventions may be monitored by CT scanning.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients who are claustrophobic.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required

for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of non-ionic contrast or an alternative non-contrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure.**
- ◆ Patients with pheochromocytoma **because iodinated contrast may cause a hypertensive crisis.**
- ◆ Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Detect aortic aneurysms
- Detect bronchial abnormalities, such as stenosis, dilation, or tumor
- Detect lymphomas, especially Hodgkin's disease
- Detect mediastinal and hilar lymphadenopathy
- Detect primary and metastatic pulmonary, esophageal, or mediastinal tumors
- Detect tumor extension of neck mass to thoracic area
- Determine blood, fluid, or fat accumulation in tissues, pleuritic space, or vessels
- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate between benign and malignant tumors
- Differentiate infectious from inflammatory processes
- Differentiate tumor from tuberculosis
- Evaluate cardiac chambers and pulmonary vessels
- Evaluate the presence of plaque in cardiac vessels
- Identify or rule out thymoma in cases of diagnosed myasthenia gravis
- Monitor and evaluate effectiveness of medical or surgical therapeutic regimen

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, position, and shape of thoracic organs, tissues, and structures

Abnormal findings in

- Aortic aneurysm
- Chest, mediastinal, spine, or rib lesions
- Cysts or abscesses
- Enlarged lymph nodes
- Esophageal pathology, including tumors
- Hodgkin's disease
- Pleural effusion
- Pneumonitis
- Pneumothorax
- Pulmonary embolism

CRITICAL FINDINGS

- Aortic aneurysm
- Aortic dissection
- Pneumothorax
- Pulmonary embolism

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Patients with extreme claustrophobia unless sedation is given before the study.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the chest.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or contrast medium.
- ▶ Obtain a history of the patient's respiratory system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Ensure results of coagulation testing are obtained and recorded prior to the procedure; BUN and creatinine results are also needed if contrast medium is to be used.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before the CT scan.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient the procedure is usually performed in a radiology suite by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids (e.g., normal saline), anesthetics, contrast medium, or sedatives.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Inform the patient that he or she may experience nausea, a feeling of

warmth, a salty or metallic taste, or a transient headache after injection of contrast medium.

- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 2 to 4 hr prior to the procedure and to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Injection of the contrast through IV tubing into a blood vessel is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, cardiac arrhythmias, hematoma **related to blood leakage into the tissue following insertion of the IV needle**, or infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions for 2 to 4 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the

patient to remain still throughout the procedure because movement produces unreliable results.

- ▶ Establish an IV fluid line for the injection of contrast medium, emergency drugs, and sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in the supine position on an examination table.
- ▶ If IV contrast medium is used, a rapid series of images is taken during and after injection.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm) if contrast is used.
- ▶ The needle is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed, if contrast was used.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ If contrast was used, observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the insertion site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to increase fluid intake to help eliminate the contrast medium, if used.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include acetylcholine receptor antibody, biopsy bone marrow, BUN, chest x-ray, CBC, CBC hematocrit, CBC hemoglobin, creatinine, echocardiogram, gallium scan, lung scan, MRI chest, mediastinoscopy, MRI venography, pleural fluid analysis, and PT/INR.
- ▶ Refer to the Respiratory System table at the end of the book for related tests by body system.

Coombs' Antiglobulin, Direct

SYNONYM/ACRONYM: Direct antiglobulin testing (DAT).

COMMON USE: To detect associated conditions or drug therapies that can result in cell hemolysis, such as found in hemolytic disease of newborns, and hemolytic transfusion reactions.

SPECIMEN: Serum (1 mL) collected in a red-top tube and whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Agglutination) Negative (no agglutination).

DESCRIPTION: Direct antiglobulin testing (DAT) detects in vivo antibody sensitization of red blood cells (RBCs). Immunoglobulin G (IgG) produced in certain disease states or in response to certain drugs can coat the surface of RBCs, resulting in cellular damage and hemolysis. When DAT is performed, RBCs are taken from the patient's blood sample, washed with saline to remove residual globulins, and mixed with anti-human globulin reagent. If the anti-human globulin reagent causes agglutination of the patient's RBCs, specific antiglobulin reagents can be used to determine whether the patient's RBCs are coated with IgG, complement, or both. (See monograph titled "Blood Groups and Antibodies" and Appendix F online at DavisPlus for more information regarding transfusion reactions.)

This procedure is contraindicated for: N/A

INDICATIONS

- Detect autoimmune hemolytic anemia or hemolytic disease of the newborn
- Evaluate suspected drug-induced hemolytic anemia

- Evaluate transfusion reaction

POTENTIAL DIAGNOSIS

Positive findings in Antibodies formed during these circumstances or conditions attach to the patient's RBCs, and hemolysis occurs. Agglutination is graded from 1+ to 4+ in manual testing systems; with 4+ being the strongest degree of agglutination. Automated testing systems are capable of reporting 1+ to 4+ graded results, or providing images of the tested material so laboratory professionals can interpret the results, or providing computer assisted interpretation of the test results as positive or negative findings.

- Anemia (*autoimmune hemolytic, drug-induced*)
- Hemolytic disease of the newborn (*related to ABO or Rh incompatibility*)
- Infectious mononucleosis
- Lymphomas
- Mycoplasma pneumonia
- Paroxysmal cold hemoglobinuria (*idiopathic or disease related*)
- Passively acquired antibodies from plasma products
- Post-cardiac vascular surgery (*increased incidence of positive*)

DAT has been reported in patients following cardiac surgery, possibly related to mechanical RBC destruction while the patient is on cardiac bypass)

- Systemic lupus erythematosus and other connective tissue immune disorders
- Transfusion reactions (*related to blood incompatibility*)

Negative findings in

- Samples in which sensitization of erythrocytes has not occurred

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that may cause a positive DAT include acetaminophen, aminopyrine, aminosalicylic acid, ampicillin, antihistamines, aztreonam, cephalosporins, chlorinated hydrocarbon insecticides, chlorpromazine, chlorpropamide, cisplatin, clonidine, dipyron, ethosuximide, fenfluramine, hydralazine, hydrochlorothiazide, ibuprofen, insulin, isoniazid, levodo-

pa, mefenamic acid, melphalan, methadone, methicillin, methyldopa, moxalactam, penicillin, phenytoin, probenecid, procainamide, quinidine, quinine, rifampin, stibophen, streptomycin, sulfonamides, and tetracycline.

- Wharton's jelly may cause a false-positive DAT.
- Cold agglutinins and large amounts of paraproteins in the specimen may cause false-positive results.
- Newborns' cells may give negative results in ABO hemolytic disease.
- Tube methods for DAT are less sensitive than gel methods, and false-negative findings are possible in cases where weak, incompletely developed antigen sites on newborns' RBCs may not allow detectable amounts of anti-A and/or anti-B to bind to the RBC membrane. Neonates who have received multiple intrauterine transfusions of antigen-negative (group O) cells may also have a negative DAT because the results represent circulating donated red blood cells rather than the neonate's native red blood cells.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Injury risk (<i>Related to Rh incompatibility; blood incompatibility</i>)	Jaundice in newborn; infant cardiac stress (heart failure); infant death	Administer prescribed Rh-immune immunoglobulin to mother; obtain maternal blood type and crossmatch; use bilirubin light for newborn; use infant treatment with prescribed erythropoietin and iron supplements; administer prescribed blood transfusion to infant; follow blood transfusion guidelines; monitor degree

Problem	Signs & Symptoms	Interventions
Fear (<i>Related to possible loss of newly born child; long-term effects of elevated bilirubin</i>)	Expression of fear; preoccupation with fear; increased tension; parental complaints of diarrhea, nausea; parental expressions of fatigue or insomnia; crying; withdrawal; panic attacks	of jaundice and associated laboratory results (bilirubin); monitor HGB/HCT Access social services; provide specific and culturally appropriate education; assist the patient and family to recognize effective coping strategies; assist the patient to acknowledge fear; provide a safe environment to decrease fear; explore cultural influences that may enhance fear; utilize therapeutic touch as appropriate to decrease fear
Gas exchange (<i>Related to destruction of red cells secondary to maternal-child Rh incompatibility</i>)	Shortness of breath; orthopnea; cyanosis; increased heart rate; increased respiratory rate; use of respiratory accessory muscles	Auscultate and trend breath sounds; use pulse oximetry to monitor oxygenation; administer oxygen as ordered; collaborate with physician to consider intubation and/or mechanical ventilation; elevate the infant's head; administer ordered blood or blood products; monitor HGB/HCT

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient/parent this test can assist in assessing for disorders that break down red blood cells.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic system as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional

- supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. If a cord sample is to be taken from a newborn, inform parents that the sample will be obtained at the time of delivery and will not result in blood loss to the infant.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:**

Acute hemolytic reactions can be immediate and life threatening for patients of any age. Chronic hemolytic anemia is also a significant condition that requires timely identification of the problem in order to treat the condition. Assess the newborn's bilirubin and hematocrit levels. Increased bilirubin and decreased hematocrit may be indicative of RBC breakdown.

Kernicterus, or deposition of bilirubin in the brain, is a serious and significant development that can lead to permanent brain damage or death.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Cord specimens are obtained by inserting a needle attached to a syringe into the umbilical vein. The specimen is drawn into the syringe and gently expressed into the appropriate collection container.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and inform the postpartum patient of the implications of positive test results in cord blood; also assess newborn's bilirubin and hematocrit levels. The results

may indicate the need for immediate exchange transfusion of fresh whole blood that has been typed and cross-matched with the mother's serum in order to identify the presence of unusual antibodies. Observation of the neonatal patient, especially for the development of jaundice, is an important way to identify a hemolytic process. Facilities not equipped for neonatal exchange transfusion may elect to transfer the neonate to a facility where the appropriate level of care can be provided. Hand-Off communication is a standardized approach to sharing information in an effort to minimize the risk of error or injury during transition between caregivers. Use of the SBAR-R format (situation, background, assessment, recommendation, and read-back) may be used as a communication tool to ensure mutual understanding of the clinical situation.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Inform the postpartum patient of the implications of positive test results in cord blood.
- ▶ Prepare the newborn for exchange transfusion, on medical direction.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:**Knowledge**

- ▶ Parents state their understanding of the purpose for the recommended infant blood transfusion.
- ▶ Mother states her understanding of the purpose of Rh-immune immunoglobulin injection in relation to future pregnancies.

Skills

- ▶ Parents demonstrate proficiency in placing the infant under the bilirubin light and adhering to identified precautions.

Parents demonstrate proficiency in administering prescribed iron supplements to infant.

Attitude

- Complies with the request to bring the infant in for bilirubin blood checks as designated by the HCP
- Complies with the recommendation to receive Rh-immune immunoglobulin

RELATED MONOGRAPHS:

- Related tests include bilirubin, blood groups and antibodies, CBC hematocrit,

CBC hemoglobin, Coombs' indirect antiglobulin (IAT), Ham's test, and haptoglobin.

- Refer to Appendix F online at DavisPlus at the end of the book for further information regarding laboratory studies used in the investigation of transfusion reactions, findings, and potential nursing interventions associated with types of transfusion reactions.
- Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Coombs' Antiglobulin, Indirect

SYNONYM/ACRONYM: Indirect antiglobulin test (IAT), antibody screen.

COMMON USE: To check recipient serum for antibodies prior to blood transfusion.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method:Agglutination) Negative (no agglutination).

DESCRIPTION: The indirect antiglobulin test (IAT) detects and identifies unexpected circulating complement molecules or antibodies in the patient's serum. The first use of this test was for the detection and identification of anti-D using an indirect method. The test is now commonly used to screen a patient's serum for the presence of antibodies that may react against transfused red blood cells (RBCs). During testing, the patient's serum is allowed to incubate with reagent RBCs. The reagent RBCs used are from group O donors and have most of the clinically significant antigens present (D, C, E, c, e, K, M, N, S, s, Fy^a, Fy^b, Jk^a, and Jk^b). Antibodies present in the patient's serum coat antigenic sites on the RBC membrane. The reagent cells are washed with saline to

remove any unbound antibody. Antihuman globulin is added in the final step of the test. If the patient's serum contains antibodies, the antihuman globulin will cause the antibody-coated RBCs to stick together or agglutinate. (See monograph titled "Blood Groups and Antibodies" and Appendix F online at DavisPlus for more information regarding transfusion reactions.)

This procedure is contraindicated for: N/A

INDICATIONS

- Detect other antibodies in maternal blood that can be potentially harmful to the fetus
- Determine antibody titers in Rh-negative women sensitized by an Rh-positive fetus

- Screen for antibodies before blood transfusions
- Test for the weak Rh-variant antigen D^u. Development of anti-D antibodies occur when Rh-negative women become sensitized by an Rh-positive fetus. Antibody titers should be performed as soon as a subsequent pregnancy becomes known in order to appropriately anticipate management of hemolytic disease of the newborn (HDN). The IAT has also been used to test for the weak Rh-variant antigen D^u. Modern technology and more potent reagents provide better sensitivity, and for this reason women who have the D^u variant will likely be typed as Rh-positive. It is for this reason the AABB has determined weak D testing is no longer necessary to be used on obstetric patients. Women who have the weak D variant are tested using less-sensitive reagents, and those typed as Rh-negative will be candidates for immunization with Rh-immune globulin. Administration of Rh-immune globulin to these candidates is not harmful. Whether the test is used currently varies among facilities.

POTENTIAL DIAGNOSIS

Positive findings in

Circulating antibodies or medications attach to the patient's RBCs, and hemolysis occurs. Agglutination is graded from 1+ to 4+ in manual testing systems; with 4+ being the strongest degree of agglutination. Automated testing systems are capable of reporting 1+ to 4+ graded results, or providing images of the tested material so laboratory professionals can interpret the results, or providing computer assisted interpretation of the test results as positive or negative findings.

- Hemolytic anemia (*drug-induced or autoimmune*)

- Hemolytic disease of the newborn (*related to ABO or Rb incompatibility*)
- Incompatible crossmatch
- Infections (mycoplasma pneumonia, mononucleosis)

Negative findings in

- Samples in which the patient's antibodies exhibit dosage effects (i.e., stronger reaction with homozygous than with heterozygous expression of an antigen) and reagent erythrocyte antigens contain single-dose expressions of the corresponding antigen (heterozygous)
- Samples in which reagent erythrocyte antigens are unable to detect low-prevalence antibodies
- Samples in which sensitization of erythrocytes has not occurred (true negative, complete absence of antibodies)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may cause a positive IAT include meropenem, methyl dopa, penicillin, phenacetin, quinidine, and rifampin.
- Recent administration of dextran, whole blood or fractions, or IV contrast media can result in a false-positive reaction.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for blood compatibility prior to transfusion.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's hematopoietic system as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture. Prenatal mothers may be concerned about blood collection from their newborn. Explain that a cord sample of blood taken from the infant at the time of delivery does not result in infant blood loss.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ There are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

- Acute hemolytic reactions, whether immune mediated or developed due to drug sensitivities, can be immediate and life threatening. Chronic hemolytic anemia is also a significant condition that requires timely identification of the problem in order to treat the condition. Positive findings in the pregnant patient may require further investigation by amniocentesis. Any sampling method that involves penetration of natural tissue barriers carries the risk of infection.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
 - ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the

- specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
 - ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient. It is important for the patient to be made aware of the presence of unusual antibodies. A person may have circulating antibodies, other than ABO/Rh group antibodies, which may respond to transfused blood. The antibodies attach to the person's red blood cells, damaging the integrity of the cell wall, and hemolysis occurs. Therefore, it is important to screen for the presence of antibodies in the recipient's serum prior to transfusion. Unexpected antibodies, other than ABO/Rh, can develop at any time. If present in maternal blood, they can be potentially harmful to the fetus, which makes antibody screening an important test in prenatal care.
- ▶ Inform pregnant women that negative tests during the first 12 wk of gestation should be repeated at 28 wk to rule out the presence of an antibody.
- ▶ Positive test results in pregnant women after 28 wk of gestation indicate the need for antibody identification testing.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include bilirubin, blood groups and antibodies, CBC

hematocrit, CBC hemoglobin, Coombs' direct antiglobulin (DAT), and haptoglobin.

- Refer to Appendix F online at DavisPlus at the end of the book for further information regarding laboratory studies used in the investigation of

transfusion reactions, findings and potential nursing interventions associated with types of transfusion reactions.

- Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Copper

SYNONYM/ACRONYM: Cu.

COMMON USE: To evaluate and monitor exposure to copper and to assist in diagnosing Wilson's disease.

SPECIMEN: Serum (1 mL) collected in a royal blue-top, trace element-free tube.

NORMAL FINDINGS: (Method: Inductively coupled plasma-mass spectrometry)

Age	Conventional Units	SI Units (Conventional Units × 0.157)
Newborn–5 days	9–46 mcg/dL	1.4–7.2 micromol/L
1–5 yr	80–150 mcg/dL	12.6–23.6 micromol/L
6–9 yr	84–136 mcg/dL	13.2–21.4 micromol/L
10–14 yr	80–120 mcg/dL	12.6–18.8 micromol/L
15–19 yr	80–171 mcg/dL	12.6–26.8 micromol/L
Adult		
Male	71–141 mcg/dL	11.1–22.1 micromol/L
Female	80–155 mcg/dL	12.6–24.3 micromol/L
Pregnant female	118–302 mcg/dL	18.5–47.4 micromol/L

Values for African Americans are 8% to 12% higher. Values increase in older adults.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Ceruloplasmin is an acute-phase reactant protein and the main protein binder of copper; therefore, copper levels will be increased in many inflammatory conditions, including cancer. Estrogens increase

levels of binding protein; therefore, copper is elevated in pregnancy and estrogen therapy.

- Anemias (*related to increased RBC production*)
- Ankylosing rheumatoid spondylitis
- Biliary cirrhosis (*related to release from damaged liver tissue*)
- Collagen diseases
- Complications of renal dialysis (*trace element disturbances*)

related to contamination from dialysate fluid and the disease process itself can be significant and can compound over time)

- Hodgkin's disease
- Infections
- Inflammation
- Leukemia
- Malignant neoplasms
- Myocardial infarction (MI) *(a correlation exists among copper levels, CK, and LDH in MI; the pathophysiology is unclear, but some studies indicate a relationship between trace metal levels and risk of acute MI)*
- Pellagra *(related to niacin deficiency; niacin is an essential cofactor in reactions involving copper)*
- Poisoning from copper-contaminated solutions or insecticides *(related to excessive accumulation due to environmental exposure)*
- Pregnancy
- Pulmonary tuberculosis
- Rheumatic fever
- Rheumatoid arthritis
- Systemic lupus erythematosus
- Thalassemias *(related to zinc deficiency of thalassemia and increased rate of release from hemolyzed RBCs; copper and zinc compete for the same binding sites so that a deficiency in one results in an increase of the other)*
- Thyroid disease (hypothyroid or hyperthyroid) *(related to stimulation of thyroid hormone production by copper)*
- Trauma
- Typhoid fever
- Use of copper intrauterine device *(related to copper leaching from the device)*

Decreased in

- Burns *(related to loss of stores in tissue and possibly to competitive inhibition of zinc-containing medications or vitamins administered as part of burn therapy)*
- Cystic fibrosis *(related to inadequate intake and absorption)*
- Dysproteinemia *(related to decreased transport to and from stores)*
- Infants *(related to inadequate intake of milk or consumption of milk deficient in copper; especially premature infants)*
- Iron-deficiency anemias (some) *(related to decreased absorption of iron from the intestines and transfer from tissues to plasma; it is essential to hemoglobin formation)*
- Long-term total parenteral nutrition *(related to inadequate intake)*
- Malabsorption disorders (celiac disease, tropical sprue) *(related to inadequate absorption)*
- Malnutrition *(related to inadequate intake)*
- Menkes' disease *(evidenced by a severe genetic X-linked defect causing failed transport to the liver and tissues)*
- Nephrotic syndrome *(related to loss of transport proteins)*
- Occipital horn syndrome (OHS) *(evidenced by an inherited disorder of copper metabolism; similar to Menkes' disease)*
- Wilson's disease *(evidenced by a genetic defect causing failed transport to the liver and tissues)*

CRITICAL FINDINGS: N/A

Cortisol and Challenge Tests

SYNONYM/ACRONYM: Hydrocortisone, compound E

COMMON USE: To assist in diagnosing adrenocortical insufficiency such as found in Cushing's syndrome and Addison's disease.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable. Care must be taken to use the same type of collection container if serial measurements are to be taken.

