- ▶ Obtain a history of results of the patient's genitourinary system, symptoms, and previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in a special cystoscopy suite near or in the surgery department by a health-care provider (HCP), with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ Obtain and record the patient's vital signs.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Infection **related to the use of the endoscope** or bleeding

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Ensure that the patient has complied with dietary restrictions; ensure that food has been restricted for at least 8 hr depending on the anesthetic chosen for the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, or emergency medications.
- ▶ Administer ordered preoperative sedation.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Position patient on the examination table, draped and with legs in stirrups. If general or spinal anesthesia is to be used, it is administered before positioning the patient on the table.
- ▶ Cleanse external genitalia with antiseptic solution. If local anesthetic is used, it is instilled into the urethra and retained for 5 to 10 min. A penile clamp may be used for male patients to aid in retention of anesthetic.
- ▶ The HCP inserts a cystoscope or a urethroscope to examine the urethra

before cystoscopy. The urethroscope has a sheath that may be left in place, and the cystoscope is inserted through it, avoiding multiple instrumentations.

- ▶ After insertion of the cystoscope, a sample of residual urine may be obtained for culture or other analysis.
- ▶ The bladder is irrigated via an irrigation system attached to the scope. The irrigation fluid aids in bladder visualization.
- ▶ If a prostatic tumor is found, a biopsy specimen may be obtained by means of a cytology brush or biopsy forceps inserted through the scope. If the tumor is small and localized, it can be excised and fulgurated. This procedure is termed transurethral resection of the bladder. Polyps can also be identified and excised.
- ▶ Ulcers or bleeding sites can be fulgurated using electrocautery.
- ▶ Renal calculi can be crushed and removed from the ureters and bladder.
- ▶ Ureteral catheters can be inserted via the scope to obtain urine samples from each kidney for comparative analysis and radiographic studies.
- ▶ Ureteral and urethral strictures can also be dilated during this procedure.
- ▶ Upon completion of the examination and related procedures, the cystoscope is withdrawn.
- ▶ Place obtained specimens in proper containers, label them properly, and immediately transport them to the laboratory.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume his or her usual diet and medications, as directed by the HCP.
- ▶ Encourage the patient to drink increased amounts of fluids (125 mL/hr for 24 hr) after the procedure.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take the temperature every 4 hr for 24 hr. Monitor

intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Inform the patient that burning or discomfort on urination can be experienced for a few voidings after the procedure and that the urine may be blood-tinged for the first and second voidings after the procedure.
- ▶ Persistent flank or suprapubic pain, fever, chills, blood in the urine, difficulty urinating, or change in urinary pattern must be reported immediately to the HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy kidney, biopsy prostate, calculus kidney stone panel, *Chlamydia* group antibody, CT pelvis, culture urine, cytology urine, IVP, MRI pelvis, PSA, US pelvis, and UA.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Cystourethrography, Voiding

SYNONYM/ACRONYM: Voiding cystourethrography (VCU), voiding cystourethrogram (VCUG), micturating cystourethrogram (MCUG).

COMMON USE: To visualize and assess the bladder during voiding for evaluation of chronic urinary tract infections.

AREA OF APPLICATION: Bladder, urethra.

CONTRAST: Radiopaque iodine-based contrast medium.

DESCRIPTION: Voiding cystourethrography involves visualization of the bladder filled with contrast medium instilled through a catheter by use of a syringe or gravity, and, after the catheter is removed, the excretion of the contrast medium. Excretion or micturition is recorded electronically or on videotape for confirmation or exclusion of ureteral reflux and evaluation of the urethra. Fluoroscopic or plain images may also be taken to record bladder filling and emptying. This procedure is often used to evaluate chronic urinary tract infections (UTIs).

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is

not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
- ◆ Patients with bleeding disorders **because the puncture site may not stop bleeding.**

-  Patients with an active urinary tract infection, obstruction, or injury.

INDICATIONS

- Assess the degree of compromise of a stenotic prostatic urethra
- Assess hypertrophy of the prostate lobes
- Assess ureteral stricture
- Confirm the diagnosis of congenital lower urinary tract anomaly
- Evaluate abnormal bladder emptying and incontinence
- Evaluate the effects of bladder trauma
- Evaluate possible cause of frequent UTIs
- Evaluate the presence and extent of ureteral reflux
- Evaluate the urethra for obstruction and strictures

POTENTIAL DIAGNOSIS

Normal findings in

- Normal bladder and urethra structure and function

Abnormal findings in

- Bladder trauma
- Bladder tumors
- Hematomas
- Neurogenic bladder
- Pelvic tumors
- Prostatic enlargement
- Ureteral stricture
- Ureterocele
- Urethral diverticula
- Vesicoureteral reflux

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects within the examination field, which may inhibit organ visualization and cause unclear images.