Procedure	Indications	Medication Administered	Recommended Collection Times
ACTH stimulation, rapid test	Suspect adrenal insufficiency (Addison's disease) or congenital adrenal hyperplasia	1 mcg (low-dose physiologic protocol) cosyntropin IM or IV; 250 mcg (standard pharmacologic protocol) cosyntropin IM or IV	3 cortisol levels: baseline immediately before bolus, 30 min after bolus, and 60 min after bolus. Note: Baseline and 30 min levels are adequate for accurate diagnosis using either dosage; low dose protocol sensitivity is most accurate for 30 min level only
CRH stimulation	Differential diagnosis between ACTH-dependent conditions such as Cushing's disease (pituitary source) or Cushing's syndrome	IV dose of 1 mg/kg ovine or human CRH	8 cortisol and 8 ACTH levels: baseline collected 15 min before injection, 0 min before injection, and then 5, 15, 30, 60, 120, and 180 min after injection

Procedure	Indications	Medication Administered	Recommended Collection Times
Dexamethasone suppression (overnight)	(ectopic source) and ACTH-independent conditions such as Cushing's syndrome (adrenal source) Differential diagnosis between ACTH-dependent conditions such as Cushing's disease (pituitary source) or Cushing's syndrome (ectopic source) and ACTH-independent conditions such as Cushing's syndrome (adrenal source)	Oral dose of 1 mg dexamethasone (Decadron) at 11 p.m.	Collect cortisol at 8 a.m. on the morning after the dexamethasone dose
Metyrapone stimulation (overnight)	Suspect hypothalamic/pituitary disease such as adrenal insufficiency, ACTH-dependent conditions such as Cushing's disease (pituitary source) or Cushing's syndrome (ectopic source), and ACTH-	Oral dose of 30 mg/kg metyrapone with snack at midnight	Collect cortisol and ACTH at 8 a.m. on the morning after the metyrapone dose

(table continues on page 610)

Procedure	Indications	Medication Administered	Recommended Collection Times
	independent conditions such as Cushing's syndrome (adrenal source)		

ACTH = adrenocorticotrophic hormone; CRH = corticotropin-releasing hormone; IM = intramuscular; IV = intravenous.

NORMAL FINDINGS: (Method: Immunochemiluminescent assay)

Cortisol

Time	Conventional Units	SI Units (Conventional Units × 27.6)
8 a.m.		
Birth–11 yr	10–340 mcg/dL	276–9384 nmol/L
12–18 yr	10–280 mcg/dL	276–7728 nmol/L
Adult/older adult	5–25 mcg/dL	138–690 nmol/L
4 p.m.		
Birth–11 yr	10–330 mcg/dL	276–9108 nmol/L
12–18 yr	10–272 mcg/dL	276–7507 nmol/L
Adult/older adult	3–16 mcg/dL	83–442 nmol/L

Long-term use of corticosteroids in patients, especially older adults, may be reflected by elevated cortisol levels.

ACTH Challenge Tests

ACTH (Cosyntropin) Stimulated, Rapid Test	Conventional Units	SI Units (Conventional Units × 27.6)
Baseline	Cortisol greater than 5 mg/dL	Greater than 138 nmol/L
30- or 60-min response	Cortisol 18–20 mcg/dL or incremental increase of 7 mcg/dL over baseline value	497–552 nmol/L or incremental increase of 193.2 nmol/L over baseline value

Corticotropin-Releasing Hormone Stimulated Test

Conventional Units

Cortisol peaks at greater than 20 mcg/dL within 30–60 min

SI Units (Conventional Units × 27.6)

Greater than 552 nmol/L

Corticotropin-Releasing Hormone Stimulated Test**Conventional Units**

ACTH increases twofold to fourfold within 30–60 min

SI Units (Conventional Units \times 0.22)

Twofold to fourfold increase within 30–60 min

Dexamethasone Suppressed Overnight Test**Conventional Units**

Cortisol less than 1.8 mcg/dL next day

SI Units (Conventional Units \times 27.6)

Less than 49.7 nmol/L

Metrapone Stimulated Overnight Test**Conventional Units**

Cortisol less than 3 mcg/dL next day

SI Units (Conventional Units \times 27.6)

Less than 83 nmol/L

ACTH greater than 75 pg/mL

SI Units (Conventional Units \times 0.22)

Greater than 16.5 pmol/L

11-deoxycortisol greater than 7 mcg/dL

SI Units (Conventional Units \times 28.9)

Greater than 202 nmol/L

DESCRIPTION: Cortisol (hydrocortisone) is the predominant glucocorticoid secreted by the adrenal glands in response to pituitary adrenocorticotropic hormone (ACTH). Cortisol is responsible for a number of regulatory functions which include stimulation of gluconeogenesis (generation of glucose from amino acids by the liver), breaking down fats to generate energy, acting as an insulin antagonist by increasing glucose levels, responding to stress, and suppressing inflammation. Measuring levels of cortisol in

blood is the best indicator of adrenal function. Cortisol secretion varies diurnally, with highest levels occurring on awakening and lowest levels occurring late in the day, although bursts of cortisol excretion can occur at night. This pattern may be reversed in individuals who sleep during daytime hours and are active during nighttime hours. Cortisol and ACTH test results are evaluated together because they each control the other's concentrations (i.e., any change in one causes a change in the other). ACTH levels

exhibit a diurnal variation, peaking between 6 and 8 a.m. and reaching the lowest point between 6 and 11 p.m. (See monograph titled “Adrenocorticotropic Hormone [and Challenge Tests].”) Salivary cortisol levels are known to parallel blood levels and can be used to screen for Cushing’s disease and Cushing’s syndrome.

There are three main conditions that can result from an imbalance in cortisol levels. Cushing’s syndrome is a complex condition that results from excessive levels of cortisol, regardless of the cause. Cushing’s disease is a condition in which the pituitary gland releases too much ACTH resulting in overproduction of cortisol. Addison’s disease is caused by failure of the adrenal glands to produce cortisol.

This procedure is contraindicated for

-  Patients with suspected adrenal insufficiency should not undergo the metyrapone stimulation test because it may induce an acute adrenal crisis, a life-threatening condition, in patients whose adrenal function is already compromised.

INDICATIONS

- Detect adrenal hyperfunction (Cushing’s syndrome)
- Detect adrenal hypofunction (Addison’s disease)

POTENTIAL DIAGNOSIS

The dexamethasone suppression test is useful in differentiating the causes for increased cortisol levels. Dexamethasone is a synthetic steroid that suppresses secretion of ACTH. With this test, a baseline

morning cortisol level is collected, and the patient is given a 1-mg dose of dexamethasone at bedtime. A second specimen is collected the following morning. If cortisol levels have not been suppressed, adrenal adenoma may be suspected. The dexamethasone suppression test also produces abnormal results in patients with psychiatric illnesses.

The corticotropin-releasing hormone (CRH) stimulation test works as well as the dexamethasone suppression test in distinguishing Cushing’s disease from conditions in which ACTH is secreted ectopically. In this test, cortisol levels are measured after an injection of CRH. A fourfold increase in cortisol levels above baseline is seen in Cushing’s disease. No increase in cortisol is seen if ectopic ACTH secretion is the cause.

The ACTH (cosyntropin)-stimulated rapid test is used when adrenal insufficiency is suspected. Cosyntropin is a synthetic form of ACTH. A baseline cortisol level is collected before the injection of cosyntropin. Specimens are subsequently collected at 30- and 60-min intervals. If the adrenal glands are functioning normally, cortisol levels rise significantly after administration of cosyntropin.

The metyrapone stimulation test is used to distinguish corticotropin-dependent (pituitary Cushing’s disease and ectopic Cushing’s disease) from corticotropin-independent (carcinoma of the lung or thyroid) causes of increased cortisol levels. Metyrapone inhibits the conversion of 11-deoxycortisol to cortisol. Cortisol levels should decrease to less than 3 mcg/dL if normal pituitary stimulation by ACTH occurs after an oral dose of metyrapone. Specimen collection and administration of the medication are

performed as with the overnight dexamethasone test.

Increased in

Conditions that result in excessive production of cortisol.

- Adrenal adenoma
- Cushing's syndrome
- Ectopic ACTH production
- Hyperglycemia

- Pregnancy
- Stress

Decreased in

Conditions that result in adrenal hypofunction and corresponding low levels of cortisol.

- Addison's disease
- Adrenogenital syndrome
- Hypopituitarism

Summary of the Relationship Between Cortisol and ACTH Levels in Conditions Affecting the Adrenal and Pituitary Glands

Disease	Cortisol Level	ACTH Level
Addison's disease (adrenal insufficiency)	Decreased	Increased
Cushing's disease (pituitary adenoma)	Increased	Increased
Cushing's syndrome related to ectopic source of ACTH	Increased	Increased
Cushing's syndrome (ACTH independent; adrenal cancer or adenoma)	Increased	Decreased
Congenital adrenal hyperplasia	Decreased	Increased

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that may increase cortisol levels include anticonvulsants, clomipramine, corticotropin, cortisone, CRH, ether, fenfluramine, gemfibrozil, hydrocortisone, insulin, lithium, methadone, metoclopramide, mifepristone, naloxone, opiates, oral contraceptives, ranitidine, tetracosactrin, and vasopressin.
- Drugs and substances that may decrease cortisol levels include barbiturates, beclomethasone, betamethasone, clonidine, desoximetasone, dexamethasone, ephedrine, etomidate, flucinolone, ketoconazole, levodopa,

lithium, methylprednisolone, metyrapone, midazolam, morphine, nitrous oxide, oxazepam, phenytoin, ranitidine, and trimipramine.

- Test results are affected by the time this test is done because cortisol levels vary diurnally.
- Stress and excessive physical activity can produce elevated levels.
- Normal values can be obtained in the presence of partial pituitary deficiency.
- Recent radioactive scans within 1 wk of the test can interfere with test results.
-  Metyrapone may cause gastrointestinal distress and/or confusion. Administer oral dose of metyrapone with milk and snack.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Body image <i>(Related to increased androgen production [virilism, hirsutism]; wasting of muscle and bone matrix; capillary fragility; purple striae; slender limbs; abnormal fat distribution [buffalo hump])</i>	Negative verbalization of altered physical appearance; preoccupation with physical body changes; distress and refusal to talk about changed appearance; negative verbalization about changes in appearance; using clothing to conceal body changes	Assess the patient's perception of physical changes; note the frequency of negative comments about changed physical state; assist in the identification of positive coping strategies to address changed physical appearance; provide reassurance that changes in physical appearance will improve as hormones return to normal level; provide a referral to local support groups
Infection risk <i>(Related to impaired immune response secondary to elevated cortisol level)</i>	Delayed wound healing; inhibited collagen formation; impaired blood flow to edematous tissues; symptoms of infection (temperature; increased heart rate; increased blood pressure; shaking; chills; mottled skin; lethargy; fatigue; swelling; edema; pain; localized pressure; diaphoresis; night sweats; confusion; vomiting; nausea; headache)	Decrease exposure to environment by placing the patient in a private room; monitor and trend vital signs; monitor and trend laboratory values that would indicate an infection (white blood cells [WBC], C-reactive protein [CRP]); promote good hygiene; assist with hygiene as needed; administer prescribed antibiotics, antipyretics; provide cooling measures; administer prescribed intravenous fluids; monitor vital signs and trend temperatures; encourage oral fluids; adhere to standard or universal precautions; isolate as appropriate; obtain cultures as ordered; encourage use of lightweight clothing and bedding

Problem	Signs & Symptoms	Interventions
Fluid volume (<i>Related to sodium and water retention secondary to elevated cortisol levels</i>)	Overload: Edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values	Record daily weight and monitor trends; record accurate intake and output; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit, sodium); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; assess and trend heart rate and blood pressure; assess for symptoms of fluid overload such as Jugular Venous Distention (JVD), shortness of breath, dyspnea, crackles; encourage low-sodium diet; administer prescribed diuretic; administer prescribed antihypertensive; elevate feet when sitting; monitor oxygenation with pulse oximetry
Injury risk (<i>Related to poor wound healing; decreased bone density; capillary fragility</i>)	Easy bruising; blood in stool; skin breakdown; fracture; poor wound healing	Assess for bruising; assess stool for occult blood; assess for skin breakdown; assess wound for healing progress; facilitate ordered bone density screening

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for the amount of cortisol in the blood.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, as well as results of

previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that

there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Drugs that enhance steroid metabolism may be withheld by medical direction prior to metyrapone stimulation testing.
- ▶ Instruct the patient to minimize stress to avoid raising cortisol levels.

INTRATEST:

Potential Complications:

Adverse reactions to metyrapone include nausea and vomiting (N/V), abdominal pain, headache, dizziness, sedation, allergic rash, decreased white blood cell count, or bone marrow depression. Monitor the patient for hypotension, rapid and weak pulse, rapid respiratory rate, pallor, and extreme weakness that may indicate the patient is in acute adrenocortical insufficiency (Addisonian crisis). Other signs and symptoms include cardiac arrhythmias, hypotension, dehydration, anxiety, confusion, impairment of consciousness, N/V, epigastric pain, diarrhea, hyponatremia, and hyperkalemia.

- ▶ Have emergency equipment readily available.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Collect specimen between 6 and 8 a.m., when cortisol levels are highest.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and offer support.
- ▶ Observe/assess the patient who has been administered metyrapone for signs and symptoms of an acute adrenal (Addisonian) crisis which may include abdominal pain, nausea, vomiting, hypotension, tachycardia, tachypnea, dehydration, excessively increased perspiration of the face and hands, sudden and significant fatigue or weakness, confusion, loss of consciousness, shock, coma. Potential interventions include immediate corticosteroid replacement (IV or IM), airway protection and maintenance, administration of dextrose for hypoglycemia, correction of electrolyte imbalance, and rehydration with IV fluids.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Assess the patient with regard to the effects of abnormal cortisol levels, and monitor blood glucose levels to identify

hyperglycemia associated with elevated cortisol.

- ▶ Educate the patient regarding access to counseling services.
- ▶ Provide contact information, if desired, for the Cushing's Support and Research Foundation (www.csrf.net).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Recognize anxiety related to test results and answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach patient to use devices that will decrease injury risk such as soft toothbrush or electric rather than steel blade razor.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that precautions should be taken with activity to prevent injury
- ▶ States understanding of reporting difficulty breathing promptly for timely intervention and prevention of respiratory distress

Skills

- ▶ Identifies and selects a diet that is high in fiber and drinks plenty of fluids to prevent constipation and potential GI bleed
- ▶ Demonstrates performance of good personal hygiene including moisturizing of skin to prevent breakdown

Attitude

- ▶ Complies with HCP's recommendation to increase the intake of calcium and vitamin D
- ▶ Complies with the request to maintain good personal hygiene including frequent hand hygiene

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH and challenge tests, angiography adrenal, chloride, CT abdomen, CT pituitary, DHEA, glucagon, glucose, glucose tolerance test, growth hormone, insulin, MRI abdomen, MRI pituitary, renin, sodium, testosterone, and US abdomen.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

C-Peptide

SYNONYM/ACRONYM: Connecting peptide insulin, insulin C-peptide, proinsulin C-peptide.

COMMON USE: To evaluate hypoglycemia, assess beta cell function, and distinguish between type 1 and type 2 diabetes.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Immunochemiluminometric assay, ICMA)

Age	Conventional Units	SI Units (Conventional Units × 0.333)
9 yr	0–3.3 ng/mL	0–1.1 nmol/L
10–16 yr	0.4–3.3 ng/mL	0.1–1.1 nmol/L
Greater than 16 yr	0.8–3.5 ng/mL	0.3–1.2 nmol/L
1 hr response to glucose	2.3–11.8 ng/mL	0.8–3.9 nmol/L

DESCRIPTION: C-peptide is a biologically inactive peptide formed when beta cells of the pancreas convert proinsulin to insulin. Most of C-peptide is excreted by the kidneys. C-peptide levels usually correlate with insulin levels and provide a reliable indication of how well the pancreatic beta cells secrete insulin. Release of C-peptide is not affected by exogenous insulin administration. C-peptide values double after stimulation with glucose or glucagon, and measurement of C-peptide levels are very useful in the evaluation of hypoglycemia. An insulin/C-peptide ratio less than 1 indicates endogenous insulin secretion, whereas a ratio greater than 1 indicates an excess of exogenous insulin. An elevated C-peptide level in the presence of plasma glucose less than 40 mg/dL supports a diagnosis of pancreatic islet cell tumor.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of insulinoma: serum levels of insulin and C-peptide are elevated.
- Detect suspected factitious cause of hypoglycemia (excessive insulin administration): an increase in blood insulin from injection does not increase C-peptide levels.
- Determine beta cell function when insulin antibodies preclude accurate measurement of serum insulin production.
- Distinguish between insulin-dependent (type 1) and non-insulin-dependent (type 2) diabetes (with C-peptide-stimulating test): Patients with diabetes whose C-peptide stimulation level is greater than

18 ng/mL can be managed without insulin treatment.

- Evaluate hypoglycemia.
- Evaluate viability of pancreatic transplant.

POTENTIAL DIAGNOSIS

Increased in

- Islet cell tumor (*related to excessive endogenous insulin production*)
- Non-insulin-dependent (type 2) diabetes (*related to increased insulin production*)
- Pancreas or beta cell transplants (*related to increased insulin production*)
- Renal failure (*increase in circulating levels of C-peptide related to decreased renal excretion*)

Decreased in

- Factitious hypoglycemia (*related to decrease in blood glucose levels in response to insulin injection*)
- Insulin-dependent (type 1) diabetes (*evidenced by insufficient production of insulin by the pancreas*)
- Pancreatectomy (*evidenced by absence of the pancreas*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase C-peptide levels include beta-methasone, chloroquine, danazol, deferoxamine, ethinyl estradiol, glibenclamide, glimepiride, indapamide, oral contraceptives, piretanide, prednisone, and rifampin.
- Drugs that may decrease C-peptide levels include atenolol and calcitonin.
- C-peptide and endogenous insulin levels do not always correlate in obese patients.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for low blood sugar.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for at least 10 hr before specimen collection. Protocols may vary among facilities.
- ▶ Note that there are no fluid or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions and pretesting preparations; assure that food has been restricted for at least 10 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet as directed by the HCP.
- ▶ **Nutritional Considerations:** Abnormal C-peptide levels may be associated with diabetes. There is no "diabetic diet"; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a "Mediterranean"-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approach to

Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) with the appropriate health care professionals, particularly professionals trained in nutrition.

- ▶ Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy). Emphasize, as appropriate, that good control of glucose levels delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, if indicated, that good glycemic control delays the

onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org) or the American Heart Association (www.americanheart.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CT cardiac scoring, cortisol, creatinine, creatinine clearance, EMG, ENG, fluorescein angiography, fructose, fundus photography, glucagon, glucose, glucose tolerance tests, glycated hemoglobin, insulin, insulin antibodies, microalbumin, plethysmography, and visual fields test.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

C-Reactive Protein

SYNONYM/ACRONYM: CRP.

COMMON USE: Indicates a nonspecific inflammatory response; this highly sensitive test is used to assess risk for cardiovascular and peripheral artery disease.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Nephelometry)

High-sensitivity immunoassay**(cardiac applications)**

	Conventional Units	SI Units (Conventional Units × 10)
Low risk	Less than 1 mg/dL	Less than 10 mg/L
Average risk	1–3 mg/dL	10–30 mg/L
High risk	Greater than 10 mg/dL (after repeat testing)	Greater than 100 mg/L (after repeat testing)

Conventional Assay**Conventional Units****SI Units (Conventional Units × 10)**

Adult	0–0.8 mg/dL	0–8 mg/L
-------	-------------	----------

Values for infants are approximately half normal adult values.