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Pediatric & Geriatric Imaging**
Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.
- Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- **Patient Teaching:** Inform the patient this procedure can assist in assessing the urinary tract.
- Obtain a history of the patient's complaints or clinical symptoms, including

a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.

- ▶ Obtain a history of results of the patient's genitourinary system, symptoms, and previously performed laboratory tests and diagnostic and surgical procedures. Ensure that the results of blood tests are obtained and recorded before the procedure, especially coagulation tests, BUN, and creatinine if contrast medium is to be used.
- ▶ Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is usually performed in the radiology department by an HCP, with support staff, and takes approximately 30 to 60 min. Pediatric Considerations There is no specific pediatric patient preparation for cystourethrography. Encourage parents to be truthful about

unpleasant sensations (pinching or pushing) the child may experience during catheter insertion and to use words that they know their child will understand. Toddlers and preschool-age children have a very short attention span, so the best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with the child during the procedure. Infants and small children may be wrapped tightly in a blanket to assist in keeping them still during the procedure.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Inform the patient that he or she may receive a laxative the night before the test or an enema or a cathartic the morning of the test, as ordered.
- ▶ Instruct the patient to increase fluid intake the day before the test and to have only clear fluids 8 hr before the test.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Complications include dysuria, injury to the urethra, and urinary infection **related to use of a catheter**. Allergic reaction to contrast media is another potential complication.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure that the patient has complied with dietary restrictions. Assess for completion of bowel preparation if ordered.
 - ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
 - ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of

allergic reactions to any substance or drug.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Insert a Foley catheter before the procedure, if ordered. Inform the patient that he or she may feel some pressure when the catheter is inserted and when the contrast medium is instilled through the catheter.
- ▶ Place the patient on the table in a supine or lithotomy position.
- ▶ A kidney, ureter, and bladder radiograph (KUB) is taken to ensure that no barium or stool obscures visualization of the urinary system.
- ▶ A catheter is filled with contrast medium to eliminate air pockets and is inserted until the balloon reaches the meatus if not previously inserted in the patient.
- ▶ When three-fourths of the contrast medium has been injected, a radiographic exposure is made while the remainder of the contrast medium is injected.
- ▶ When the patient is able to void, the catheter is removed and the patient is asked to urinate while images of the bladder and urethra are recorded.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet and medications, as directed by the HCP.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by

the HCP. Take the temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ Monitor for reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Maintain the patient on adequate hydration after the procedure. Encourage the patient to drink increased amounts of fluids (125 mL/hr for 24 hr) after the procedure to prevent stasis and bacterial buildup.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy prostate, bladder cancer markers, BUN, CT pelvis, creatinine cytology urine, IVP, MRI pelvis, PSA, PT/INR, and US pelvis.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Cytology, Sputum

SYNONYM/ACRONYM: N/A.

COMMON USE: To identify cellular changes associated with neoplasms or organisms that result in respiratory tract infections, such as *Pneumocystis jiroveci* (formerly *P. carinii*).

SPECIMEN: Sputum (10 to 15 mL) collected on three to five consecutive first-morning, deep-cough expectorations.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination) Negative for abnormal cells, fungi, ova, and parasites.

DESCRIPTION: Cytology is the study of the origin, structure, function, and pathology of cells. In clinical practice, cytological examinations are generally performed to detect cell changes resulting from neoplastic or inflammatory conditions. Sputum specimens for cytological examinations may be collected by expectoration alone, by suctioning, by lung biopsy, during bronchoscopy, or by expectoration after bronchoscopy. A description of the method of specimen collection by bronchoscopy and biopsy is found in the monograph titled “Biopsy, Lung.”