DESCRIPTION: C-reactive protein (CRP) is a glycoprotein produced by the liver in response to acute inflammation. The CRP assay is a nonspecific test that determines the presence (not the cause) of inflammation; it is often ordered in conjunction with erythrocyte sedimentation rate (ESR). CRP assay is a more sensitive and rapid indicator of the presence of an inflammatory process than ESR. CRP disappears from the serum rapidly when inflammation has subsided. The inflammatory process and its association with atherosclerosis make the presence of CRP, as detected by highly sensitive CRP assays, a potential marker for coronary artery disease. It is believed that the inflammatory process may instigate the conversion of a stable plaque to a weaker one that can rupture and occlude an artery.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the differential diagnosis of appendicitis and acute pelvic inflammatory disease

- Assist in the differential diagnosis of Crohn's disease and ulcerative colitis
- Assist in the differential diagnosis of rheumatoid arthritis and uncomplicated systemic lupus erythematosus (SLE)
- Assist in the evaluation of coronary artery disease
- Detect the presence or exacerbation of inflammatory processes
- Monitor response to therapy for autoimmune disorders such as rheumatoid arthritis

POTENTIAL DIAGNOSIS**Increased in**

Conditions associated with an inflammatory response stimulate production of CRP.

- Acute bacterial infections
- Crohn's disease
- Inflammatory bowel disease
- Myocardial infarction (**inflammation of the coronary vessels is associated with increased CRP levels and increased risk for coronary vessel injury, which may result in distal vessel plaque occlusions**)
- Pregnancy (second half)
- Rheumatic fever
- Rheumatoid arthritis

- SLE
- Syndrome X (metabolic syndrome) (*inflammation of the coronary vessels is associated with increased CRP levels and increased risk for coronary vessel injury, which may result in distal vessel plaque occlusions*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase CRP levels include chemotherapy, interleukin-2, oral contraceptives, and pamidronate.
- Drugs that may decrease CRP levels include aurothiomalate, dexamethasone, gemfibrozil, leflunomide, methotrexate, NSAIDs, oral contraceptives (progestogen effect), penicillamine, pentopril, prednisolone, prinomide, and sulfasalazine.
- NSAIDs, salicylates, and steroids may cause false-negative results because of suppression of inflammation.
- Falsely elevated levels may occur with the presence of an intrauterine device.
- Lipemic samples that are turbid in appearance may be rejected for analysis when nephelometry is the test method.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to metabolic or endocrine dysfunction; chronic debilitating illness; cirrhosis; trauma; vectors; decreased tissue perfusion</i>)	Temperature; increased heart rate; increased blood pressure; shaking; chills; mottled skin; lethargy; fatigue; swelling; edema; pain; localized pressure; diaphoresis; night sweats; confusion; vomiting; nausea; headache	Promote good hygiene; assist with hygiene as needed; administer prescribed antibiotics, antipyretics; provide cooling measures; administer prescribed intravenous fluids; monitor vital signs and trend temperatures; encourage oral fluids; adhere to standard or universal precautions; isolate as appropriate; obtain cultures as ordered; encourage use of lightweight clothing and bedding
Fear (<i>Related to loss of control; ineffective coping; change in life expectancy; unfamiliar surroundings; illness; disease; unknown</i>)	Expression of fear; preoccupation with fear; increased tension; increased blood pressure; increased heart rate; vomiting; diarrhea; nausea; fatigue; weakness; insomnia; shortness of	Access social services; provide specific and culturally appropriate education; assist the patient and family to recognize effective coping strategies; assist the patient to acknowledge his or her fear; provide a safe environment to decrease fear; explore cultural influences that may enhance fear; utilize therapeutic touch

Problem	Signs & Symptoms	Interventions
	breath; increased respiratory rate; withdrawal; panic attacks	as appropriate to decrease fear; collaborate with social services, respiratory services, physical therapy, occupational therapy to address specific medical problems associated with fear
Tissue perfusion (<i>Related to hypovolemia; decreased hemoglobin; interrupted arterial flow; interrupted venous flow</i>)	Hypotension; dizziness; cool extremities; pallor; capillary refill greater than 3 sec in fingers and toes; weak pedal pulses; altered level of consciousness; altered sensation	Monitor blood pressure; assess for dizziness; assess extremities for skin temperature, color, warmth; assess capillary refill; assess pedal pulses; monitor for numbness, tingling, hyperesthesia, hypoesthesia; monitor for deep vein thrombosis (DVT); carefully use heat and cold on affected areas; use foot cradle to keep pressure off of affected body parts
Activity (<i>Related to inflammation; altered tissue perfusion; deconditioned state</i>)	Weakness; verbal report of fatigue; altered sleep pattern; altered blood pressure, heart rate, or respiratory rate in response to activity; oxygen desaturation with activity	Assess current level of activity and weakness; identify the patient's perception of the cause of weakness; assess the need for the use of assistive devices; observe and document the patient's tolerance to activity; provide ordered oxygen; limit energy expenditure to necessary activities

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for inflammation.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex. The patient may complain of pain related to the inflammatory process in connective or other tissues.
- ▶ Obtain a history of the patient's cardiovascular and immune systems, symptoms, and results of previously

performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and assist with pain management as ordered. Ensure the patient receives a referral for physical therapy as appropriate. Explain the importance of maintaining an upright position when standing, sitting, and walking to maximize joint function and mobility. Discuss the proper mix of rest and activity and the importance of taking regular rest periods throughout the day to prevent exhaustion.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient to use pillows to properly position himself or herself and provide relief to stressed joints.
- ▶ Explain the signs and symptoms of infection to the patient and family including what to report and when to report concerns.
- ▶ Teach the appropriate use of environmental aids to facilitate safe activity such as lowering and raising the bed, moving from bed to chair, and using assistive devices in the bathroom.

Expected Patient Outcomes:

Knowledge

- ▶ Formulates a plan that will decrease fall risk
- ▶ Describes symptoms that may occur as a result of physical overactivity

Skills

- ▶ Accurately demonstrates how to take and record a temperature
- ▶ Proficiently demonstrates the proper use of assistive devices

Attitude

- ▶ Complies with the request to obtain appropriate immunizations
- ▶ Joins a counseling group to address ongoing anxiety and associated fears

RELATED MONOGRAPHS:

- ▶ Related tests include antiarrhythmic drugs, antibodies anticyclic citrullinated peptide, ANA, apolipoprotein A and B, AST, arthroscopy, ANP, blood gases, BMD, bone scan, BNP, calcium (blood and ionized), cholesterol (total, HDL, and LDL), CBC, CBC WBC count and differential, CT, cardiac scoring, CK and isoenzymes, echocardiography, ESR, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, MRI chest, MRI musculoskeletal, MI scan, myocardial perfusion scan, myoglobin, PET heart, potassium, procalcitonin, radiography bone, RF, synovial fluid analysis, triglycerides, and troponin.
- ▶ Refer to the Cardiovascular and Immune systems tables at the end of the book for related tests by body system.

Creatine Kinase and Isoenzymes

SYNONYM/ACRONYM: CK and isoenzymes.

COMMON USE: To monitor myocardial infarction and some disorders of the musculoskeletal system such as Duchenne's muscular dystrophy.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube. Serial specimens are highly recommended. Care must be taken to use the same type of collection container if serial measurements are to be taken.

NORMAL FINDINGS: (Method: Enzymatic for CK, electrophoresis for isoenzymes; enzyme immunoassay techniques are in common use for CK-MB)

	Conventional & SI Units
Total CK	
Newborn–1 yr	Up to 2 × adult values
Male (children and adults)	50–204 units/L
Female (children and adults)	36–160 units/L
CK Isoenzymes by Electrophoresis	
CK-BB	Absent
CK-MB	0–4%
CK-MM	96–100%
CK-MB by Immunoassay	0–3 ng/mL
CK-MB Index	0–2.5

CK = creatine kinase; CK-BB = CK isoenzyme in brain; CK-MB = CK isoenzyme in heart; CK-MM = CK isoenzyme in skeletal muscle.

The CK-MB index is the CK-MB (by immunoassay) divided by the total CK and then multiplied by 100. For example, a CK-MB by immunoassay of 25 ng/mL with a total CK of 250 units/L would have a CK-MB index of 10.

Elevations in total CK occur after exercise. Values in older adults may decline slightly related to loss of muscle mass.

DESCRIPTION: Creatine kinase (CK) is an enzyme that exists almost exclusively in skeletal muscle, heart muscle, and, in smaller amounts, in the brain and lungs. This enzyme is important for intracellular storage and release of energy. Three isoenzymes, based on primary location, have been identified by electrophoresis: brain and lungs CK-BB, cardiac CK-MB, and skeletal muscle

CK-MM. When injury to these tissues occurs, the enzymes are released into the bloodstream. Levels increase and decrease in a predictable time frame. Measuring the serum levels can help determine the extent and timing of the damage. Noting the presence of the specific isoenzyme helps determine the location of the tissue damage. Atypical forms of CK can be identified. Macro-CK,

an immunoglobulin complex of normal CK isoenzymes, has no clinical significance. Mitochondrial-CK is sometimes identified in the sera of seriously ill patients, especially those with metastatic carcinoma.

Acute myocardial infarction (MI) releases CK into the serum within the first 48 hr; values return to normal in about 3 days. The isoenzyme CK-MB appears in the first 4 to 6 hr, peaks in 24 hr, and usually returns to normal in 72 hr. Recurrent elevation of CK suggests reinfarction or extension of ischemic damage. Significant elevations of CK are expected in early phases of muscular dystrophy, even before the clinical signs and symptoms appear. CK elevation diminishes as the disease progresses and

muscle mass decreases.

Differences in total CK with age and gender relate to the fact that the predominant isoenzyme is muscular in origin. Body builders have higher values, whereas older individuals have lower values because of deterioration of muscle mass.

Serial use of the mass assay for CK-MB with serial cardiac troponin I, myoglobin, and serial electrocardiograms in the assessment of MI has largely replaced the use of CK isoenzyme assay by electrophoresis. CK-MB mass assays are more sensitive and rapid than electrophoresis. Studies have demonstrated a high positive predictive value for acute MI when the CK-MB (by immunoassay) is greater than 10 ng/mL with a relative CK-MB index greater than 3.

Timing for Appearance and Resolution of Serum/Plasma Cardiac Markers in Acute MI

Cardiac Marker	Appearance (hr)	Peak (hr)	Resolution (days)
AST	6–8	24–48	3–4
CK (total)	4–6	24	2–3
CK-MB	4–6	15–20	2–3
LDH	12	24–48	10–14
Myoglobin	1–3	4–12	1
Troponin I	2–6	15–20	5–7

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of acute MI and evaluate cardiac ischemia (CK-MB)
- Detect musculoskeletal disorders that do not have a neurological basis, such as dermatomyositis or Duchenne's muscular dystrophy (CK-MM)

- Determine the success of coronary artery reperfusion after streptokinase infusion or percutaneous transluminal angioplasty, as evidenced by a decrease in CK-MB

POTENTIAL DIAGNOSIS

Increased in

CK is released from any damaged cell in which it is stored, so conditions that affect the brain, heart, or

skeletal muscle and cause cellular destruction demonstrate elevated CK levels and correlating isoenzyme source CK-BB, CK-MB, CK-MM.

- Alcoholism (*CK-MM*)
- Brain infarction (extensive) (*CK-BB*)
- Congestive heart failure (*CK-MB*)
- Delirium tremens (*CK-MM*)
- Dermatomyositis (*CK-MM*)
- Head injury (*CK-BB*)
- Hypothyroidism (*CK-MM related to metabolic effect on and damage to skeletal muscle tissue*)
- Hypoxic shock (*CK-MM related to muscle damage from lack of oxygen*)
- Gastrointestinal (GI) tract infarction (*CK-MM*)
- Loss of blood supply to any muscle (*CK-MM*)
- Malignant hyperthermia (*CK-MM related to skeletal muscle injury*)
- MI (*CK-MB*)
- Muscular dystrophies (*CK-MM*)
- Myocarditis (*CK-MB*)
- Neoplasms of the prostate, bladder, and GI tract (*CK-MM*)
- Polymyositis (*CK-MM*)

- Pregnancy; during labor (*CK-MM*)
- Prolonged hypothermia (*CK-MM*)
- Pulmonary edema (*CK-MM*)
- Pulmonary embolism (*CK-MM*)
- Reye's syndrome (*CK-BB*)
- Rhabdomyolysis (*CK-MM*)
- Surgery (*CK-MM*)
- Tachycardia (*CK-MB*)
- Tetanus (*CK-MM related to muscle injury from injection*)
- Trauma (*CK-MM*)

Decreased in

- Small stature (*related to lower muscle mass than average stature*)
- Sedentary lifestyle (*related to decreased muscle mass*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase total CK levels include any intramuscularly injected preparations because of tissue trauma caused by injection.
- Drugs that may decrease total CK levels include dantrolene and statins.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Coping (<i>Related to a feeling of threat; inadequate support system; inadequate problem-solving ability; disease process; poor self-confidence</i>)	Inability to cope with the situation; inability to make decisions; inability to ask for help; fatigue; sleep disturbance; lack of confidence; inappropriate self-defense strategies	Assess for specific stressors that alter coping; identify the patient's perception of stressors; assess for use of positive coping mechanisms; provide opportunities to express fear and anxiety in a safe, nonjudgmental environment; avoid false reassurance; convey acceptance and understanding;

(table continues on page 628)

Problem	Signs & Symptoms	Interventions
<p>Sleep (<i>Related to perceived wellness and diagnosis; fear; anxiety; inadequate coping; medication side effect</i>)</p>	<p>Report of lack of sleep or rest; fatigue; decreased energy; restlessness; decreased level of concentration; irritability; listlessness; lethargy; malaise; daytime drowsiness; confusion</p>	<p>encourage patient to identify his or her own strengths; assist the patient to accurately evaluate current situation; reduce environmental stimuli that could be misunderstood as threatening; provide a safe outlet for personal feelings; use relaxation techniques; administer prescribed medication</p> <p>Avoid loud noises; decrease lighting to a preferred restful level; administer prescribed medication; minimize interruptions; provide single-patient room if possible, if not possible a compatible roommate; assist the patient to identify the cause of his or her fear that results in insomnia; facilitate as much as possible the patient's normal bedtime routine; limit daytime sleeping; collaborate with physician to revise medications that may be causing sleeplessness</p>
<p>Cardiac output (<i>Related to prolonged myocardial ischemia; acute myocardial infarction; reduced cardiac muscle contractility; rupture papillary muscle; mitral insufficiency</i>)</p>	<p>Weak peripheral pulses; slow capillary refill; decreased urinary output; cool, clammy skin; tachypnea; dyspnea; altered level of consciousness; abnormal heart sounds; fatigue; hypoxia; loud holosystolic murmur; EKG changes; increased Jugular Venous Distention (JVD)</p>	<p>Assess peripheral pulses and capillary refill; monitor blood pressure and check for orthostatic changes; assess respiratory rate, breath sounds, and orthopnea; assess skin color and temperature; assess level of consciousness; monitor urinary output; use pulse oximetry to monitor oxygenation; monitor EKG; administer ordered inotropic and</p>

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to myocardial ischemia; myocardial infarction</i>)	Reports of chest pain; new onset of angina; shortness of breath; pallor; weakness; diaphoresis; palpitations; nausea; vomiting; epigastric pain or discomfort; increased blood pressure; increased heart rate	peripheral vasodilator medications, nitrates; provide oxygen administration Assess pain characteristics, squeezing pressure, location in substernal back, neck, or jaw; assess pain duration and onset (minimal exertion, sleep, or rest); identify pain modalities that have relieved pain in the past; monitor cardiac biomarkers (CK-MB, troponin, myoglobin); collaborate with ancillary departments to complete ordered echocardiography, exercise stress testing, pharmacological stress testing; administer prescribed pain medication; monitor and trend vital signs; administer prescribed oxygen; administer prescribed anticoagulants, antiplatelets, beta blockers, calcium channel blockers, angiotensin-converting enzyme (ACE) inhibitors, Angiotensin II receptor blockers (ARBs), thrombolytic agents

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for heart muscle cell damage.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that a series of

samples will be required. (Samples at time of admission and 2 to 4 hr, 6 to 8 hr, and 12 hr after admission are the minimal recommendations. Protocols may vary among facilities. Additional samples may be requested.) Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased CK levels may be associated with coronary artery disease (CAD). Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other

lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

- Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- Discuss the implications of abnormal test results on the patient's lifestyle.
- Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Educate the patient regarding access to counseling services.
- Provide contact information, if desired, for the AHA (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Teach the patient and family the importance of adequate rest in relation to their overall health.
- Discuss with the patient and family factors that can interfere with adequate rest such as fear or anxiety.

Expected Patient Outcomes:**Knowledge**

- Acquires understanding that irritability and mood changes are common with sleep deprivation

- Recognizes that there are safe medications available that can be used to enhance sleep

Skills

- Identifies measures that will increase the ability to obtain sleep or rest
- Identifies nighttime foods or drinks that interfere with sleep

Attitude

- Complies with the recommendation to limit daytime sleeping in order to enhance nighttime rest
- Complies with the recommendation to take prescribed medication to enhance sleep if necessary

RELATED MONOGRAPHS:

- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BNP, calcium (blood and ionized), cholesterol (total, HDL and LDL), CRP, CT cardiac scoring, echocardiography, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MRI venography, MI scan, myocardial perfusion scan, myoglobin, pericardial fluid, PET heart, potassium, triglycerides, and troponin.
- Refer to the Cardiovascular and Musculoskeletal systems tables at the end of the book for related tests by body system.

Creatinine, Blood

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess kidney function found in acute and chronic renal failure, related to drug reaction and disease such as diabetes.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 88.4)
Newborn	0.31–1.21 mg/dL	27–107 micromol/L
Infant	0.31–0.71 mg/dL	27–63 micromol/L
1–5 yr	0.31–0.51 mg/dL	27–45 micromol/L
6–10 yr	0.51–0.81 mg/dL	45–72 micromol/L
Adult male	0.61–1.21 mg/dL	54–107 micromol/L
Adult female	0.51–1.11 mg/dL	45–98 micromol/L

Values in older adults remain relatively stable after a period of decline related to loss of muscle mass during the transition from adult to older adult.

The National Kidney Foundation recommends the use of two decimal places in reporting serum creatinine for use in calculating estimated glomerular filtration rate.

DESCRIPTION: Creatine resides almost exclusively in skeletal muscle, where it participates in energy-requiring metabolic reactions. A small amount of creatine is irreversibly converted to creatinine by the liver, which then circulates to the kidneys and is excreted. The amount of creatinine generated in an individual is proportional to the mass of skeletal muscle present and remains fairly constant throughout the lifespan; its consistency in production and clearance is the reason that creatinine is used as an indicator of renal function. Creatinine values normally decrease with age owing to diminishing muscle mass. Conditions involving degenerative muscle wasting or massive muscle trauma from a crushing injury will also result in decreased creatinine levels. Blood urea nitrogen (BUN) is often ordered with creatinine for comparison. The BUN/creatinine ratio is also a useful indicator of kidney disease. The ratio should be between 10:1 and 20:1. The creatinine clearance test measures a blood sample and a urine sample to determine the rate at which

the kidneys are clearing creatinine from the blood; this reflects the glomerular filtration rate, or GFR (see monograph titled “Creatinine, Urine, and Creatinine Clearance, Urine”).

Chronic kidney disease (CKD) is a significant health concern worldwide. An international effort to standardize methods to identify and monitor CKD has been undertaken by the National Kidney Disease Education Program (NKDEP), the International Confederation of Clinical Chemistry and Laboratory Medicine, and the European Communities Confederation of Clinical Chemistry. International efforts have resulted in development of an isotope dilution mass spectrometry (IDMS) reference method for standardized measurement of creatinine. The National Kidney Foundation (NKF) has recommended use of an equation to estimate glomerular filtration rate (eGFR). The equation is based on factors identified in the NKF Modification of Diet in Renal Disease (MDRD) study. The equation includes four factors: serum or plasma creatinine value, age (in years), gender, and race. The

equation is valid only for patients between the ages of 18 and 70. A correction factor is incorporated in the equation if the patient is African American because CKD is more prevalent in African Americans; results are approximately 20% higher. It is very important to know whether the creatinine has been measured using an IDMS traceable test method because the values will differ; results are lower. The equations have not been validated for pregnant women (GFR is significantly increased in pregnancy); patients younger than 18 or older than 70; patients with serious comorbidities; or patients with extremes in body size, muscle mass, or nutritional status. eGFR calculators can be found at the National Kidney Disease Education Program (www.nkdep.nih.gov/professionals/gfr_calculators/index.htm).

Cystatin C, also known as cystatin 3 and CST3, is now recognized as a useful marker for kidney damage and monitor of function in transplanted kidneys. It is a low molecular weight molecule belonging in the family of proteinase inhibitors. Cystatin C is produced by all nucleated cells in the body and is freely filtered by the glomerular membrane in the kidney. It is not secreted by the kidney tubules and although a small amount is reabsorbed by the kidney tubules, it is metabolized in the tubules and does not re-enter circulation. Therefore, its serum concentration is directly proportional to kidney function. It is believed to be a better marker of kidney function than creatinine because levels are independent of weight and height, diet, muscle mass, age, and sex.

Normal values for individuals age 1–50 years are 0.56–0.9 mg/L and 0.58–1.08 mg/L for age 50 years and older.

This procedure is contraindicated for: N/A

INDICATIONS

- Assess a known or suspected disorder involving muscles in the absence of renal disease
- Evaluate known or suspected impairment of renal function

POTENTIAL DIAGNOSIS

Increased in

- Acromegaly (*related to increased muscle mass*)
- Congestive heart failure (*related to decreased renal blood flow*)
- Dehydration (*related to hemoconcentration*)
- Gigantism (*related to increased muscle mass*)
- Poliomyelitis (*related to increased release from damaged muscle*)
- Pregnancy induced hypertension (*related to reduced GFR and decreased urinary excretion*)
- Renal calculi (*related to decreased renal excretion due to obstruction*)
- Renal disease, acute and chronic renal failure (*related to decreased urinary excretion*)
- Rhabdomyolysis (*related to increased release from damaged muscle*)
- Shock (*related to increased release from damaged muscle*)

Decreased in

- Decreased muscle mass (*related to debilitating disease or increasing age*)
- Hyperthyroidism (*related to increased GFR*)
- Inadequate protein intake (*related to decreased muscle mass*)

- Liver disease (severe) (*related to fluid retention*)
- Muscular dystrophy (*related to decreased muscle mass*)
- Pregnancy (*related to increased GFR and renal clearance*)
- Small stature (*related to decreased muscle mass*)

CRITICAL FINDINGS

Adults

Potential critical value is greater than 7.4 mg/dL (SI: 654.2 micromol/L) (nondialysis patient).

Children

Potential critical value is greater than 3.8 mg/dL (SI: 336 micromol/L) (nondialysis patient).

Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Chronic renal insufficiency is identified by creatinine levels between 1.5 and 3 mg/dL; chronic renal failure is present at levels greater than 3 mg/dL.

Possible interventions may include renal or peritoneal dialysis and organ transplant, but early discovery of the cause of elevated creatinine levels might avoid such drastic interventions.

INTERFERING FACTORS

- Drugs and substances that may increase creatinine levels include acebutolol, acetaminophen (overdose), acetylsalicylic acid, aldatense, amikacin, amiodarone, amphotericin B, arginine, arsenicals, ascorbic acid, asparaginase, barbiturates, capreomycin, captopril, carbutamide, carvedilol, cephalothin, chlorthalidone, cimetidine, cisplatin, clofibrate, colistin, corn oil (Lipomul), cyclosporine, dextran, doxycycline, enalapril, ethylene glycol, gentamicin, indomethacin, ipodate, kanamycin, levodopa, mannitol, methicillin, methoxyflurane, mitomycin, neomycin, netilmicin, nitrofurantoin, NSAIDs, oxyphenbutazone, paromomycin, penicillin, pentamidine, phosphorus, plicamycin, radiographic agents, semustine, streptokinase, streptozocin, tetracycline, thiazides, tobramycin, triamterene, vancomycin, vasopressin, viomycin, and vitamin D.
- Drugs that may decrease creatinine levels include citrates, dopamine, ibuprofen, and lisinopril.
- High blood levels of bilirubin and glucose can cause false decreases in creatinine.
- A diet high in meat can cause increased creatinine levels.
- Ketosis can cause a significant increase in creatinine.
- Hemolyzed specimens are unsuitable for analysis.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fluid volume <i>(Related to excess fluid and sodium intake; compromised renal function)</i>	Excess: edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values; distended neck veins; tachycardia; restlessness	Record daily weight and monitor trends; ensure accurate intake and output; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit, sodium); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; assess and trend heart rate and blood pressure; assess for symptoms of fluid overload such as Jugular Venous Distension (JVD), shortness of breath, dyspnea, crackles; ensure low-sodium diet; administer prescribed diuretic; administer prescribed antihypertensive; elevate feet when sitting; monitor oxygenation with pulse oximetry; administer oxygen as appropriate; elevate the head of the bed; administer prescribed antihypertensives
Cardiac output <i>(Related to excess fluid volume; pericarditis; electrolyte imbalance; toxin accumulation)</i>	Weak peripheral pulses; slow capillary refill; decreased urinary output; cool clammy skin; tachypnea; dyspnea; altered level of consciousness; abnormal heart sounds; fatigue; hypoxia; loud holosystolic murmur; EKG changes; increased JVD	Assess peripheral pulses and capillary refill; monitor blood pressure and check for orthostatic changes; assess respiratory rate, breath sounds, and orthopnea; assess skin color and temperature; assess level of consciousness; monitor urinary output; use pulse oximetry to monitor oxygenation; monitor EKG; administer ordered inotropic and peripheral vasodilator medications, nitrates; provide oxygen administration; administer as prescribed (sodium bicarbonate, glucose, insulin drip, potassium excretion resin, calcium salt)

(table continues on page 636)

Problem	Signs & Symptoms	Interventions
Protection <i>(Anemia-related to bone marrow suppression secondary to renal insufficiency [erythropoietic]; red cell destruction secondary to altered plasma environment; nutritional deficiency; decreased and defective platelets; blood loss; ineffective clotting)</i>	Pallor; fatigue; weakness; shortness of breath; anxiety; easy bruising; increased clotting time	Assess for symptoms of anemia (fatigue, pallor, decreased activity); observe for prolonged bleeding associated with ineffective clotting; use pulse oximetry or arterial blood gases to assess oxygenation; administer oxygen as required; administer blood or blood products as required; administer prescribed epoetin alfa; use bleeding precautions (avoid aspirin products, avoid trauma, avoid constipation, avoid forceful nose blowing that could cause nosebleed)
Sexuality <i>(Related to amenorrhea; decreased libido; lack of ovulation; testicular atrophy; impotence; psychological impairment secondary to physical effects of renal insufficiency)</i>	Reduced sexual function; decreased sexual satisfaction; alteration in the relationship with partner	Assess perception of reported change in sexual function; assess the emotional impact of decreased libido (depression, altered self-esteem, altered personal relationships); assess for need of counseling; encourage verbalization of feelings; discuss alternative forms of intimate expression; discuss medical treatments that may improve sexual function

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing kidney function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's genitourinary and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that

specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Instruct the patient to refrain from excessive exercise for 8 hr before the test.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with activity restrictions; assure that activity has been restricted for at least 8 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased creatinine levels may be associated with kidney disease. The nutritional needs of patients with kidney disease

vary widely and are in constant flux. Anorexia, nausea, and vomiting commonly occur, prompting the need for continuous monitoring for malnutrition, especially among patients receiving long-term hemodialysis therapy.

- ▶ Recognize anxiety related to test results and be supportive of impaired activity related to fear of shortened life expectancy. Help the patient to cope with long-term implications. Recognize that anticipatory anxiety and grief related to potential lifestyle changes may be expressed when someone is faced with a chronic disorder.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services.
- ▶ Provide contact information, if desired, for the National Kidney Foundation (www.kidney.org) or the National Kidney Disease Education Program (www.nkdep.nih.gov).

Expected Patient Outcomes:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient to resume usual activity as directed by the HCP.

Knowledge

- ▶ States causes of decreased libido
- ▶ Identifies causes of anemia

Skills

- ▶ Demonstrates proficiency in taking prescribed medication accurately
- ▶ Demonstrates proficiency in selecting activities that decrease bleeding risk

Attitude

- Discusses the efficacy of counseling to repair personal relationship secondary to intimacy concerns
- States approach to care planning for sexual dysfunction is realistic

RELATED MONOGRAPHS:

- Related tests include anion gap, antimicrobial drugs, ANF, BNP, biopsy muscle, blood gases, BUN, calcium, calculus kidney stone panel, CT abdomen, CT renal, CK and isoenzymes, creatinine

clearance, cystoscopy, echocardiography, echocardiography transesophageal, electrolytes, EMG, ENG, glucagon, glucose, glycolated hemoglobin, insulin, IVP, KUB studies, lung perfusion scan, MRI venography, microalbumin, osmolality, phosphorus, renogram, retrograde ureteropyelography, TSH, thyroxine, US abdomen, uric acid, and UA.

- Refer to the Genitourinary and Musculoskeletal systems tables at the end of the book for related tests by body system.

Creatinine, Urine, and Creatinine Clearance, Urine

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess and monitor kidney function related to acute or chronic nephritis.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units
		Urine Creatinine (Conventional Units × 8.84)
2–3 yr	6–22 mg/kg/24 hr	53–194 micromol/kg/24 hr
4–18 yr	12–30 mg/kg/24 hr	106–265 micromol/kg/24 hr
Adult male	14–26 mg/kg/24 hr	124–230 micromol/kg/24 hr
Adult female	11–20 mg/kg/24 hr	97–177 micromol/kg/24 hr
		Creatinine Clearance (Conventional Units × 0.0167)
Children	70–140 mL/min/1.73 m ²	1.17–2.33 mL/s/1.73 m ²
Adult male	85–125 mL/min/1.73 m ²	1.42–2.08 mL/s/1.73 m ²
Adult female	75–115 mL/min/1.73 m ²	1.25–1.92 mL/s/1.73 m ²
For each decade after 40 yr	Decrease of 6–7 mL/min/1.73 m ²	Decrease of 0.06–0.07 mL/s/1.73 m ²

DESCRIPTION: Creatinine is the end product of creatine metabolism. Creatine resides almost exclusively in skeletal muscle, where it participates in energy-requiring metabolic reactions. In these processes, a small amount of creatine is irreversibly converted to creatinine, which then circulates to the kidneys and is excreted. The amount of creatinine generated in an individual is proportional to the mass of skeletal muscle present and remains fairly constant, unless there is massive muscle damage resulting from crushing injury or degenerative muscle disease. Creatinine values decrease with advancing age owing to diminishing muscle mass. Although the measurement of urine creatinine is an effective indicator of renal function, the creatinine clearance test is more precise. The creatinine clearance test measures a blood sample and a urine sample to determine the rate at which the kidneys are clearing creatinine from the blood; this reflects the glomerular filtration rate (GFR) and is based on an estimate of body surface.

Chronic kidney disease (CKD) is a significant health concern worldwide. An international effort to standardize methods to identify and monitor CKD has been undertaken by the National Kidney Disease Education Program (NKDEP), the International Confederation of Clinical Chemistry and Laboratory Medicine, and the European Communities Confederation of Clinical Chemistry. International efforts have resulted in development of an isotope dilution mass spectrometry (IDMS) reference method for standardized

measurement of creatinine. The National Kidney Foundation (NKF) has recommended use of an equation to estimate glomerular filtration rate (eGFR). The equation is based on factors identified in the NKF Modification of Diet in Renal Disease (MDRD) study. The equation includes four factors: serum or plasma creatinine value, age in years, gender, and race. The equation is valid only for patients between the ages of 18 and 70. A correction factor is incorporated in the equation if the patient is African American because CKD is more prevalent in African Americans; results are approximately 20% higher. It is very important to know whether the creatinine has been measured using an IDMS traceable test method because the values will differ; results are lower. The equations have not been validated for pregnant women (GFR is significantly increased in pregnancy); patients younger than 18 or older than 70; patients with serious comorbidities; or patients with extremes in body size, muscle mass, or nutritional status. eGFR calculators can be found at the NKDEP (www.nkdep.nih.gov/professionals/gfr_calculators/index.htm).

- **Creatinine clearance can be estimated from a blood creatinine level:**

$$\text{Creatinine clearance} = [1.2 \times (140 - \text{age in years}) \times (\text{weight in kg})] / \text{blood creatinine level.}$$

The result is multiplied by 0.85 if the patient is female; the result is multiplied by 1.18 if the patient is African American.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine the extent of nephron damage in known renal disease (at least 50% of functioning nephrons must be lost before values are decreased)
- Determine renal function before administering nephrotoxic drugs
- Evaluate accuracy of a 24-hr urine collection based on the constant level of creatinine excretion
- Evaluate glomerular function
- Monitor effectiveness of treatment in renal disease

POTENTIAL DIAGNOSIS

Increased in

- Acromegaly (*related to increased muscle mass*)
- Carnivorous diets (*related to increased intake of creatine, which is metabolized to creatinine and excreted by the kidneys*)
- Exercise (*related to muscle damage; increased renal blood flow*)
- Gigantism (*related to increased muscle mass*)

Decreased in

Conditions that decrease GFR, impair kidney function, or reduce renal blood flow will decrease renal excretion of creatinine

- Acute or chronic glomerulonephritis
- Chronic bilateral pyelonephritis
- Leukemia
- Muscle wasting diseases (*related to abnormal creatinine production; decreased production reflected in decreased excretion*)
- Paralysis (*related to abnormal creatinine production; decreased production reflected in decreased excretion*)

- Polycystic kidney disease
- Pregnancy induced hypertension (*related to reduced GFR*)
- Shock
- Urinary tract obstruction (e.g., from calculi)
- Vegetarian diets (*evidenced by diets that exclude intake of animal muscle, the creatine source metabolized to creatinine and excreted by the kidneys*)

CRITICAL FINDINGS

- Degree of impairment:
 Borderline: 62.5–80 mL/min/1.73 m²
 (SI: 1–1.3 mL/s/1.73 m²)
 Slight: 52–62.5 mL/min/1.73 m²
 (SI: 0.9–1 mL/s/1.73 m²)
 Mild: 42–52 mL/min/1.73 m²
 (SI: 0.7–0.9 mL/s/1.73 m²)
 Moderate: 28–42 mL/min/1.73 m²
 (SI: 0.5–0.7 mL/s/1.73 m²)
 Marked: Less than 28 mL/min/1.73 m²
 (SI: Less than 0.5 mL/s/1.73 m²)

Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of

notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Drugs that may increase urine creatinine levels include ascorbic acid, cefoxitin, cephalothin, corticosteroids, fluoxymesterone, levodopa, methandrostenolone, methotrexate, methyldopa, nitrofurans (including nitrofurazone), oxymetholone, phenolphthalein, and prednisone.
- Drugs that may increase urine creatinine clearance include enalapril, oral contraceptives, prednisone, and ramipril.
- Drugs that may decrease urine creatinine levels include anabolic steroids, androgens, captopril, and thiazides.
- Drugs that may decrease the urine creatinine clearance include acetylsalicylic acid, amphotericin B, carbenoxolone, chlorthalidone, cimetidine, cisplatin, cyclosporine, guancidine, ibuprofen, indomethacin, mitomycin, oxyphenbutazone, probenecid (coadministered with digoxin), puromycin, and thiazides.
- Excessive ketones in urine may cause falsely decreased values.
- Failure to follow proper technique in collecting 24-hr specimen may invalidate test results.
- Failure to refrigerate specimen throughout urine collection period allows decomposition of creatinine, causing falsely decreased values.
- Consumption of large amounts of meat, excessive exercise, and stress should be avoided for 24 hr before the test. Protocols may vary among facilities.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing kidney function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain to the patient that there should be no discomfort during the urine collection procedure. Inform the patient that a blood sample for creatinine will be required on the day urine collection begins or at some point during the 24 hr collection period (see monograph titled "Creatinine, Blood" for additional information).
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

- ▶ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.
- ▶ Note that there are no fluid or medication restrictions unless by medical direction.
- ▶ Instruct the patient to refrain from eating meat during the test. Protocols may vary among facilities.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary and activity restrictions for 24 hr prior to the procedure; assure that ingestion of meat has been restricted during the test.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture as appropriate.

Random Specimen (collect in early morning) Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Pediatric Urine Collector

- ▶ Put on gloves. Appropriately cleanse the genital area and allow the area to dry. Remove the covering over the

adhesive strips on the collector bag and apply over the genital area. Diaper the child. When specimen is obtained, place the entire collection bag in a sterile urine container.

Indwelling Catheter

- ▶ Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Urinary Catheterization

- ▶ Place female patient in lithotomy position or male patient in supine position. Using sterile technique, open the straight urinary catheterization kit and perform urinary catheterization. Place the retained urine in a sterile specimen container.

Suprapubic Aspiration

- ▶ Place the patient in a supine position. Cleanse the area with antiseptic and drape with sterile drapes. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container.
- ▶ Do not collect urine from the pouch from the patient with a urinary diversion (e.g., ileal conduit). Instead, perform catheterization through the stoma.

Timed Specimen

- ▶ Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- ▶ Begin the test between 6 and 8 a.m. if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next

morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.

- ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same time the collection was begun.
- ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- ▶ Include on the collection container's label the amount of urine, test start and stop times, and any foods or medications that can affect test results.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, medications, and activity, as directed by the HCP.
- ▶ Recognize anxiety related to test results and be supportive of impaired activity related to fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as

appropriate. Educate the patient regarding access to counseling services. Help the patient to cope with long-term implications. Recognize that anticipatory anxiety and grief related to potential lifestyle changes may be expressed when someone is faced with a chronic disorder. Provide contact information, if desired, for the NKF (www.kidney.org) or the NKDEP (www.nkdep.nih.gov).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include anion gap, antimicrobial drugs, antibodies anti-glomerular basement membrane, ANF, biopsy kidney, biopsy muscle, blood gases, BNP, BUN, calcium, calculus kidney stone analysis, C4, CT abdomen, CT renal, CK and isoenzymes, creatinine, culture urine, cytology urine, cystoscopy, echocardiography, echocardiography transesophageal, electrolytes, EMG, ENG, EPO, gallium scan, glucagon, glucose, haptoglobin, insulin, IVP, KUB studies, lung perfusion scan, microalbumin, osmolality, phosphorus, renogram, retrograde ureteropyelography, TSH, thyroxine, US kidney, uric acid, and UA.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Cryoglobulin

SYNONYM/ACRONYM: Cryo.

COMMON USE: To assist in identifying the presence of certain immunological disorders such as Reynaud's phenomenon.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Visual observation for changes in appearance)
Negative.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in
Cryoglobulins are present in varying degrees in associated conditions.

Type I cryoglobulin (monoclonal)

- Chronic lymphocytic leukemia
- Lymphoma
- Multiple myeloma

Type II cryoglobulin (mixtures of monoclonal immunoglobulin [Ig] M and polyclonal IgG)

- Autoimmune hepatitis
- Rheumatoid arthritis
- Sjögren's syndrome

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

- Waldenström's macroglobulinemia

Type III cryoglobulin (mixtures of polyclonal IgM and IgG)

- Acute poststreptococcal glomerulonephritis
- Chronic infection (especially hepatitis C)
- Cirrhosis
- Endocarditis
- Infectious mononucleosis
- Polymyalgia rheumatica
- Rheumatoid arthritis
- Sarcoidosis
- Systemic lupus erythematosus

Decreased in: N/A

CRITICAL FINDINGS: N/A

Culture and Smear, Mycobacteria

SYNONYM/ACRONYM: Acid-fast bacilli (AFB) culture and smear, tuberculosis (TB) culture and smear, *Mycobacterium* culture and smear.

COMMON USE: To assist in the diagnosis of tuberculosis.

SPECIMEN: Sputum (5 to 10 mL), bronchopulmonary lavage, tissue, material from fine-needle aspiration, bone marrow, cerebrospinal fluid (CSF), gastric aspiration, urine, and stool.