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of lung cancer
- Assist in the identification of *Pneumocystis jiroveci* (formerly *P. carinii*) in persons with AIDS
- Detect known or suspected fungal or parasitic infection involving the lung
- Detect known or suspected viral disease involving the lung

- Screen cigarette smokers for neoplastic (nonmalignant) cellular changes
- Screen patients with history of acute or chronic inflammatory or infectious lung disorders, which may lead to benign atypical or metaplastic changes

POTENTIAL DIAGNOSIS

(Method: Microscopic examination) The method of reporting results of cytology examinations varies according to the laboratory performing the test. Terms used to report results may include *negative* (no abnormal cells seen), *inflammatory*, *benign atypical*, *suspect for neoplasm*, and *positive for neoplasm*.

Positive findings in

- Infections caused by fungi, ova, or parasites
- Lipoid or aspiration pneumonia, as seen by lipid droplets contained in macrophages
- Neoplasms
- Viral infections and lung disease

CRITICAL FINDINGS

- Identification of malignancy

Note and immediately report to the health-care provider (HCP) positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the

requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

If the patient becomes hypoxic or cyanotic, remove catheter immediately and administer oxygen.

If patient has asthma or chronic bronchitis, watch for aggravated bronchospasms with use of normal saline or acetylcysteine in an aerosol.

INTERFERING FACTORS

- Improper specimen fixation may be cause for specimen rejection.
- Improper technique used to obtain bronchial washing may be cause for specimen rejection.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before

providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Review the procedure with the patient. If the laboratory has provided a container with fixative, instruct the patient that the fixative contents of the specimen collection container should not be ingested or otherwise removed. Instruct the patient not to touch the edge or inside of the specimen container with the hands or mouth. Inform the patient that three samples may be required, on three separate mornings, either by passing a small tube (tracheal catheter) and adding suction or by expectoration. The time it takes to collect a proper specimen varies according to the level of cooperation of the patient and the specimen collection procedure. Address concerns about pain related to the procedure. Atropine is usually given before bronchoscopy examinations to reduce bronchial secretions and to prevent vagally induced bradycardia. Meperidine (Demerol) or morphine may be given as a sedative. Lidocaine is sprayed in the patient's throat to reduce discomfort caused by the presence of the tube.
- ▶ Reassure the patient that he or she will be able to breathe during the procedure if specimen is collected via suction method. Ensure that oxygen has been administered 20 to 30 min before the procedure if the specimen is to be obtained by tracheal suctioning.

- ▶ Assist in providing extra fluids, unless contraindicated, and proper humidification to loosen tenacious secretions. Inform the patient that increasing fluid intake before retiring on the night before the test aids in liquefying secretions and may make it easier to expectorate in the morning. Also explain that humidifying inspired air also helps to liquefy secretions.
- ▶ Assist with mouth care (brushing teeth or rinsing mouth with water), if needed, before collection so as not to contaminate the specimen by oral secretions.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- ▶ For specimens collected by suctioning or expectoration without bronchoscopy, there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Instruct the patient to fast and refrain from taking liquids from midnight the night before if bronchoscopy or biopsy is to be performed. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the bronchoscopy or biopsy procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Bleeding (**related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**), bronchospasm, pneumothorax, or hemoptysis.

- ▶ Ensure that the patient has complied with dietary restrictions; assure that food and liquids have been restricted for at least 6 to 8 hr prior to the procedure.
- ▶ Have patient remove dentures, contact lenses, eyeglasses, and jewelry. Notify the HCP if the patient has permanent crowns on teeth. Have the patient remove clothing and change into a gown for the procedure.
- ▶ Have emergency equipment readily available. Keep resuscitation

equipment on hand in the case of respiratory impairment or laryngospasm after the procedure.

- ▶ Avoid using morphine sulfate in those with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Assist the patient to a comfortable position, and direct the patient to breathe normally during the beginning of the general anesthesia and to avoid unnecessary movement during the local anesthetic and the procedure. Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, date and time of collection, and any medication the patient is taking that may interfere with test results (e.g., antibiotics). Cytology specimens may also be expressed onto a glass slide and sprayed with a fixative or 95% alcohol.

Bronchoscopy

- ▶ Record baseline vital signs.
- ▶ The patient is positioned in relation to the type of anesthesia being used. If local anesthesia is used, the patient is seated, and the tongue and oropharynx are sprayed and swabbed with anesthetic before the bronchoscope is inserted. For general anesthesia, the patient is placed in a supine position with the neck hyperextended. After anesthesia, the patient is kept in supine or shifted to side-lying position, and the bronchoscope is inserted. After inspection, the samples are collected from suspicious sites by bronchial brush or biopsy forceps.

Expectorated Specimen

- ▶ Ask the patient to sit upright, with assistance and support (e.g., with an overbed table) as needed.

- ▶ Ask the patient to take two or three deep breaths and cough deeply. Any sputum raised should be expectorated directly into a sterile sputum collection container.
- ▶ If the patient is unable to produce the desired amount of sputum, several strategies may be attempted. One approach is to have the patient drink two glasses of water, and then assume the position for postural drainage of the upper and middle lung segments. Effective coughing may be assisted by placing either the hands or a pillow over the diaphragmatic area and applying slight pressure.
- ▶ Another approach is to place a vaporizer or other humidifying device at the bedside. After sufficient exposure to adequate humidification, postural drainage of the upper and middle lung segments may be repeated before attempting to obtain the specimen.
- ▶ Other methods may include obtaining an order for an expectorant to be administered with additional water approximately 2 hr before attempting to obtain the specimen. Chest percussion and postural drainage of all lung segments may also be employed. If the patient is still unable to raise sputum, the use of an ultrasonic nebulizer (“induced sputum”) may be necessary; this is usually done by a respiratory therapist.

Tracheal Suctioning

- ▶ Obtain the necessary equipment, including a suction device, suction kit, and Lukens tube or in-line trap.
- ▶ Position the patient with head elevated as high as tolerated.
- ▶ Put on sterile gloves. Maintain the dominant hand as sterile and the nondominant hand as clean.
- ▶ Using the sterile hand, attach the suction catheter to the rubber tubing of the Lukens tube or in-line trap. Then attach the suction tubing to the male adapter of the trap with the clean hand. Lubricate the suction catheter with sterile saline.
- ▶ Tell nonintubated patients to protrude the tongue and to take a deep breath

as the suction catheter is passed through the nostril. When the catheter enters the trachea, a reflex cough is stimulated; immediately advance the catheter into the trachea and apply suction. Maintain suction for approximately 10 sec, but never longer than 15 sec. Withdraw the catheter without applying suction. Separate the suction catheter and suction tubing from the trap, and place the rubber tubing over the male adapter to seal the unit.

- ▶ For intubated patients or patients with a tracheostomy, the previous procedure is followed except that the suction catheter is passed through the existing endotracheal or tracheostomy tube rather than through the nostril. The patient should be hyperoxygenated before and after the procedure in accordance with standard protocols for suctioning these patients.
- ▶ Generally, a series of three to five early-morning sputum samples are collected in sterile containers.

General

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, as directed by the HCP. Assess the patient's ability to swallow before allowing the patient to attempt liquids or solid foods.
- ▶ Inform the patient that he or she may experience some throat soreness and hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.
- ▶ Monitor vital signs and compare with baseline values every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr.

Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ Emergency resuscitation equipment should be readily available if the vocal cords become spastic after intubation.
- ▶ Observe/assess for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the patient for hemoptysis, difficulty breathing, cough, air hunger, excessive coughing, pain, or absent breathing sounds over the affected area. Report any symptoms to the HCP.
- ▶ Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. A chest x-ray may be ordered to check for the presence of this complication.
- ▶ Evaluate the patient for symptoms of empyema, such as fever, tachycardia, malaise, or elevated white blood cell count.
- ▶ Administer antibiotic therapy if ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if signs and symptoms disappear before completion of therapy.
- ▶ **Nutritional Considerations:** Malnutrition is commonly seen in patients with severe respiratory disease for numerous reasons including fatigue, lack of appetite, and gastrointestinal distress. Adequate intake of vitamins A and C are also important to prevent pulmonary infection and to decrease the extent of lung tissue damage.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient

regarding access to counseling services. Provide contact information, if desired, for the American Lung Association (www.lungusa.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient of smoking cessation programs, as appropriate. Inform the patient with abnormal findings of the importance of medical follow-up, and suggest ongoing support resources to assist in coping with chronic illness and possible early death. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include arterial/alveolar oxygen ratio, biopsy lung, blood gases, bronchoscopy, CBC, CT thoracic, relevant cultures (fungal, mycobacteria, sputum, throat, viral), gallium scan, Gram/acid-fast stain, lung perfusion scan, lung ventilation scan, MRI chest, mediastinoscopy, pleural fluid analysis, pulmonary function tests, and TB tests.
- ▶ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Cytology, Urine

SYNONYM/ACRONYM: N/A.

COMMON USE: To identify the presence of neoplasms of the urinary tract and assist in the diagnosis of urinary tract infections.