NORMAL FINDINGS: (Method: Culture on selected media, microscopic examination of sputum by acid-fast or auramine-rhodamine fluorochrome stain) Rapid methods include: chemiluminescent-labeled DNA probes that target ribosomal RNA of the *Mycobacterium* radiometric carbon dioxide detection from ^{14}C -labeled media, polymerase chain reaction/amplification techniques.

Culture: No growth

Smear: Negative for AFB

Rapid Testing Method: *Mycobacterium*

DESCRIPTION: A culture and smear test is used primarily to detect *Mycobacterium tuberculosis*, which is a tubercular bacillus. The cell wall of this mycobacterium contains complex lipids and waxes that do not take up ordinary stains. Cells that resist decolorization by acid alcohol are termed *acid-fast*. There are only a few groups of acid-fast bacilli (AFB); this characteristic is helpful in rapid identification so that therapy can be initiated in a timely manner. Smears may be negative 50% of the time even though the culture develops positive growth 3 to 8 wk later. AFB cultures are used to confirm positive and negative AFB smears.

M. tuberculosis grows in culture slowly. Automated liquid culture systems, such as the Bactec and MGIT (Becton Dickinson and Company, 1 Becton Drive, Franklin Lakes, NJ, 07417), have a turnaround time of approximately 10 days. Results of tests by polymerase chain reaction culture methods are available in 24 to 72 hr. The QuantiFERON-TB Gold (QFT-G), QuantiFERON-TB Gold In-Tube (QFT-GIT), and T-SPOT interferon release blood tests are approved by the U.S. Food and Drug Administration for all applications in which the TB skin test is used. The blood test is a procedure in which a sample of whole blood from the patient is incubated with a reagent cocktail

of peptides known to be present in individuals infected by *Mycobacterium tuberculosis* but not found in the blood of previously vaccinated individuals or individuals who do not have the disease. The blood test offers the advantage of eliminating many of the false reactions encountered with skin testing, only a single patient visit is required, and results can be available within 24 hr. The blood tests and skin tests are approved as indirect tests for *Mycobacterium tuberculosis*, and the Centers for Disease Control and Prevention (CDC) recommends their use in conjunction with risk assessment, chest x-ray, and other appropriate medical and diagnostic evaluations. Detailed information is found in the monograph titled "Tuberculosis: Skin and Blood Tests."

M. tuberculosis is transmitted via the airborne route to the lungs. It causes areas of granulomatous inflammation, cough, fever, and hemoptysis. It can remain dormant in the lungs for long periods. The incidence of tuberculosis has increased since the late 1980s in depressed inner-city areas, among prison populations, and among HIV-positive patients. Of great concern is the increase in antibiotic-resistant strains. HIV-positive patients often become ill from concomitant

infections caused by *M. tuberculosis* and *Mycobacterium avium intracellulare*. *M. avium intracellulare* is acquired via the gastrointestinal tract through ingestion of contaminated food or water. The organism's waxy cell wall protects it from acids in the human digestive tract. Isolation of mycobacteria in the stool does not mean the patient has tuberculosis of the intestines because mycobacteria in stool are most often present in sputum that has been swallowed.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of mycobacteriosis.
- Assist in the diagnosis of suspected pulmonary tuberculosis secondary to AIDS.
- Assist in the differentiation of tuberculosis from carcinoma or bronchiectasis.
- Investigate suspected pulmonary tuberculosis.
- Monitor the response to treatment for pulmonary tuberculosis.

POTENTIAL DIAGNOSIS

Identified Organism	Primary Specimen Source	Condition
<i>Mycobacterium avium intracellulare</i>	CSF, lymph nodes, semen, sputum, urine	Opportunistic pulmonary infection
<i>M. fortuitum</i>	Bone, body fluid, sputum, surgical wound, tissue	Opportunistic infection (usually pulmonary)
<i>M. leprae</i>	CSF, skin scrapings, lymph nodes	Hanson's disease (leprosy)
<i>M. kansasii</i>	Joint, lymph nodes, skin, sputum	Pulmonary tuberculosis
<i>M. marinum</i>	Joint	Granulomatous skin lesions
<i>M. tuberculosis</i>	CSF, gastric washing, sputum, urine	Pulmonary tuberculosis
<i>M. xenopi</i>	Sputum	Pulmonary tuberculosis

CRITICAL FINDINGS

- **Smear:** Positive for AFB
- **Rapid Testing Method:** Positive for *Mycobacterium*
- **Culture:** Growth of pathogenic bacteria

Note and immediately report to the health-care provider (HCP) positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). Lists of specific organisms may vary

among facilities; specific organisms are required to be reported to local, state, and national departments of health.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique

identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Specimen collection after initiation of treatment with antituberculosis drug therapy may result in inhibited or no growth of organisms.
- Contamination of the sterile container with organisms from an exogenous source may produce misleading results.
- Specimens received on a dry swab should be rejected: A dry swab indicates that the sample is unlikely to have been collected properly or unlikely to contain a representative quantity of significant organisms for proper evaluation.
- Inadequate or improper (e.g., saliva) samples should be rejected.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing respiratory disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex. Obtain a history of the patient's exposure to tuberculosis.

- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Review the procedure with the patient. Reassure the patient that he or she will be able to breathe during the procedure if sputum specimen is collected via suction method. Ensure that oxygen has been administered 20 to 30 min before the procedure if the specimen is to be obtained by tracheal suction. Address concerns about pain related to the procedure. Atropine is usually given before bronchoscopy examinations to reduce bronchial secretions and prevent vagally induced bradycardia. Meperidine (Demerol) or morphine may be given as a sedative. Lidocaine is sprayed in the patient's throat to reduce discomfort caused by the presence of the tube.
- ▶ Explain to the patient that the time it takes to collect a proper specimen varies according to the level of cooperation of the patient and the specimen collection site. Emphasize that sputum and saliva are not the same. Inform the patient that multiple specimens may be required at timed intervals. Inform the patient that the culture results will not be reported for 3 to 8 wk.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Bronchoscopy

- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**
- ▶ Other than antimicrobial drugs, there are no medication restrictions unless by medical direction.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have

been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

Expectorated Specimen

- ▶ Additional liquids the night before may assist in liquefying secretions during expectoration the following morning.
- ▶ Assist the patient with oral cleaning before sample collection to reduce the amount of sample contamination by organisms that normally inhabit the mouth.
- ▶ Instruct the patient not to touch the edge or inside of the container with the hands or mouth.
- ▶ Other than antimicrobial drugs, there are no medication restrictions unless by medical direction.
- ▶ There are no food or fluid restrictions unless by medical direction.

Tracheal Suctioning

- ▶ Assist in providing extra fluids, unless contraindicated, and proper humidification to decrease tenacious secretions. Inform the patient that increasing fluid intake before retiring on the night before the test aids in liquefying secretions and may make it easier to expectorate in the morning. Also explain that humidifying inspired air also helps liquefy secretions.
- ▶ Other than antimicrobial drugs, there are no medication restrictions unless by medical direction.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

bleeding, bronchial perforation, bronchospasm, infection, laryngospasm, and pneumothorax.

- ▶ Ensure that the patient has complied with dietary and medication restriction prior to the bronchoscopy procedure.
- ▶ Have patient remove dentures, contact lenses, eyeglasses, and jewelry. Notify the HCP if the patient has permanent crowns on teeth. Have the patient remove clothing and change into a gown for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available. Keep resuscitation equipment on hand in case of respiratory impairment or laryngospasm after the procedure.
- ▶ Avoid using morphine sulfate in patients with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- ▶ Assist the patient to a comfortable position, and direct the patient to breathe normally during the beginning of the local anesthesia and to avoid unnecessary movement during the local anesthetic and the procedure. Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics).

Bronchoscopy

- ▶ Record baseline vital signs.
- ▶ The patient is positioned in relation to the type of anesthesia being used. If local anesthesia is used, the patient is seated and the tongue and oropharynx are sprayed and swabbed with anesthetic before the bronchoscope is inserted. For general anesthesia, the patient is placed in a supine position with the neck hyperextended. After anesthesia, the

INTRATEST:

Potential Complications:

Complications associated with bronchoscopy are rare but may include

patient is kept in supine or shifted to a side-lying position and the bronchoscope is inserted. After inspection, the samples are collected from suspicious sites by bronchial brush or biopsy forceps.

Expectorated Specimen

- ▶ Ask the patient to sit upright, with assistance and support (e.g., with an overbed table) as needed.
- ▶ Ask the patient to take two or three deep breaths and cough deeply. Any sputum raised should be expectorated directly into a sterile sputum collection container.
- ▶ If the patient is unable to produce the desired amount of sputum, several strategies may be attempted. One approach is to have the patient drink two glasses of water, and then assume the position for postural drainage of the upper and middle lung segments. Effective coughing may be assisted by placing either the hands or a pillow over the diaphragmatic area and applying slight pressure.
- ▶ Another approach is to place a vaporizer or other humidifying device at the bedside. After sufficient exposure to adequate humidification, postural drainage of the upper and middle lung segments may be repeated before attempting to obtain the specimen.
- ▶ Other methods may include obtaining an order for an expectorant to be administered with additional water approximately 2 hr before attempting to obtain the specimen. Chest percussion and postural drainage of all lung segments may also be employed. If the patient is still unable to raise sputum, the use of an ultrasonic nebulizer ("induced sputum") may be necessary; this is usually done by a respiratory therapist.

Tracheal Suctioning

- ▶ Obtain the necessary equipment, including a suction device, suction kit, and Lukens tube or in-line trap.
- ▶ Position the patient with head elevated as high as tolerated.
- ▶ Put on sterile gloves. Maintain the dominant hand as sterile and the non-dominant hand as clean.

- ▶ Using the sterile hand, attach the suction catheter to the rubber tubing of the Lukens tube or in-line trap. Then attach the suction tubing to the male adapter of the trap with the clean hand. Lubricate the suction catheter with sterile saline.
- ▶ Tell nonintubated patients to protrude the tongue and to take a deep breath as the suction catheter is passed through the nostril. When the catheter enters the trachea, a reflex cough is stimulated; immediately advance the catheter into the trachea and apply suction. Maintain suction for approximately 10 sec, but never longer than 15 sec. Withdraw the catheter without applying suction. Separate the suction catheter and suction tubing from the trap, and place the rubber tubing over the male adapter to seal the unit.
- ▶ For intubated patients or patients with a tracheostomy, the previous procedure is followed except that the suction catheter is passed through the existing endotracheal or tracheostomy tube rather than through the nostril. The patient should be hyperoxygenated before and after the procedure in accordance with standard protocols for suctioning these patients.
- ▶ Generally, a series of three to five early morning sputum samples are collected in sterile containers. If leprosy is suspected, obtain a smear from nasal scrapings or a biopsy specimen from lesions in a sterile container.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow

before allowing the patient to attempt liquids or solid foods.

- ▶ Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.
- ▶ Monitor vital signs and compare with baseline values every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Emergency resuscitation equipment should be readily available if the vocal cords become spastic after intubation.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breathing sounds over the affected area. Report any symptoms to the HCP.
- ▶ Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.
- ▶ Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ **Nutritional Considerations:** Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons, including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C are also important to prevent pulmonary infection and to decrease the extent of lung tissue damage.

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient to use lozenges or gargle for throat discomfort. Inform the patient of smoking cessation programs as appropriate. The importance of following the prescribed diet should be stressed to the patient/caregiver. Educate the patient regarding access to counseling services, as appropriate. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antibodies, anti-glomerular basement membrane, arterial/alveolar oxygen ratio, blood gases, bronchoscopy, chest x-ray, complete blood count, CT thoracic, cultures (fungal, sputum, throat, viral), cytology sputum, gallium scan, Gram stain, lung perfusion scan, lung ventilation scan, MRI chest, mediastinoscopy, pleural fluid analysis, pulmonary function tests, and TB tests.
- ▶ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Culture, Bacterial, Anal/Genital, Ear, Eye, Skin, and Wound

SYNONYM/ACRONYM: N/A.

COMMON USE: To identify pathogenic bacterial organisms as an indicator for appropriate therapeutic interventions for multiple sites of infection.

SPECIMEN: Sterile fluid or swab from affected area placed in transport media tube provided by laboratory.

NORMAL FINDINGS: (Method: Culture aerobic and/or anaerobic on selected media; cell culture followed by use of direct immunofluorescence, nucleic acid amplification and DNA probe assays [e.g., Gen-Probe] are available for identification of *Neisseria gonorrhoeae* and *Chlamydia trachomatis*.) Negative: no growth of pathogens.

DESCRIPTION: When indicated by patient history, anal and genital cultures may be performed to isolate the organism responsible for sexually transmitted disease. Group B streptococcus (GBS) is a significant and serious neonatal infection. The Centers for Disease Control and Prevention (CDC) recommends universal GBS screening for all pregnant women at 35 to 37 wk gestation. Rapid GBS test kits can provide results within minutes on vaginal or rectal fluid swab specimens submitted in a sterile red-top tube.

Ear and eye cultures are performed to isolate the organism responsible for chronic or acute infectious disease of the ear and eye.

Skin and soft tissue samples from infected sites must be collected carefully to avoid contamination from the surrounding normal skin flora. Skin and tissue infections may be caused by both aerobic and anaerobic organisms.

Therefore, a portion of the sample should be placed in aerobic and a portion in anaerobic transport media. Care must be taken to use transport media that are approved by the laboratory performing the testing.

Sterile fluids can be collected from the affected site. Refer to related body fluid monographs (i.e., amniotic fluid, cerebrospinal fluid, pericardial fluid, peritoneal fluid, pleural fluid, synovial fluid) for specimen collection.

A wound culture involves collecting a specimen of exudates, drainage, or tissue so that the causative organism can be isolated and pathogens identified. Specimens can be obtained from superficial and deep wounds.

Optimally, specimens should be obtained before antibiotic use. The method used to culture and grow the organism depends on the suspected infectious organism. There are transport media specifically for bacterial agents.

The laboratory will select the appropriate media for suspect organisms and will initiate antibiotic sensitivity testing if indicated by test results. Sensitivity testing identifies the antibiotics to which organisms are susceptible to ensure an effective treatment plan.

This procedure is contraindicated for: N/A

INDICATIONS

Anal/Genital

- Assist in the diagnosis of sexually transmitted diseases.
- Determine the cause of genital itching or purulent drainage.
- Determine effective antimicrobial therapy specific to the identified pathogen.
- Routine prenatal screening for vaginal and rectal GBS colonization.

Ear

- Isolate and identify organisms responsible for ear pain, drainage, or changes in hearing.
- Isolate and identify organisms responsible for outer-, middle-, or inner-ear infection.
- Determine effective antimicrobial therapy specific to the identified pathogen.

Eye

- Isolate and identify pathogenic microorganisms responsible for infection of the eye.
- Determine effective antimicrobial therapy specific to identified pathogen.

Skin

- Isolate and identify organisms responsible for skin eruptions, drainage, or other evidence of infection.
- Determine effective antimicrobial therapy specific to the identified pathogen.

Sterile Fluids

- Isolate and identify organisms before surrounding tissue becomes infected.
- Determine effective antimicrobial therapy specific to the identified pathogen.

Wound

- Detect abscess or deep-wound infectious process.
- Determine if an infectious agent is the cause of wound redness, warmth, or edema with drainage at a site.
- Determine presence of infectious agents in a stage 3 and stage 4 decubitus ulcer.
- Isolate and identify organisms responsible for the presence of pus or other exudate in an open wound.
- Determine effective antimicrobial therapy specific to the identified pathogen.

POTENTIAL DIAGNOSIS

Positive findings in

Anal/Endocervical/Genital

Infections or carrier states are caused by the following organisms: *C. trachomatis*, obligate intra-cellular bacteria without a cell wall, gram variable *Gardnerella vaginalis*, gram negative *N. gonorrhoeae*, *Treponema pallidum*, and toxin-producing strains of gram positive *Staphylococcus aureus*, and gram positive GBS.

Ear

Commonly identified gram negative organisms include *Escherichia coli*, *Proteus* spp., *Pseudomonas aeruginosa*, gram positive *S. aureus*, and β -hemolytic streptococci.

Eye

Commonly identified organisms include *C. trachomatis* (transmitted to newborns from infected mothers), gram negative *Haemophilus influenzae* (transmitted to newborns from

infected mothers), *H. aegyptius*, *N. gonorrhoeae* (transmitted to newborns from infected mothers), *P. aeruginosa*, gram positive *S. aureus*, and *Streptococcus pneumoniae*.

Skin

Commonly identified gram negative organisms include *Bacteroides*, *Pseudomonas*, gram positive *Clostridium*, *Corynebacterium*, staphylococci, and group A streptococci.

Sterile Fluids

Commonly identified pathogens include gram negative *Bacteroides*, *E. coli*, *P. aeruginosa*, gram positive *Enterococcus* spp., and *Peptostreptococcus* spp.

Wound

Aerobic and anaerobic microorganisms can be identified in wound culture specimens. Commonly identified gram negative organisms include *Klebsiella*, *Proteus*, *Pseudomonas*, gram-positive *Clostridium perfringens*, *S. aureus*, and group A streptococci.

CRITICAL FINDINGS

- *Listeria* in genital cultures; listeriosis in pregnant women may result in premature birth, miscarriage, or still-birth. The earlier in pregnancy the infection occurs, the more likely that it will lead to miscarriage or fetal death. After 20 weeks gestation, listeriosis is more likely to cause premature labor and birth.
- Methicillin-resistant *S. aureus* (MRSA) in skin or wound cultures

Note and immediately report to the health-care provider (HCP) positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). Lists of specific organisms may vary among facilities; specific organisms are required to be reported to local, state, and national departments of health.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Failure to collect adequate specimen, improper collection or storage technique, and failure to transport specimen in a timely fashion are causes for specimen rejection.
- Pretest antimicrobial therapy will delay or inhibit the growth of pathogens.
- Testing specimens more than 1 hr after collection may result in decreased growth or no growth of organisms.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that test can assist in identification of the organism causing infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens.

- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain, as appropriate, a history of sexual activity.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent medications that can interfere with test results.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 min. Address concerns about pain and explain that there may be some discomfort during the specimen collection. Instruct female patients not to douche for 24 hr before a cervical or vaginal specimen is to be obtained.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with medication restrictions prior to the procedure.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, specify the exact specimen source/origin (e.g., vaginal lesion or ear, left or right, as appropriate), patient age and gender, date and time of collection, and any medication the patient is taking that may interfere with the test results (e.g., antibiotics). Do not freeze the specimen or allow it to dry. Chlamydia is an intracellular obligate pathogen. Culture of infected epithelial cells is considered the gold standard for the

identification of chlamydia because of the higher sensitivity of nucleic acid amplification or DNA probe assays relative to antibody assays. Therefore, culture should always be the test of choice in cases of suspected or known child abuse.

Anal

- ▶ Place the patient in a lithotomy or side-lying position and drape for privacy. Insert the swab 1 in. into the anal canal and rotate, moving it from side to side to allow it to come into contact with the microorganisms. Remove the swab. Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium. Repeat with a clean swab if the swab is pushed into feces.

Genital

Female Patient

- ▶ Position the patient on the gynecological examination table with the feet up in stirrups. Drape the patient's legs to provide privacy and reduce chilling.
- ▶ Cleanse the external genitalia and perineum from front to back with towlettes provided in culture kit. Using a Culturette swab, obtain a sample of the lesion or discharge from the urethra or vulva. Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.
- ▶ To obtain a vaginal and endocervical culture, insert a water-lubricated vaginal speculum. Insert the swab into the cervical orifice and rotate the swab to collect the secretions containing the microorganisms. Remove and place in the appropriate culture medium or Gen-Probe transport tube. Material from the vagina can be collected by moving a swab along the sides of the vaginal mucosa. The swab is removed and then placed in a tube of saline medium.

Male Patient

- ▶ To obtain a urethral culture, cleanse the penis (retracting the foreskin), have

the patient milk the penis to express discharge from the urethra. Insert a swab into the urethral orifice and rotate the swab to obtain a sample of the discharge. Place the swab in the Culturette or Gen-Probe transport tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.