SPECIMEN: Urine (180 mL for an adult; at least 10 mL for a child) collected in a clean wide-mouth plastic container.

NORMAL FINDINGS: (Method: Microscopic examination) No abnormal cells or inclusions seen.

DESCRIPTION: Cytology is the study of the origin, structure, function, and pathology of cells. In clinical practice, cytological examinations are generally performed to detect cell changes resulting from neoplastic or inflammatory conditions. Cells from the epithelial lining of the urinary tract can be found in the urine. Examination of these cells for abnormalities is useful with suspected infection, inflammatory conditions, or malignancy.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of urinary tract diseases, such as cancer, cytomegalovirus infection, and other inflammatory conditions

POTENTIAL DIAGNOSIS

Positive findings in

- Cancer of the urinary tract
- Cytomegalic inclusion disease
- Inflammatory disease of the urinary tract

Negative findings in: N/A

CRITICAL FINDINGS

- Identification of malignancy

Note and immediately report to the health-care provider (HCP) positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection or the presence of a tumor in the urinary tract.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Review the procedure with the patient. If a catheterized specimen is to be collected, explain this procedure to the patient and obtain a catheterization tray. Address concerns about pain and explain that there may be some discomfort during the catheterization.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate

tubes with the corresponding patient demographics, date and time of collection, method of specimen collection, and any medications the patient has taken that may interfere with test results (e.g., antibiotics).

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Pediatric Urine Collector

- ▶ Put on gloves. Appropriately cleanse the genital area, and allow the area to dry. Remove the covering over the adhesive strips on the collector bag and apply over the genital area. Diaper the child. After obtaining the specimen, place the entire collection bag in a sterile urine container.

Indwelling Catheter

- ▶ Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Urinary Catheterization

- ▶ Place female patient in lithotomy position or male patient in supine position. Using sterile technique, open the straight urinary catheterization kit and perform urinary catheterization. Place the retained urine in a sterile specimen container.

Suprapubic Aspiration

- ▶ Place the patient in supine position. Cleanse the area with antiseptic, and drape with sterile drapes. A needle is inserted through the skin into the bladder. A syringe attached to the needle is used to aspirate the urine

sample. The needle is then removed and a sterile dressing is applied to the site. Place the sterile sample in a sterile specimen container.

- Do not collect urine from the pouch from a patient with a urinary diversion (e.g., ileal conduit). Instead perform catheterization through the stoma.

General

- Promptly transport the specimen to the laboratory for processing and analysis. If a delay in transport is expected, add an equal volume of 50% alcohol to the specimen as a preservative.

POST-TEST:

- Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- Instruct the patient to resume usual medication as directed by the HCP.
- Instruct the patient to report symptoms such as pain related to tissue inflammation, pain or irritation during void, bladder spasms, or alterations in urinary elimination.
- Observe for signs of inflammation if the specimen is obtained by suprapubic aspiration.
- Administer antibiotic therapy as ordered. Remind the patient of the importance of completing the entire course of antibiotic therapy, even if

signs and symptoms disappear before completion of therapy.

- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include biopsy kidney, bladder cancer markers, cystoscopy, CMV IgG and IgM, Pap smear, UA, and US bladder.
- Refer to the Genitourinary and Immune systems tables at the end of the book for related tests by body system.

Cytomegalovirus, Immunoglobulin G, and Immunoglobulin M

SYNONYM/ACRONYM: CMV.

COMMON USE: To assist in diagnosing cytomegalovirus infection.

SPECIMEN: Serum (1 mL) collected in a plain red-top tube.

NORMAL FINDINGS: (Method: Enzyme immunoassay)

	IgM & IgG	Interpretation
Negative	0.9 index or less	No significant level of detectable antibody
Indeterminate	0.91–1.09 index	Equivocal results; retest in 10–14 d
Positive	1.1 index or greater	Antibody detected; indicative of recent immunization, current or recent infection

DESCRIPTION: Cytomegalovirus (CMV) is a double-stranded DNA herpesvirus. The Centers for Disease Control and Prevention (CDC) estimates that 50% to 85% of adults are infected by age 40. The incubation period for primary infection is 4 to 8 wk. Transmission may occur by direct contact with oral, respiratory, or venereal secretions and excretions. CMV infection is of primary concern in pregnant or immunocompromised patients or patients who have recently received an organ transplant. Blood units are sometimes tested for the presence of CMV if patients in these high-risk categories are the transfusion recipients. CMV serology is part of the TORCH (*toxoplasmosis, other* [congenital syphilis and viruses], *rubella, CMV, and herpes simplex type 2*) panel used to test pregnant women. CMV, as well as these other infectious agents, can cross the placenta and result in congenital malformations, abortion, or stillbirth. The presence of immunoglobulin (Ig) M antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. There are numerous methods for detection of CMV. The methodology selected is based on both the test purpose and specimen type. Other types of assays used to detect CMV include direct fluorescent assays used to identify CMV in tissue, sputum, and swab specimens; hemagglutination

assays, cleared by the FDA for testing blood prior to transfusion; polymerase chain reaction (PCR), used to test a wide variety of specimen types, including amniotic fluid, plasma, urine, CSF, and whole blood; and cell tissue culture, which remains the gold standard for the identification of CMV.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of congenital CMV infection in newborns
- Determine susceptibility, particularly in pregnant women, immunocompromised patients, and patients who recently have received an organ transplant
- Screen blood for high-risk-category transfusion recipients

POTENTIAL DIAGNOSIS

Positive findings in

- CMV infection

Negative findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- False-positive results may occur in the presence of rheumatoid factor.
- False-negative results may occur if treatment was begun before antibodies developed or if the test was done less than 6 days after exposure to the virus.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to viral infection secondary to blood transfusion; organ transplant; sexual contact; exposure to respiratory droplets</i>)	Fever, fatigue, loss of appetite; malaise; muscle aches; headache; irregular heartbeat; stiff neck; shortness of breath; swollen liver or spleen; tachycardia; rash; sore throat; increased blood pressure; elevated IgM, IgG	Promote good hygiene; assist with hygiene as needed; administer prescribed antivirals as appropriate, antipyretics; administer cooling measures; monitor vital signs and trend temperatures; encourage oral fluids; adhere to standard or universal precautions; provide isolation as appropriate; obtain cultures as ordered; assess nutritional status and provide supplements as needed
Fatigue (<i>Related to infection and inflammation</i>)	Report of tiredness; inability to maintain activities of daily living at current level; inability to restore energy after rest or sleep	Discuss the implementation of energy conservation activities (even pace when working, frequent rest periods, frequent items in easy reach, push items instead of pulling); limit naps to increase nighttime sleeping; set priorities for energy expenditures; administer ordered antibiotics
Sexuality (<i>Related to positive CMV [herpes virus]</i>)	Reduced sexual function; decreased sexual satisfaction; reports of alteration in relationship with partner	Assess perception of reported change in sexual function; assess emotional impact of herpes diagnosis (depression, altered self-esteem, altered personal relationships); assess need for counseling; encourage verbalization of feelings; discuss alternative forms of intimate expression; discuss medical treatments that may improve sexual interaction

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of the organism causing infection.

- ▶ Obtain a history of the patient's complaints and history of exposure. Obtain a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and reproductive systems, symptoms, and results of previously

performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that multiple specimens may be required. Any individual positive result should be repeated in 7 to 14 days to monitor a change in titer. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting health-care provider (HCP), who will discuss the results with the patient. Some HCPs may take additional precautions in the case of CMV antibody negative immunocompromised or pregnant patients by requesting CMV antibody negative blood products or organs in the event those interventions are required.

- ▶ Instruct the patient in isolation precautions during time of communicability or contagion.
- ▶ Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days.
- ▶ Warn the patient that there is a possibility of false-negative or false-positive results.
- ▶ Recognize anxiety related to test results if the patient is pregnant, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Provide emotional support if the patient is pregnant and if results are positive.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that it may take up to 6 wk for full recovery from the diagnosed viral infection

- States understanding that once CMV virus is in an individual, it will remain present for the rest of his or her life.
- States emergency response number and understands to call for severe abdominal pain that could indicate a ruptured spleen requiring emergency surgery.

Skills

- Demonstrates proficiency in using warm saltwater gargles for comfort with sore throat

Attitude

- Complies with the recommendation of infected persons to refrain from kissing

or other sexual contact to prevent infecting others

- Complies with the request to stay at home while infectious to avoid exposing others

RELATED MONOGRAPHS:

- Related tests include β_2 -microglobulin, bronchoscopy, *Chlamydia* group antibody, culture viral, cytology urine, HIV-1/2 antibodies, Pap smear, rubella antibody, and *Toxoplasma* antibody.
- Refer to the Immune and Reproductive systems tables at the end of the book for related tests by body system.