Ear

- ▶ Cleanse the area surrounding the site with a swab containing cleaning solution to remove any contaminating material or flora that have collected in the ear canal. If needed, assist the appropriate HCP in removing any cerumen that has collected.
- ▶ Insert a Culturette swab approximately 1/4 in. into the external ear canal. Rotate the swab in the area containing the exudate. Carefully remove the swab, ensuring that it does not touch the side or opening of the ear canal.
- ▶ Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.

Eye

- ▶ Pass a moistened swab over the appropriate site, avoiding eyelid and eyelashes unless those areas are selected for study. Collect any visible pus or other exudate. Place the swab in the Culturette or Gen-Probe transport tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.
- ▶ An appropriate HCP should perform procedures requiring eye culture.

Skin

- ▶ Assist the appropriate HCP in obtaining a skin sample from several areas of the affected site. If indicated, the dark, moist areas of the folds of the skin and outer growing edges of the infection where microorganisms are most likely to flourish should be selected. Place the scrapings in a collection container or spread on a slide. Aspirate any fluid from a pustule or vesicle using a sterile needle and tuberculin syringe. The

exudate will be flushed into a sterile collection tube. If the lesion is not fluid filled, open the lesion with a scalpel and swab the area with a sterile cotton-tipped swab. Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium.

Sterile Fluid

- ▶ Refer to related body fluid monographs (i.e., amniotic fluid, cerebrospinal fluid, pericardial fluid, peritoneal fluid, pleural fluid, synovial fluid) for specimen collection.

Wound

- ▶ Place the patient in a comfortable position, and drape the site to be cultured. Cleanse the area around the wound to remove flora indigenous to the skin.
- ▶ Place a Culturette swab in a superficial wound where the exudate is the most excessive without touching the wound edges. Place the swab in the Culturette tube, and squeeze the bottom of the tube to release the transport medium. Ensure that the end of the swab is immersed in the medium. Use more than one swab and Culturette tube to obtain specimens from other areas of the wound.
- ▶ To obtain a deep wound specimen, insert a sterile syringe and needle into the wound and aspirate the drainage. Following aspiration, inject the material into a tube containing an anaerobic culture medium.

General

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Instruct the patient to resume usual medication as directed by the HCP.
- ▶ Instruct the patient to report symptoms such as pain related to tissue inflammation or irritation.
- ▶ Instruct the patient to begin antibiotic therapy, as prescribed. Instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.

- ▶ Inform the patient that a repeat culture may be needed in 1 wk after completion of the antimicrobial regimen.
- ▶ Advise the patient that final test results may take 24 to 72 hr depending on the organism suspected but that antibiotic therapy may be started immediately.

Anal/Endocervical/Genital

- ▶ Inform the patient that final results may take from 24 hr to 4 wk, depending on the test performed.
- ▶ Advise the patient to avoid sexual contact until test results are available.
- ▶ Instruct the patient in vaginal suppository and medicated cream installation and administration of topical medication to treat specific conditions, as indicated.
- ▶ Inform infected patients that all sexual partners must be tested for the microorganism.
- ▶ Inform the patient that positive culture findings for certain organisms must be reported to a local health department official, who will question him or her regarding sexual partners.
- ▶ **Social and Cultural Considerations:** Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks of sexually transmitted diseases. It is also important to address problems the patient may experience (e.g., guilt, depression, anger).

Wound

- ▶ Instruct the patient in wound care and nutritional requirements (e.g., protein, vitamin C) to promote wound healing.

General

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information

regarding the clinical implications of the test results, as appropriate.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Emphasize the importance of reporting continued signs and symptoms of the infection. Provide information regarding vaccine-preventable diseases where indicated (e.g., cervical cancer, hepatitis A and B, human papillomavirus). Provide contact information, if desired, for the CDC (www.cdc.gov/vaccines/vpd-vac). Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications (oral, topical, drops). Instruct the patient in the proper use of sterile technique for cleansing the affected site and application of dressings, as directed. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include relevant amniotic fluid analysis, antimicrobial drugs, audiometry hearing loss, biopsy site, CSF analysis, culture viral, Gram stain, otoscopy, pericardial fluid analysis, Pap smear, peritoneal fluid analysis, pleural fluid analysis, procalcitonin, spondee speech reception threshold, synovial fluid analysis, syphilis serology, tuning fork tests, vitamin C, and zinc.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Culture, Bacterial, Blood

SYNONYM/ACRONYM: N/A.

COMMON USE: To identify pathogenic bacterial organisms in the blood as an indicator for appropriate therapeutic interventions for sepsis.

SPECIMEN: Whole blood collected in bottles containing standard aerobic and anaerobic culture media; 10 to 20 mL for adult patients or 1 to 5 mL for pediatric patients.

NORMAL FINDINGS: (Method: Growth of organisms in standard culture media identified by radiometric or infrared automation, by manual reading of subculture, or PCR.) Negative: no growth of pathogens.

DESCRIPTION: Pathogens can enter the bloodstream from soft-tissue infection sites, contaminated IV lines, or invasive procedures (e.g., surgery, tooth extraction, cystoscopy). Blood cultures are collected whenever bacteremia (bacterial infection of the blood) or septicemia (a condition of systemic infection caused by pathogenic organisms or their toxins) is suspected. Although mild bacteremia is found in many infectious diseases, a persistent, continuous, or recurrent bacteremia indicates a more serious condition that may require immediate treatment. Early detection of pathogens in the blood may aid in making clinical and etiological diagnoses.

Blood cultures can detect the presence of bacteria and fungi. Organisms can be classified in a number of ways; blood culture findings use oxygen requirements to categorize findings into one of two groups. Blood culture begins with the introduction of a blood specimen into 2 types of culture medium. The medium is designed to promote the growth of

organisms; one group of organisms require oxygen (aerobic) and the other either requires sparing amounts to no oxygen at all (anaerobic).

A blood culture may also be done with an antimicrobial removal device (ARD) if antibiotic therapy is initiated prior to specimen collection. This involves transferring some of the blood sample into a special vial containing absorbent resins that remove antibiotics from the sample before the culture is performed.

Traditional automated culture methods entail incubation of inoculated culture containers for a specific length of time, at a specific temperature, and under other conditions suitable for growth. If organisms are present they will produce carbon dioxide as they metabolize the nutrients in the culture media. The presence of carbon dioxide in the culture is detected when the culture bottles are “read” by an instrument at specified intervals over a period of time. There are a number of automated blood culture systems with sophisticated computerized

algorithms. The complex software allows for frequent monitoring of growth throughout the day and rapid interpretation of culture findings. With these systems as soon as a positive culture is detected, usually within 24–72 hr, the bottle can be removed from the system and a gram stain performed to provide a preliminary identification of the bacteria present. This preliminary report provides an opportunity for the HCP to initiate therapy. A sample from the positive blood culture bottle is then subcultured on the appropriate plated media for growth, isolation, and positive identification of the organism. The plated organisms are also used for sensitivity testing, if indicated. Sensitivity testing identifies the antibiotics to which the organisms are susceptible to ensure an effective treatment plan and can take several days. Negative cultures are generally removed from the automated culture system after 5 days and finalized as having “No Growth.” The subspecialty of microbiology has been revolutionized by molecular diagnostics. Molecular diagnostics involves the identification of specific sequences of DNA. The application of molecular diagnostics techniques, such as PCR, has led to the development of automated instruments that can identify a single infectious agent or multiple pathogens from a small amount of blood in less than 2 hr. The instruments can detect the presence of gram negative bacteria, gram positive bacteria, and yeast commonly associated with bloodstream infections. The instruments can also detect mutations in the genetic material of specific pathogens that code for antibiotic resistance.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine sepsis in the newborn as a result of prolonged labor, early rupture of membranes, maternal infection, or neonatal aspiration
- Evaluate chills and fever in patients with infected burns, urinary tract infections, rapidly progressing tissue infection, postoperative wound sepsis, and indwelling venous or arterial catheter
- Evaluate intermittent or continuous temperature elevation of unknown origin
- Evaluate persistent, intermittent fever associated with a heart murmur
- Evaluate a sudden change in pulse and temperature with or without chills and diaphoresis
- Evaluate suspected bacteremia after invasive procedures
- Identify the cause of shock in the postoperative period

POTENTIAL DIAGNOSIS

Positive findings in

- Bacteremia or septicemia: Gram-negative organisms such as *Aerobacter*; *Bacteroides*, *Brucella*, *Escherichia coli* and other coliform bacilli, *Haemophilus influenzae*, *Klebsiella*, *Pseudomonas aeruginosa*, and *Salmonella*.
- Bacteremia or septicemia: Gram-positive organisms such as *Clostridium perfringens*, *Enterococci*, *Listeria monocytogenes*, *Staphylococcus aureus*, *S. epidermidis*, and β -hemolytic streptococci.
- Plague
- Malaria (by special request, a stained capillary smear would be examined)
- Typhoid fever

Note: *Candida albicans* is a yeast that can cause disease and can be isolated by blood culture.

CRITICAL FINDINGS

- Positive findings in any sterile body fluid such as blood

Note and immediately report to the health-care provider (HCP) positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Assess for signs and symptoms of sepsis or development of septic shock to include change in body temperature (greater than 101.3F/38.5C or less than 95F/35C; decreased systolic blood pressure (less than 90 mm Hg); increased heart rate (greater than 90 beats per minute); sudden change in mental status (restlessness, agitation or confusion); significantly decreased urine output (less than 30 mL/hour); increased respirations (greater than

20 breaths per minute); change in extremities (pale, mottled, and/or cyanotic in appearance); decreased or absent peripheral pulses). Note and immediately report to the health-care provider (HCP) positive results and related symptoms. Lists of specific organisms may vary among facilities; specific organisms are required to be reported to local, state, and national departments of health.

INTERFERING FACTORS

- Pretest antimicrobial therapy will delay or inhibit growth of pathogens.
- Contamination of the specimen by the skin's resident flora may invalidate interpretation of test results.
- An inadequate amount of blood or number of blood specimens drawn for examination may invalidate interpretation of results.
- Testing specimens more than 1 hr after collection may result in decreased growth or no growth of organisms. Delay in transport of specimen to the laboratory may result in specimen rejection. Verify submission requirements with the laboratory prior to specimen collection.
- Collection of the specimen in an expired media tube will result in specimen rejection.
- Negative findings do not ensure the absence of infection.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to the materials in iodine solutions.
- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent medications that can interfere with test results.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 min. Inform the patient that multiple specimens may be required at timed intervals. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture. Consider the use of pediatric culture tubes, if appropriate for the patient's age.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with medication restrictions prior to the procedure.
- ▶ Avoid the use of iodine solutions if the patient has a history of severe allergic reaction to any of the materials in the iodine solution.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics). Perform a venipuncture; collect the specimen in the appropriate blood culture collection container.
- ▶ The high risk for contamination of blood cultures by skin and other flora can be dramatically reduced by careful preparation of the puncture site and collection containers before specimen collection. Cleanse the rubber stoppers of the collection containers with the appropriate disinfectant as recommended by the laboratory, allow to air-dry, and cleanse with 70% alcohol. Once the vein has been located by palpation, cleanse the site with 70% alcohol followed by swabbing with an iodine solution. The iodine solution should be swabbed in a circular, concentric motion, moving outward or away from the puncture site. The iodine solution should be allowed to completely dry before the sample is collected. If the patient is sensitive to iodine solutions, a double alcohol scrub or green soap may be substituted.
- ▶ If collection is performed by directly drawing the sample into a culture tube, fill the aerobic culture tube first.
- ▶ If collection is performed using a syringe, transfer the blood sample directly into each culture bottle.
- ▶ Remove the needle, and apply direct pressure with a dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.
- ▶ More than three sets of cultures per day do not significantly add to the likelihood of pathogen capture. Capture rates are more likely affected by obtaining a sufficient volume of blood per culture.
- ▶ The use of ARDs or resin bottles is costly and controversial with respect to their effectiveness versus standard culture techniques. They may be useful in selected cases, such as when septicemia or bacteremia is suspected after antimicrobial therapy has been initiated.

Disease Suspected	Recommended Collection
Bacterial pneumonia, fever of unknown origin, meningitis, osteomyelitis, sepsis	Two sets of cultures, each collected from a separate site, 30 min apart
Acute or subacute endocarditis	Three sets of cultures, each collected from a separate site, 30–40 min apart. If cultures are negative after 24–48 hr, repeat collections
Septicemia, fungal or mycobacterial infection in immunocompromised patient	Two sets of cultures, each collected from a separate site, 30–60 min apart (laboratory may use a lysis concentration technique to enhance recovery)
Septicemia, bacteremia after therapy has been initiated, or request to monitor effectiveness of antimicrobial therapy	Two sets of cultures, each collected from a separate site, 30–60 min apart (consider use of ARD to enhance recovery)

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medication as directed by the HCP.
- ▶ Cleanse the iodine solution from the collection site.
- ▶ Instruct the patient to report symptoms such as pain related to tissue inflammation or irritation.
- ▶ Instruct the patient to report fever, chills, and other signs and symptoms of acute infection to the HCP.
- ▶ Instruct the patient to begin antibiotic therapy, as prescribed. Instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- ▶ Inform the patient that preliminary results should be available in 24 to 72 hr, but final culture results are not available for 5 to 7 days. Test results for PCR methods are generally available a few hours after testing is completed.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further

testing, treatment, or referral to another HCP. Emphasize the importance of reporting continued signs and symptoms of the infection. Provide information regarding vaccine-preventable diseases where indicated (e.g., *Haemophilus influenzae*, meningococcal disease). Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include bone scan, bronchoscopy, CBC, cultures (fungal, mycobacteria, throat, sputum, viral), CSF analysis, ESR, gallium scan, Gram stain, HIV-1/2 antibodies, MRI musculoskeletal, procalcitonin, PFT, radiography bone, and TB tests.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Culture, Bacterial, Sputum

SYNONYM/ACRONYM: Routine culture of sputum.

COMMON USE: To identify pathogenic bacterial organisms in the sputum as an indicator for appropriate therapeutic interventions for respiratory infections.

SPECIMEN: Sputum (10 to 15 mL).

NORMAL FINDINGS: (Method: Aerobic culture on selective and enriched media; microscopic examination of sputum by Gram stain.) The presence of normal upper respiratory tract flora should be expected. Tracheal aspirates and bronchoscopy samples can be contaminated with normal flora, but transtracheal aspiration specimens should show no growth. Normal respiratory flora include *Neisseria catarrhalis*, *Candida albicans*, diphtheroids, α -hemolytic streptococci, and some staphylococci. The presence of normal flora does not rule out infection. A normal Gram stain of sputum contains polymorphonuclear leukocytes, alveolar macrophages, and a few squamous epithelial cells.

DESCRIPTION: This test involves collecting a sputum specimen so the pathogen can be isolated and identified. The test results will reflect the type and number of organisms present in the specimen as well as the antibiotics to which the identified pathogenic organisms are susceptible. Sputum collected by expectoration or suctioning with catheters and by bronchoscopy cannot be cultured for anaerobic organisms; instead, transtracheal aspiration or lung biopsy must be used. The laboratory will initiate antibiotic sensitivity testing if indicated by test results. Sensitivity testing identifies antibiotics to which the organisms are susceptible to ensure an effective treatment plan.

This procedure is contraindicated for: N/A

INDICATIONS

Culture

- Assist in the diagnosis of respiratory infections, as indicated by the presence or absence of organisms in culture

Gram Stain

- Assist in the differentiation of gram-positive from gram-negative bacteria in respiratory infection
- Assist in the differentiation of sputum from upper respiratory tract secretions, the latter being indicated by excessive squamous cells or absence of polymorphonuclear leukocytes

POTENTIAL DIAGNOSIS

- The major difficulty in evaluating results is in distinguishing organisms infecting the lower respiratory tract from organisms that have

colonized but not infected the lower respiratory tract. Review of the Gram stain assists in this process. The presence of greater than 25 squamous epithelial cells per low-power field (lpf) indicates oral contamination, and the specimen should be rejected. The presence of many polymorphonuclear neutrophils and few squamous epithelial cells indicates that the specimen was collected from an area of infection and is satisfactory for further analysis.

- Bacterial pneumonia can be caused by *Streptococcus pneumoniae*, *Haemophilus influenzae*, staphylococci, and some gram-negative bacteria. Other pathogens that can be identified by culture are *Corynebacterium diphtheriae*, *Klebsiella pneumoniae*, and *Pseudomonas aeruginosa*. Some infectious agents, such as *C. diphtheriae*, are more fastidious in their growth requirements and cannot be cultured and identified without special treatment. Suspicion of infection by less commonly identified and/or fastidious organisms must be communicated to the laboratory to ensure selection of the proper procedure required for identification.

CRITICAL FINDINGS

- *C. diphtheriae*
- *Legionella*

Note and immediately report to the health-care provider (HCP) positive results for bacterial pathogens or parasites.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). Lists of specific organisms may vary among facilities; specific organisms are required to be reported to local,

state, and national departments of health.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Contamination with oral flora may invalidate results.
- Specimen collection after antibiotic therapy has been initiated may result in inhibited or no growth of organisms.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent medications that can interfere with test results.
- ▶ Review the procedure with the patient. Reassure the patient that he or she will be able to breathe during the procedure if specimen collection is accomplished via suction method. Ensure that oxygen has been administered 20 to 30 min before the procedure if the specimen is to be obtained by tracheal suctioning. Address concerns about pain related to the procedure. Atropine is usually given before bronchoscopy examinations to reduce bronchial secretions and prevent vagally induced bradycardia. Meperidine (Demerol) or morphine may be given as a sedative. Lidocaine is sprayed in the patient's throat to reduce discomfort caused by the presence of the tube.
- ▶ Explain to the patient that the time it takes to collect a proper specimen varies according to the level of cooperation of the patient and the specimen collection site. Emphasize that sputum and saliva are not the same. Inform the patient that multiple specimens may be required at timed intervals.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Bronchoscopy

- ▶ Make sure a written and informed consent has been signed prior to the bronchoscopy/biopsy procedure and before administering any medications.
- ▶ Other than antimicrobial drugs, there are no medication restrictions, unless by medical direction.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia

(monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

Expectorated Specimen

- ▶ Additional liquids the night before may assist in liquefying secretions during expectoration the following morning.
- ▶ Assist the patient with oral cleaning before sample collection to reduce the amount of sample contamination by organisms that normally inhabit the mouth.
- ▶ Instruct the patient not to touch the edge or inside of the container with the hands or mouth.
- ▶ Other than antimicrobial drugs, there are no medication restrictions, unless by medical direction.
- ▶ There are no food or fluid restrictions, unless by medical direction.

Tracheal Suctioning

- ▶ Assist in providing extra fluids, unless contraindicated, and proper humidification to decrease tenacious secretions. Inform the patient that increasing fluid intake before retiring on the night before the test aids in liquefying secretions and may make it easier to expectorate in the morning. Also explain that humidifying inspired air also helps liquefy secretions.
- ▶ Other than antimicrobial drugs, there are no medication restrictions, unless by medical direction.
- ▶ There are no food or fluid restrictions, unless by medical direction.
- ▶ If the specimen is collected by expectoration or tracheal suctioning, there are no food, fluid, or medication restrictions (except antibiotics), unless by medical direction.

INTRATEST:

Potential Complications:

Complications associated with bronchoscopy are rare but may include bleeding, bronchial perforation, bronchospasm, infection, laryngospasm, and pneumothorax.

- ▶ Ensure that the patient has complied with dietary and medication restrictions prior to the bronchoscopy procedure.
- ▶ Have patient remove dentures, contact lenses, eyeglasses, and jewelry. Notify the HCP if the patient has permanent crowns on teeth. Have the patient remove clothing and change into a gown for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available. Keep resuscitation equipment on hand in case of respiratory impairment or laryngospasm after the procedure.
- ▶ Avoid using morphine sulfate in patients with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Assist the patient to a comfortable position and direct the patient to breathe normally during the beginning of the general anesthesia and to avoid unnecessary movement during the local anesthetic and the procedure. Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics). Collect the specimen in the appropriate sterile collection container.