D-Dimer

SYNONYM/ACRONYM: Dimer, fibrin degradation fragment.

COMMON USE: To assist in diagnosing a diffuse state of hypercoagulation as seen in disseminated intravascular coagulation (DIC), acute myocardial infarction (MI), deep venous thrombosis (DVT), and pulmonary embolism (PE).

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Immunoturbidimetric)

Conventional Units (FEU = Fibrinogen Equivalent Units)	SI Units (Conventional Units × 5.476)
0–0.5 mcg/mL FEU	0–2.7 nmol/L

Levels increase with age.

DESCRIPTION: Activated Factor II or thrombin serves two functions. It helps convert fibrinogen to fibrin during the process of hemostasis and simultaneously activates the fibrinolytic system to provide a balance between blood clotting and vessel occlusion. D-dimers are crosslinked fragments of fibrin produced during fibrinolysis or dissolution of a clot. It is for this reason that increased D-dimers are utilized as an indication of the presence of a thrombus or clot. The test is not specific to the presence of a clot as other factors, to include infection, inflammation, and pregnancy can increase D-dimer concentration. A negative test can largely rule out presence of a new blood clot. A positive test is presumptive evidence of disseminated intravascular coagulation (DIC), deep vein thrombosis (DVT) or pulmonary embolism (PE) which must be confirmed using other tests. The D-dimer is specific to secondary fibrinolysis because it involves fibrin rather than fibrinogen. This

test may be used in combination with fibrinogen split or fibrinogen degradation products to differentiate primary fibrinolysis from secondary fibrinolysis. The treatment for primary fibrinolysis would require antifibrinolytic therapy while the treatment for secondary fibrinolysis (DIC) might include transfusion to replace consumed coagulation factors and platelets and anticoagulant therapy to prevent recurrent clot formation.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the detection of DIC and deep venous thrombosis (DVT)
- Assist in the evaluation of myocardial infarction (MI) and unstable angina
- Assist in the evaluation of possible veno-occlusive disease associated with sequelae of bone marrow transplant
- Assist in the evaluation of pulmonary embolism (PE)

POTENTIAL DIAGNOSIS

The sensitivity and specificity of the assay varies among test kits and between test methods.

Increased in

D-Dimers are formed in inflammatory conditions where plasmin carries out its fibrinolytic action on a fibrin clot.

- Arterial or venous thrombosis
- DVT
- DIC
- Neoplastic disease
- Pre-eclampsia
- Pregnancy (late and postpartum)
- PE
- Recent surgery (within 2 days)
- Secondary fibrinolysis
- Thrombolytic or fibrinolytic therapy

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- High rheumatoid factor titers can cause a false-positive result.
- Increased CA 125 levels can cause a false-positive result; patients with cancer may demonstrate increased levels.

- Drugs that may cause an increase in plasma D-dimer include those administered for antiplatelet therapy.
- Drugs that may cause a decrease in plasma D-dimer include pravastatin and warfarin.
- Placement of tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.
- Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
- Hematocrit greater than 55% may cause falsely prolonged results because of anticoagulant excess relative to plasma volume.
- Incompletely filled collection tubes, specimens contaminated with heparin, clotted specimens, or unprocessed specimens not delivered to the laboratory within 1 to 2 hr of collection should be rejected.
- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.

NURSING IMPLICATIONS AND PROCEDURE**Potential Nursing Problems:**

Problem	Signs & Symptoms	Interventions
Bleeding (<i>Related to altered clotting factors secondary to anticoagulant therapy; depleted clotting factors</i>)	Altered level of consciousness; hypotension; increased heart rate; decreased Hgb and Hct; capillary refill greater than 3 sec; cool extremities	Increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; administer stool softeners as needed; monitor stool for blood; encourage intake of foods rich in vitamin K;