Bronchoscopy

- ▶ Record baseline vital signs.
- ▶ The patient is positioned in relation to the type of anesthesia being used. If local anesthesia is used, the patient is seated and the tongue and oropharynx are sprayed and swabbed with anesthetic before the bronchoscope is inserted. For general anesthesia, the patient is placed in a supine position with the neck hyperextended. After anesthesia, the patient is kept in supine or shifted to a side-lying

position and the bronchoscope is inserted. After inspection, the samples are collected from suspicious sites by bronchial brush or biopsy forceps.

Expectorated Specimen

- ▶ Ask the patient to sit upright, with assistance and support (e.g., with an overbed table) as needed.
- ▶ Ask the patient to take two or three deep breaths and cough deeply. Any sputum raised should be expectorated directly into a sterile sputum collection container.
- ▶ If the patient is unable to produce the desired amount of sputum, several strategies may be attempted. One approach is to have the patient drink two glasses of water, and then assume the position for postural drainage of the upper and middle lung segments. Effective coughing may be assisted by placing either the hands or a pillow over the diaphragmatic area and applying slight pressure.
- ▶ Another approach is to place a vaporizer or other humidifying device at the bedside. After sufficient exposure to adequate humidification, postural drainage of the upper and middle lung segments may be repeated before attempting to obtain the specimen.
- ▶ Other methods may include obtaining an order for an expectorant to be administered with additional water approximately 2 hr before attempting to obtain the specimen. Chest percussion and postural drainage of all lung segments may also be employed. If the patient is still unable to raise sputum, the use of an ultrasonic nebulizer (“induced sputum”) may be necessary; this is usually done by a respiratory therapist.

Tracheal Suctioning

- ▶ Obtain the necessary equipment, including a suction device, suction kit, and Lukens tube or in-line trap.
- ▶ Position the patient with head elevated as high as tolerated.
- ▶ Put on sterile gloves. Maintain the dominant hand as sterile and the nondominant hand as clean.
- ▶ Using the sterile hand, attach the suction catheter to the rubber tubing of the Lukens tube or in-line trap. Then attach the suction tubing to the male

adapter of the trap with the clean hand. Lubricate the suction catheter with sterile saline.

- ▶ Tell nonintubated patients to protrude the tongue and to take a deep breath as the suction catheter is passed through the nostril. When the catheter enters the trachea, a reflex cough is stimulated; immediately advance the catheter into the trachea and apply suction. Maintain suction for approximately 10 sec, but never longer than 15 sec. Withdraw the catheter without applying suction. Separate the suction catheter and suction tubing from the trap, and place the rubber tubing over the male adapter to seal the unit.
- ▶ For intubated patients or patients with a tracheostomy, the previous procedure is followed except that the suction catheter is passed through the existing endotracheal or tracheostomy tube rather than through the nostril. The patient should be hyperoxygenated before and after the procedure in accordance with standard protocols for suctioning these patients.
- ▶ Generally, a series of three to five early morning sputum samples are collected in sterile containers.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume preoperative diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.
- ▶ Monitor vital signs and compare with baseline values every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor

temperature every 4 hr for 24 hr. Notify the HCP if temperature is elevated.

Protocols may vary among facilities.

- ▶ Emergency resuscitation equipment should be readily available if the vocal cords become spastic after intubation.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breathing sounds over the affected area. Report any symptoms to the HCP.
- ▶ Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.
- ▶ Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ **Nutritional Considerations:** Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C are also important to prevent pulmonary infection and to decrease the extent of lung tissue damage.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient to use lozenges or gargle for throat discomfort. Inform the patient of smoking cessation programs as appropriate. The importance of following the prescribed diet should be

stressed to the patient/caregiver. Educate the patient regarding access to counseling services, as appropriate. Provide information regarding vaccine preventable diseases where indicated (e.g., H1N1 flu, *Haemophilus influenzae*, seasonal influenza, pertussis, pneumococcal disease). Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antibodies, anti-glomerular basement membrane, arterial/alveolar oxygen ratio, biopsy lung, blood gases, bronchoscopy, chest x-ray, CBC, CT thoracic, culture (fungal, mycobacterium, throat, viral), cytology sputum, gallium scan, Gram stain/acid-fast stain, HIV-1/2 antibodies, lung perfusion scan, lung ventilation scan, MRI chest, mediastino-scopy, pleural fluid analysis, PFT, and TB tests.
- ▶ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Culture, Bacterial, Stool

SYNONYM/ACRONYM: N/A.

COMMON USE: To identify pathogenic bacterial organisms in the stool as an indicator for appropriate therapeutic interventions to treat organisms such as *Clostridium difficile* and *Escherichia coli*.

SPECIMEN: Fresh, random stool collected in a clean plastic container.

NORMAL FINDINGS: (Method: Culture on selective media for identification of pathogens usually to include *Salmonella*, *Shigella*, *Escherichia coli* O157:H7, *Yersinia enterocolitica*, and *Campylobacter*; latex agglutination or enzyme immunoassay for *Clostridium* A and B toxins). PCR may be used to identify bacterial, protozoan, or viral pathogens. Negative: No growth of pathogens. Normal fecal flora is 96% to 99% anaerobes and 1% to 4% aerobes. Normal flora present may include *Bacteroides*, *Candida albicans*, *Clostridium*, *Enterococcus*, *E. coli*, *Proteus*, *Pseudomonas*, and *Staphylococcus aureus*.

DESCRIPTION: Stool culture involves collecting a sample of feces so that organisms present can be isolated and identified. Certain bacteria are normally found in feces. However,

when overgrowth of these organisms occurs or pathological organisms are present, diarrhea or other signs and symptoms of systemic infection occur. These symptoms

are the result of damage to the intestinal tissue by the pathogenic organisms. Routine stool culture normally screens for a small number of common pathogens associated with food poisoning, such as *S. aureus*, *Salmonella*, and *Shigella*. Identification of other bacteria is initiated by special request or upon consultation with a microbiologist when there is knowledge of special circumstances. An example of this situation is an outbreak of *C. difficile* in a nursing home or hospital unit where the infection can spread rapidly from one person to the next. A life-threatening *C. difficile* infection of the bowel may occur in patients who are immunocompromised or are receiving broad-spectrum antibiotic therapy (e.g., clindamycin, ampicillin, cephalosporins). The bacteria release a toxin that causes necrosis of the colon tissue. The toxin can be more rapidly identified from a stool sample using an immunochemical method than from a routine culture. Appropriate interventions can be quickly initiated and might include IV replacement of fluid and electrolytes, cessation of broad-spectrum antibiotic administration, and institution of vancomycin or metronidazole antibiotic therapy. The laboratory will initiate antibiotic sensitivity testing if indicated by test results. Sensitivity testing identifies the antibiotics to which organisms are susceptible to ensure an effective treatment plan. The subspecialty of microbiology has been revolutionized by molecular diagnostics. Molecular diagnostics involves the identification of specific sequences of DNA. The application of molecular diagnostics techniques, such as PCR, has led to the development of automated

instruments that can identify a single infectious agent or multiple pathogens from a small amount of stool in less than 2 hr. The instruments can detect the presence of bacteria, viruses, or protozoans commonly associated with gastrointestinal infections.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in establishing a diagnosis for diarrhea of unknown etiology
- Identify pathogenic organisms causing gastrointestinal disease and carrier states

POTENTIAL DIAGNOSIS

Positive findings in

- Bacterial infection: Gram-negative organisms such as *Aeromonas* spp., *Campylobacter*, *E. coli* including serotype O157:H7, *Plesiomonas shigelloides*, *Salmonella*, *Shigella*, *Vibrio*, and *Yersinia*.
- Bacterial infection: Gram-positive organisms such as *Bacillus cereus*, *C. difficile*, and *Listeria*. Isolation of *Staphylococcus aureus* may indicate infection or a carrier state
- Botulism: *Clostridium botulinum* (the bacteria must also be isolated from the food or the presence of toxin confirmed in the stool specimen)
- Parasitic enterocolitis

CRITICAL FINDINGS

- Bacterial pathogens: *Campylobacter*, *C. difficile*, *E. coli* including O157:H7, *Listeria*, *Rotavirus* (especially in children), *Salmonella*, *Shigella*, *Vibrio*, *Yersinia*, or parasites *Acanthamoeba*, *Ascaris* (hookworm), *Cyclospora*, *Cryptosporidium*, *Entamoeba histolytica*, *Giardia*, and *Strongyloides* (tapeworm), parasitic ova, proglottid, and larvae.

Note and immediately report to the health-care provider (HCP) positive results for bacterial pathogens or parasites and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). Lists of specific organisms may vary among facilities; specific organisms are required to be reported to local, state, and national departments of health.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- A rectal swab does not provide an adequate amount of specimen for evaluating the carrier state and should be avoided in favor of a standard stool specimen.
- A rectal swab should never be submitted for *Clostridium* toxin studies. Specimens for *Clostridium* toxins should be refrigerated if they are not immediately transported to the laboratory because toxins degrade rapidly.
- A rectal swab should never be submitted for *Campylobacter* culture. Excessive exposure of the sample to air or room temperature may damage this bacterium so that it will not grow in the culture.

- Therapy with antibiotics before specimen collection may decrease the type and the amount of bacteria.
- Failure to transport the culture within 1 hr of collection or urine contamination of the sample may affect results.
- Barium and laxatives used less than 1 wk before the test may reduce bacterial growth.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens.
- ▶ Obtain a history of the patient's gastrointestinal and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a history of the patient's travel to foreign countries.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent medications that can interfere with test results.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be some discomfort during the specimen collection. Inform the patient that specimen collection takes approximately 5 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with medication restrictions prior to the procedure.

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics).
- ▶ Collect a stool specimen directly into a clean container. If the patient requires a bedpan, make sure it is clean and dry, and use a tongue blade to transfer the specimen to the container. Make sure representative portions of the stool are sent for analysis. Note specimen appearance on collection container label.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medication as directed by the HCP.
- ▶ Instruct the patient to report symptoms such as pain related to tissue inflammation or irritation.
- ▶ Advise the patient that final test results for culture may take up to 72 hr but that antibiotic therapy may be started immediately. Test results for PCR methods are generally

- available a few hours after testing is completed. Instruct the patient about the importance of completing the entire course of antibiotic therapy even if no symptoms are present. Note: Antibiotic therapy is frequently contraindicated for *Salmonella* infection unless the infection has progressed to a systemic state.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Emphasize the importance of reporting continued signs and symptoms of the infection. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include capsule endoscopy, colonoscopy, fecal analysis, Gram stain, ova and parasites, and proctosigmoidoscopy.
- ▶ Refer to the Gastrointestinal and Immune systems tables at the end of the book for related tests by body system.

Culture, Bacterial, Throat or Nasopharyngeal

SYNONYM/ACRONYM: Routine throat culture.

COMMON USE: To identify pathogenic bacterial organisms in the throat and nares as an indicator for appropriate therapeutic interventions. Treat infections such as pharyngitis, thrush, strep throat, and screen for methicillin-resistant *Staphylococcus aureus* (MRSA).

SPECIMEN: Throat or nasopharyngeal swab.

NORMAL FINDINGS: (Method: Aerobic culture) No growth.

DESCRIPTION: The routine throat culture is a commonly ordered test to screen for the presence of group A β -hemolytic streptococci.

Streptococcus pyogenes is the gram-positive organism that most commonly causes acute pharyngitis. The more dangerous sequelae of scarlet fever, rheumatic heart disease, and glomerulonephritis are less frequently seen because of the early treatment of infection at the pharyngitis stage. There are a number of other bacterial agents responsible for pharyngitis. Specific cultures can be set up to detect other pathogens such as *Bordetella* (gram negative), *Corynebacteria* (gram positive), *Haemophilus* (gram negative), or *Neisseria* (gram negative) if they are suspected or by special request from the health-care provider (HCP). *Corynebacterium diphtheriae* is the causative agent of diphtheria. *Neisseria gonorrhoeae* is a sexually transmitted pathogen. In children, a positive throat culture for *Neisseria* usually indicates sexual abuse. The laboratory will initiate antibiotic sensitivity testing if indicated by test results. Sensitivity testing identifies the antibiotics to which the organisms are susceptible to ensure an effective treatment plan.

This procedure is contraindicated for

-  Patients with epiglottitis. In cases of acute epiglottitis, the throat culture may need to be obtained in the operating room or other appropriate location where the required emergency equipment and trained personnel can safely perform the procedure.

INDICATIONS

- Assist in the diagnosis of bacterial infections such as tonsillitis, diphtheria, gonorrhea, or pertussis

- Assist in the diagnosis of upper respiratory infections resulting in bronchitis, pharyngitis, croup, and influenza
- Isolate and identify group A β -hemolytic streptococci as the cause of strep throat, acute glomerulonephritis, scarlet fever, or rheumatic fever

POTENTIAL DIAGNOSIS

Reports on cultures that are positive for group A β -hemolytic streptococci are generally available within 24 to 48 hr. Cultures that report on normal respiratory flora are issued after 48 hr. Culture results of no growth for *Corynebacterium* require 72 hr to report; 48 hr are required to report negative *Neisseria* cultures.

CRITICAL FINDINGS

- Culture: Growth of *Corynebacterium* or MRSA

Note and immediately report to the HCP positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting HCP. Lists of specific organisms may vary among facilities; specific organisms are required to be reported to local, state, and national departments of health.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely

report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Contamination with oral flora may invalidate results.
- Specimen collection after antibiotic therapy has been initiated may result in inhibited or no growth of organisms.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent medications that can interfere with test results.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be some discomfort during the specimen collection. The time it takes to collect a proper specimen varies according to the level of cooperation of the patient. Inform the patient that specimen collection takes approximately 5 min.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

INTRATEST:

Potential Complications:

In cases of epiglottitis, do not swab the throat. This can cause a laryngospasm

resulting in a loss of airway. Symptoms associated with epiglottitis include sore throat, difficulty swallowing, difficulty breathing (**related to blocked airway**), blue skin (especially around the lips), confusion, irritability, and sluggishness (**related to decreased oxygen levels**).

Potential interactions include stabilizing the airway, monitoring vital signs, and administering the appropriate medications which may include antibiotics.

Antibiotics may be administered before the results of the culture are obtained.

- ▶ Ensure that the patient has complied with medication restrictions prior to the procedure.
- ▶ Have emergency equipment readily available. Keep resuscitation equipment on hand in case of respiratory impairment or laryngospasm after the procedure.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics).
- ▶ To collect the throat culture, tilt the patient's head back. Swab both tonsillar pillars and oropharynx with the sterile Culturette. A tongue depressor can be used to ensure that contact with the tongue and uvula is avoided.
- ▶ A nasopharyngeal specimen is collected through the use of a flexible probe inserted through the nose and directed toward the back of the throat.
- ▶ Place the swab in the Culturette tube and squeeze the bottom of the Culturette tube to release the liquid transport medium. Ensure that the end of the swab is immersed in the liquid transport medium.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- ▶ Instruct the patient to resume usual medication as directed by the HCP.
- ▶ Instruct the patient to notify the HCP immediately if difficulty in breathing or swallowing occurs or if bleeding occurs.
- ▶ Instruct the patient to perform mouth care after the specimen has been obtained.
- ▶ Provide comfort measures and treatment such as antiseptic gargles; inhalants; and warm, moist applications as needed. A cool beverage may aid in relieving throat irritation caused by coughing or suctioning.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ **Nutritional Considerations:** Dehydration can be seen in patients with a bacterial throat infection due to pain with swallowing. Pain medications reduce patient's dysphagia and allow for adequate intake of fluids and foods.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

Instruct the patient to use lozenges or gargle for throat discomfort. Inform the patient of smoking cessation programs as appropriate. Emphasize the importance of reporting continued signs and symptoms of the infection. Provide information regarding vaccine-preventable diseases where indicated (e.g., diphtheria H1N1 flu, Haemophilus influenza, seasonal influenza, pneumococcal disease). Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CBC, Gram stain, and group A streptococcal (rapid) screen.
- ▶ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Culture, Bacterial, Urine

SYNONYM/ACRONYM: Routine urine culture.

COMMON USE: To identify the pathogenic bacterial organisms in the urine as an indicator for appropriate therapeutic interventions to treat urinary tract infections.

SPECIMEN: Urine (5 mL) collected in a sterile plastic collection container. Transport tubes containing a preservative are highly recommended if testing will not occur within 2 hr of collection.

NORMAL FINDINGS: (Method: Culture on selective and enriched media) Negative: no growth.

DESCRIPTION: A urine culture involves collecting a urine specimen so that the organism causing

disease can be isolated and identified. Urine can be collected by clean catch, urinary catheterization,

or suprapubic aspiration. The severity of the infection or contamination of the specimen can be determined by knowing the type and number of organisms (colonies) present in the specimen. The laboratory will initiate sensitivity testing if indicated by test results. Sensitivity testing identifies the antibiotics to which the organisms are susceptible to ensure an effective treatment plan.

Commonly detected organisms are those normally found in the genitourinary tract, including gram negative *Enterococci*, *Escherichia coli*, *Klebsiella*, *Proteus*, and *Pseudomonas*. A culture showing multiple organisms indicates a contaminated specimen.

Colony counts of 100,000/mL or more indicate urinary tract infection (UTI).

Colony counts of 1,000/mL or less suggest contamination resulting from poor collection technique.

Colony counts between 1,000 and 10,000/mL may be significant depending on a variety of factors, including patient's age, gender, number of types of organisms present, method of specimen collection, and presence of antibiotics.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of suspected UTI
- Determine the sensitivity of significant organisms to antibiotics
- Monitor the response to UTI treatment

POTENTIAL DIAGNOSIS

Positive findings in

- UTIs

Negative findings in: N/A

CRITICAL FINDINGS

- Gram negative extended spectrum beta lactamases (ESBL) *E. coli* or *Klebsiella*
- Gram negative *Legionella*
- Gram positive Vancomycin-resistant *Enterococci* (VRE)

Note and immediately report to the health-care provider (HCP) positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). Lists of specific organisms may vary among facilities; specific organisms are required to be reported to local, state, and national departments of health.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Antibiotic therapy initiated before specimen collection may produce false-negative results.
- Improper collection techniques may result in specimen contamination.
- Specimen storage for longer than 2 hr at room temperature or 24 hr

at refrigerated temperature may result in overgrowth of bacteria and false-positive results. Such specimens may be rejected for analysis.

- Results of urine culture are often interpreted along with routine urinalysis findings.
- Discrepancies between culture and urinalysis may be reason to re-collect the specimen.
- Specimens submitted in expired urine transport tubes will be rejected for analysis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent medications that can interfere with test results.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there should be no discomfort during the specimen collection. Inform the patient that specimen collection depends on patient cooperation and usually takes approximately 5 to 10 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions, unless by medical direction.

- ▶ Instruct the patient on clean-catch procedure and provide necessary supplies.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with medication restrictions prior to the procedure.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, method of specimen collection, and any medications the patient has taken that may interfere with test results (e.g., antibiotics).
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Pediatric Urine Collector

- ▶ Put on gloves. Appropriately cleanse the genital area, and allow the area to dry. Remove the covering over the adhesive strips on the collector bag and apply over the genital area. Diaper the child. When specimen is obtained, place the entire collection bag in a sterile urine container.

Indwelling Catheter

- ▶ Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to

25-gauge needle and syringe. Transfer urine to a sterile container.

Urinary Catheterization

- ▶ Place female patient in lithotomy position or male patient in supine position. Using sterile technique, open the straight urinary catheterization kit and perform urinary catheterization. Place the retained urine in a sterile specimen container.

Suprapubic Aspiration

- ▶ Place the patient in supine position. Cleanse the area with antiseptic, and drape with sterile drapes. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container.
- ▶ Do not collect urine from the pouch from a patient with a urinary diversion (e.g., ileal conduit). Instead, perform catheterization through the stoma.

General

- ▶ Promptly transport the specimen to the laboratory for processing and analysis. If a delay in transport is expected, an aliquot of the specimen into a special tube containing a preservative is recommended. Urine transport tubes can be requested from the laboratory.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medication as directed by the HCP.
- ▶ Instruct the patient to report symptoms such as pain related to tissue inflammation, pain or irritation during void, bladder spasms, or alterations in urinary elimination.
- ▶ Observe for signs of inflammation if the specimen is obtained by suprapubic aspiration.
- ▶ Administer antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ **Nutritional Considerations:** Instruct the patient to increase water consumption

by drinking 8 to 12 glasses of water to assist in flushing the urinary tract. Instruct the patient to avoid alcohol, caffeine, and carbonated beverages, which can cause bladder irritation.

- ▶ Prevention of UTIs includes increasing daily water consumption, urinating when urge occurs, wiping the perineal area from front to back after urination/defecation, and urinating immediately after intercourse. Prevention also includes maintaining the normal flora of the body. Patients should avoid using spermicidal creams with diaphragms or condoms (when recommended by an HCP), becoming constipated, douching, taking bubble baths, wearing tight-fitting garments, and using deodorizing feminine hygiene products that alter the body's normal flora and increase susceptibility to UTIs.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Emphasize the importance of reporting continued signs and symptoms of the infection. Instruct patient on the proper technique for wiping the perineal area (front to back) after a bowel movement. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CBC, CBC WBC count and differential, cystometry, cystoscopy, cystourethrography voiding, cytology urine, Gram stain, renogram, and UA.
- ▶ Refer to the Genitourinary and Immune systems tables at the end of the book for related tests by body system.

Culture, Fungal

SYNONYM/ACRONYM: N/A.

COMMON USE: To identify the pathogenic fungal organisms causing infection.

SPECIMEN: Hair, skin, nail, pus, sterile fluids, blood, bone marrow, stool, bronchial washings, sputum, or tissue samples collected in a sterile plastic, tightly capped container.

NORMAL FINDINGS: (Method: Culture on selective media; macroscopic and microscopic examination) No presence of fungi.

DESCRIPTION: Fungi, organisms that normally live in soil, can be introduced into humans through the accidental inhalation of spores or inoculation of spores into tissue through trauma. Individuals most susceptible to fungal infection usually are debilitated by chronic disease, are receiving prolonged antibiotic therapy, or have impaired immune systems. Fungal diseases may be classified according to the involved tissue type: dermatophytoses involve superficial and cutaneous tissue; there are also subcutaneous and systemic mycoses.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine antimicrobial sensitivity of the organism
- Isolate and identify organisms responsible for neonatal thrush
- Isolate and identify organisms responsible for nail infections or abnormalities
- Isolate and identify organisms responsible for skin eruptions, drainage, or other evidence of infection

POTENTIAL DIAGNOSIS

Positive findings in

- Blood
 - Candida albicans*
 - Histoplasma capsulatum*
- Cerebrospinal fluid
 - Coccidioides immitis*
 - Cryptococcus neoformans*
 - Members of the order *Mucorales*
 - Paracoccidioides brasiliensis*
 - Sporothrix schenckii*
- Hair
 - Epidermophyton*
 - Microsporum*
 - Trichophyton*
- Nails
 - C. albicans*
 - Cephalosporium*
 - Epidermophyton*
 - Trichophyton*
- Skin
 - Actinomyces israelii*
 - C. albicans*
 - C. immitis*
 - Epidermophyton*
 - Microsporum*
 - Trichophyton*
- Tissue
 - A. israelii*
 - Aspergillus*
 - C. albicans*
 - Nocardia*
 - P. brasiliensis*

CRITICAL FINDINGS

- Positive findings in any sterile body fluid such as blood or cerebrospinal fluid.

Note and immediately report to the health-care provider (HCP) positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). Lists of specific organisms may vary among facilities; specific organisms are required to be reported to local, state, and national departments of health.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens.
- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent medications that can interfere with test results.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 min. Address concerns about pain and explain that there may be some discomfort during the specimen collection.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Instructions regarding the appropriate transport materials for blood, bone marrow, bronchial washings, sputum, sterile fluids, stool, and tissue samples should be obtained from the laboratory. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

Skin

- ▶ Clean the collection site with 70% alcohol. Scrape the peripheral margin of the collection site with a sterile scalpel or wooden spatula. Place the scrapings in a sterile collection container.

Hair

- ▶ Fungi usually grow at the base of the hair shaft. Infected hairs can be identified by using a Wood's lamp in a darkened room. A Wood's lamp provides rays of ultraviolet light at a wavelength of 366 nm, or 3,660 Å. Infected hairs fluoresce a bright yellow-green when exposed to light from the Wood's lamp. Using tweezers, pluck hair from skin.

Nails

- ▶ Ideally, softened material from the nailbed is sampled from beneath the nail plate. Alternatively, shavings from the deeper portions of the nail itself can be collected.
- ▶ Results of a conventional fungal culture may take up to 4 wk. Results of fungal antibody tests are available within a few days of collection and may be ordered when there is a strong suspicion of a particular pathogen. Most often, results indicating the presence or absence of fungi can be obtained in moments by looking at small amounts of the specimen under a microscope. A portion of the sample or swab is placed in sterile saline, and a drop from the diluted sample is placed on a glass slide, also called a wet prep. Another portion of the sample or a second swab is mixed with 15% potassium hydroxide (KOH), and a drop from the KOH sample is placed on a glass slide. A coverslip is placed over each specimen on the slide. The slides are examined under a microscope for the presence of fungal elements: mycelium, mycelial fragments, spores, or budding yeast cells. The KOH test is used in conjunction with the wet prep because the KOH destroys bacterial and epithelial cells while leaving fungal elements clearly visible, if present.

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Emphasize the importance of reporting continued signs and symptoms of the infection. Answer any questions or address any concerns voiced by the patient or family. Educate the adult patient regarding good oral and personal hygiene. Educate the parents or caregivers of infants or children with thrush (oral *Candida* infection) regarding the mechanism for transmission of the infection; stress the importance of keeping bottle-feeding equipment (especially nipples), pacifiers, and toys, cleaned and disinfected or sterilized, as appropriate, on a regular basis. Stress the importance of good hand hygiene for all who come in contact with the infant/child whose immune system is still developing and may be at higher risk for infection. Diaper rash or diaper Candidiasis may be instigated by changes in diet or frequent stools that affect the integrity of the infant or child's delicate skin and allow an opportunity for infection to occur. Discuss the importance of frequent diaper changes and proper cleansing of the genital area with the parents or caregivers of infants or children with diaper rash.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct patient to begin antifungal therapy, as prescribed. Instruct the patient in the importance of completing the entire course of antifungal therapy even if no symptoms are present.

RELATED MONOGRAPHS:

- ▶ Related tests include relevant biopsies (lung, lymph node, skin), bronchoscopy, cultures (blood, mycobacteria, throat, sputum, viral), CSF analysis, gallium scan, HIV-1/2 antibodies, pulmonary function tests, and TB tests.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Culture, Viral

SYNONYM/ACRONYM: N/A.

COMMON USE: To identify infection caused by pathogenic viral organisms as evidenced by ocular, genitourinary, intestinal, or respiratory symptoms. Commonly identified are cytomegalovirus (CMV), Epstein-Barr virus, herpes simplex virus (HSV), HIV, human papillomavirus (HPV), respiratory syncytial virus (RSV), and varicella zoster virus.

SPECIMEN: Urine, semen, blood, body fluid, stool, tissue, or swabs from the affected site.

NORMAL FINDINGS: (Method: Culture in special media, enzyme-linked immunoassays, direct fluorescent antibody techniques, latex agglutination, immunoperoxidase, PCR techniques) No virus isolated.

DESCRIPTION: Viruses, the most common cause of human infection, are submicroscopic organisms that invade living cells. They can be classified as either RNA- or DNA-type viruses. Viral titers are highest in the early stages of disease before the host has begun to manufacture significant antibodies against the invader. Specimens need to be collected as early as possible in the disease process. The subspecialty of microbiology has been revolutionized by molecular diagnostics. Molecular diagnostics involves the identification of specific sequences of DNA. The application of molecular diagnostics techniques, such as PCR, has led to the development of automated instruments that can identify a single infectious agent or multiple pathogens from a small amount of specimen in less than 2 hr. The instruments can detect the presence of bacteria and viruses commonly associated with viral infections.

This procedure is contraindicated for: N/A

INDICATIONS

Assist in the identification of viral infection

POTENTIAL DIAGNOSIS

Positive findings in

- AIDS
HIV
- Acute respiratory failure
Hantavirus
- Anorectal infections
HSV
HPV
- Bronchitis
Parainfluenza virus
RSV
- Cervical cancer
HPV
- Condylomata
HPV
- Conjunctivitis/keratitis

Influenza virus
Parainfluenza virus
RSV
Rhinovirus

CRITICAL FINDINGS

Positive RSV, influenza, and varicella zoster cultures should be reported immediately to the requesting health-care provider (HCP).

Note and immediately report to the HCP positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). Lists of specific organisms may vary among facilities; specific organisms are required to be reported to local, state, and national departments of health.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique

identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- **Viral specimens are unstable.** Prompt and proper specimen processing, storage, and analysis are important to achieve accurate results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal, genitourinary, immune, reproductive, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent medications that can interfere with test results.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 min. Address concerns about pain and explain that there may be some

discomfort during the specimen collection.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

INTRATEST:

Potential Complications: N/A

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, date and time of collection, exact site, contact person for notification of results, and other pertinent information (e.g., patient immunocompromised owing to organ transplant, radiation, or chemotherapy).
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instructions regarding the appropriate transport materials for blood, bronchial washings, sputum, sterile fluids, stool, and tissue samples should be obtained from the laboratory. The type of applicator used to obtain swabs should be verified by consultation with the testing laboratory personnel.
- ▶ The appropriate viral transport material should be obtained from the laboratory. Nasopharyngeal washings or swabs for RSV testing should be immediately placed in cold viral transport media.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Dehydration can be seen in patients with viral

infections due to loss of fluids through fever, diarrhea, and/or vomiting. Antipyretic medication includes acetaminophen to decrease fever and allow for adequate intake of fluids and foods. Do not give acetylsalicylic acid to pediatric patients with a viral illness because it increases the risk of Reye's syndrome.

▶ **Sensitivity to social and cultural issues:**

Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks of sexually transmitted diseases. It is also important to address problems the patient may experience (e.g., guilt, depression, anger).

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Provide information regarding vaccine-preventable diseases where indicated (e.g., encephalitis, H1N1 flu, seasonal influenza.). Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac). Answer any

questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include alveolar/arterial gradient, β -2-microglobulin, barium enema, biopsy (cervical, intestinal, kidney, liver, lung, lymph node, muscle, skin), blood gases, bronchoscopy, CD4/CD8 ratio, CSF analysis, *Chlamydia* group antibody, chest x-ray, cultures (anal, blood, ear, eye, fungal, genital, mycobacteria, skin, sputum, stool, throat, urine, wound), CBC, cytology (sputum, urine), gallium scan, gastric emptying scan, lung perfusion scan, lung ventilation scan, Pap smear, pericardial fluid analysis, plethysmography, pulse oximetry, PFT, slit-lamp biomicroscopy, syphilis serology, TB tests, and viral serology tests (hepatitis, HIV, HTLV, infectious mononucleosis, mumps, rubella, rubeola, varicella).
- ▶ Refer to the Gastrointestinal, Genitourinary, Immune, Reproductive, and Respiratory systems tables at the end of the book for related tests by body system.

Cystometry

SYNONYM/ACRONYM: CMG, urodynamic testing of bladder function.

COMMON USE: To assess bladder function related to obstruction, neurogenic pathology, and infection including evaluation of surgical, and medical management.

AREA OF APPLICATION: Bladder, urethra.

CONTRAST: None.

DESCRIPTION: Cystometry evaluates the motor and sensory function of the bladder when incontinence is present or neurological bladder dysfunction is suspected and monitors the effects of treatment for the abnormalities. This manometric study measures the bladder pressure and volume characteristics in milliliters of water (cm H₂O) during the filling and emptying phases. The test provides information about bladder structure and function that can lead to uninhibited bladder contractions, sensations of bladder fullness and need to void, and ability to inhibit voiding. These abnormalities cause incontinence and other impaired patterns of micturition. Cystometry can be performed with cystoscopy and electromyography pelvic floor sphincter.

A post-void residual measurement can also be done at the bedside to measure how much urine is left in the bladder after the patient voids. Completion of this test requires catheterization of the patient directly after voiding. The amount of urine remaining is measured and reported as the post-void or residual urine. Normal post-void residual is less than 50 mL of urine. This may be adjusted to less than 100 mL for those over the age of 65.

This procedure is contraindicated for

-  Patients with acute urinary tract infections (UTIs) because the study can cause infection to spread to the kidneys.
-  Patients with urethral obstruction.
-  Patients who are unable to be catheterized.

-  Patients with cervical cord lesions **because they may exhibit autonomic dysreflexia, as seen by bradycardia, flushing, hypertension, diaphoresis, and headache.**

INDICATIONS

- Detect congenital urinary abnormalities
- Determine cause of bladder dysfunction and pathology
- Determine cause of recurrent urinary tract infections (UTIs)
- Determine cause of urinary retention
- Determine type of incontinence: *functional* (involuntary and unpredictable), *reflex* (involuntary when a specific volume is reached), *stress* (weak pelvic muscles), *total* (continuous and unpredictable), *urge* (involuntary when urgency is sensed), and *psychological* (e.g., dementia, confusion affecting awareness)
- Determine type of neurogenic bladder (motor or sensory)
- Evaluate the management of neurological bladder before surgical intervention
- Evaluate postprostatectomy incontinence
- Evaluate signs and symptoms of urinary elimination pattern dysfunction
- Evaluate urinary obstruction in male patients experiencing urinary retention
- Evaluate the usefulness of drug therapy on detrusor muscle function and tonicity and on internal and external sphincter function
- Evaluate voiding disorders associated with spinal cord injury

POTENTIAL DIAGNOSIS

Normal findings in

- Amount of post-void residual urine is less than 50 mL

- Normal sensory perception of bladder fullness, desire to void, and ability to inhibit urination; appropriate response to temperature (hot and cold)
- Normal bladder capacity: 350 to 750 mL for men and 250 to 550 mL for women
- Normal functioning bladder pressure: 8 to 15 cm H₂O
- Normal sensation of fullness: 40 to 100 cm H₂O or 300 to 500 mL
- Normal bladder pressure during voiding: 30 to 40 cm H₂O
- Normal detrusor pressure: less than 10 cm H₂O
- Normal urge to void: 150 to 450 mL
- Normal filling pattern
- Urethral pressure that is higher than bladder pressure, ensuring continence

Abnormal findings in

- Flaccid bladder that fills without contracting
- Inability to perceive bladder fullness
- Inability to initiate or maintain urination without applying external pressure
- Sensory or motor paralysis of bladder indicated by reduced filling pressures
- Total loss of conscious sensation and vesical control or uncontrollable micturition (incontinence)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Inability of the patient to void in a supine position or straining to void during the study.

- A high level of patient anxiety or embarrassment, which may interfere with the study, making it difficult to distinguish whether the results are due to stress or organic pathology.
- Administration of drugs that affect bladder function, such as muscle relaxants or antihistamines.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing bladder function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or medications that may be used during the procedure.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is performed in a special urology room or in a clinic setting by the health-care provider (HCP), with support staff, and takes approximately 30 to 45 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Instruct the patient to report pain, sweating, nausea, headache, and the urge to void during the study.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

UTI *related to use of a catheter*

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to change into the gown, robe, and foot coverings provided, but not to void.
- ▶ Position the patient in a supine or lithotomy position on the examination table. If spinal cord injury is present, the patient can remain on a stretcher in a supine position and be draped appropriately.
- ▶ Ask the patient to void. During voiding, note characteristics such as start time; force and continuity of the stream; volume voided; presence of dribbling, straining, or hesitancy; and stop time.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still during the procedure.
- ▶ A urinary catheter is inserted into the bladder under sterile conditions, and residual urine is measured and recorded. A test for sensory response to temperature is done by instilling 30 mL of room-temperature sterile water followed by 30 mL of warm sterile water. Sensations are assessed and recorded.
- ▶ Fluid is removed from the bladder, and the catheter is connected to a cystometer that measures the pressure. Sterile normal saline, distilled water, or carbon dioxide gas is instilled in controlled amounts into the bladder. When

the patient indicates the urge to void, the bladder is considered full. The patient is instructed to void, and urination amounts as well as start and stop times are then recorded.

- ▶ Pressure and volume readings are recorded and graphed for response to heat, full bladder, urge to void, and ability to inhibit voiding. The patient is requested to void without straining, and pressures are taken and recorded during this activity.
- ▶ After completion of voiding, the bladder is emptied of any other fluid, and the catheter is withdrawn, unless further testing is planned.
- ▶ Further testing may be done to determine if abnormal bladder function is being caused by muscle incompetence or interruption in innervation; anticholinergic medication (e.g., atropine) or cholinergic medication (e.g., bethanechol [Urecholine]) can be injected and the study repeated in 20 or 30 min.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Monitor fluid intake and urinary output for 24 hr after the procedure.
- ▶ Monitor vital signs after the procedure every 15 min for 2 hr or as directed. Monitor intake and output at least every 8 hr. Elevated temperature may indicate infection. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Inform the patient that he or she may experience burning or discomfort on urination for a few voidings after the procedure.
- ▶ Persistent flank or suprapubic pain, fever, chills, blood in the urine, difficulty urinating, or change in urinary pattern must be reported immediately to the HCP.

- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of

the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include bladder cancer markers, calculus kidney stone panel, *Chlamydia* group antibody, CBC, CBC hematocrit, CBC hemoglobin, CT pelvis, culture urine, cytology urine, IVP, MRI pelvis, PT/INR, US pelvis, and UA.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Cystoscopy

SYNONYM/ACRONYM: Cystoureterography, prostaticography.

COMMON USE: To assess the urinary tract for bleeding, cancer, tumor, and prostate health.

AREA OF APPLICATION: Bladder, urethra, ureteral orifices.

CONTRAST: None.

DESCRIPTION: Cystoscopy provides direct visualization of the urethra, urinary bladder, and ureteral orifices—areas not usually visible with x-ray procedures. This procedure is also used to obtain specimens and treat pathology associated with the aforementioned structures. Cystoscopy is accomplished by transurethral insertion of a cystoscope into the bladder. Rigid cystoscopes contain an obturator and a telescope with a lens and light system; there are also flexible cystoscopes, which use fiberoptic technology. The procedure may be performed during or

after ultrasonography or radiography, or during urethroscopy or retrograde pyelography.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients with bleeding disorders ***because instrumentation may lead to excessive bleeding from the lower urinary tract.***
-  Patients with acute cystitis or urethritis ***because***

instrumentation could allow bacteria to enter the bloodstream, resulting in septicemia.

INDICATIONS

- Coagulate bleeding areas
- Determine the possible source of persistent urinary tract infections
- Determine the source of hematuria of unknown cause
- Differentiate, through tissue biopsy, between benign and cancerous lesions involving the bladder
- Dilate the urethra and ureters
- Evacuate blood clots and perform fulguration of bleeding sites within the lower urinary tract
- Evaluate changes in urinary elimination patterns
- Evaluate the extent of prostatic hyperplasia and degree of obstruction
- Evaluate the function of each kidney by obtaining urine samples via ureteral catheters
- Evaluate urinary tract abnormalities such as dysuria, frequency, retention, inadequate stream, urgency, and incontinence
- Identify and remove polyps and small tumors (including by fulguration) from the bladder
- Identify congenital anomalies, such as duplicate ureters, ureteroceles, urethral or ureteral strictures, diverticula, and areas of inflammation or ulceration
- Implant radioactive seeds
- Place ureteral catheters to drain urine from the renal pelvis or for retrograde pyelography
- Place ureteral stents and resect prostate gland tissue (transurethral resection of the prostate)
- Remove renal calculi from the bladder or ureters
- Resect small tumors

POTENTIAL DIAGNOSIS

Normal findings in

- Normal ureter, bladder, and urethral structure

Abnormal findings in

- Diverticulum of the bladder, fistula, stones, and strictures
- Inflammation or infection
- Obstruction
- Polyps
- Prostatic hypertrophy or hyperplasia
- Renal calculi
- Tumors
- Ureteral or urethral stricture
- Urinary tract malformation and congenital anomalies

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the urinary tract.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, contrast medium, anesthetics, and dyes.