Problem	Signs & Symptoms	Interventions
<p>Protection (<i>Related to increased bleeding risk associated with the hemorrhagic possibility with DIC protection; red cell destruction secondary to altered plasma environment; decreased and defective platelets; blood loss; ineffective clotting</i>)</p>	<p>Pallor; fatigue; weakness; shortness of breath; anxiety; admits easily bruising; increased clotting time</p>	<p>monitor and trend Hgb/Hct; assess skin for petechiae, purpura, hematoma; monitor for blood in emesis, or sputum; institute bleeding precautions (prevent unnecessary venipuncture; avoid IM injections; prevent trauma; be gentle with oral care, suctioning; avoid use of a sharp razor); administer prescribed medications (recombinant human activated protein C; epsilon aminocaproic acid)</p> <p>Assess for symptoms of blood loss (fatigue, pallor, decreased activity); observe for prolonged bleeding associated with ineffective clotting; use pulse oximetry or arterial blood gases (ABGs) to assess oxygenation; administer oxygen as required; administer blood or blood products as required; administer prescribed epoetin alfa; use bleeding precautions (avoid aspirin products, avoid trauma, avoid constipation, avoid forceful nose blowing that could cause nosebleed)</p>
<p>Tissue perfusion (cerebral, peripheral, renal) (<i>Related to altered blood flow associated with platelet clumping</i>)</p>	<p>Hypotension; dizziness; cool extremities; capillary refill greater than 3 sec; weak pedal pulses; altered level of consciousness</p>	<p>Monitor blood pressure; assess for dizziness; check skin temperature for warmth; assess capillary refill; assess pedal pulses; monitor level of consciousness; administer prescribed vasodilators and inotropic drugs; provide oxygen as required</p>

(table continues on page 710)

Problem	Signs & Symptoms	Interventions
Fear (<i>Related to the possibility of death secondary to diagnosis of DIC, MI, PE, DVT or other associated diagnoses</i>)	Verbalization of fear; restlessness; increased tension; continuous questioning; increased blood pressure, heart rate, respiratory rate; diarrhea; anorexia; nausea; pallor; vomiting; fatigue; dry mouth	Evaluate verbal and nonverbal indicators of fear; assess for the cause of fear; acknowledge the patient's awareness of fear; explain all procedures with simple age and culturally appropriate language; administer proscribed mild tranquilizer; maintain a confident, assured professional manner in all patient interactions

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing and evaluating conditions affecting normal blood clot formation.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of hematological diseases and recent surgery.
- ▶ Obtain a history of the patient's cardiovascular, hematopoietic, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Fill tube completely. **Important note:** When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) tubes. Otherwise, when using a standard vacutainer system, the blue top is the first tube collected. When a butterfly is used and due to the added tubing, an extra red-top tube should be collected before the blue-top tube to ensure complete filling of the blue-top tube.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Teach the patient and family about bleeding precautions that can be used to decrease injury risk.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:**Knowledge**

- ▶ Verbalizes understanding that support groups are available to address fears and concerns
- ▶ States understanding of disease process and treatment plan

Skills

- ▶ Participates in discussions related to distinguishing between rational and irrational fears
- ▶ Demonstrates proficiency with the use of positive coping techniques

Attitude

- ▶ Expresses fear related to diagnosis appropriately
- ▶ Complies with the request for psychological evaluation related to fear management

RELATED MONOGRAPHS:

- ▶ Related tests include aPTT, alveolar/arterial gradient, angiography pulmonary, antibodies anticardiolipin, AT-III, blood gases, coagulation factors, CBC platelet count, FDP, fibrinogen, lactic acid, lung perfusion scan, MRI venography, plasminogen, plethysmography, protein S, PT/INR, US venous Doppler extremity studies, and venography lower extremity studies.
- ▶ Refer to the Cardiovascular, Hematopoietic, and Respiratory systems tables at the end of the book for related tests by body system.

Dehydroepiandrosterone Sulfate

SYNONYM/ACRONYM: DHEAS.

COMMON USE: To assist in identifying the cause of infertility, amenorrhea, or hirsutism.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube. Plasma (1 mL) collected in a lavender-top (EDTA) tube is also acceptable. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Immunochemiluminometric assay [ICMA])

Age	Male Conventional Units mcg/dL	Male SI Units micromol/L (Conventional Units × 0.027)	Female Conventional Units mcg/dL	Female SI Units micromol/L (Conventional Units × 0.027)

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

DHEAS is produced by the adrenal cortex and testis; therefore, any condition stimulating these organs or associated feedback mechanisms will result in increased levels.

- Anovulation
- Cushing's syndrome
- Ectopic ACTH-producing tumors
- Hirsutism
- Hyperprolactinemia

- Polycystic ovary (Stein-Leventhal syndrome)
- Virilizing adrenal tumors

Decreased in

DHEAS is produced by the adrenal cortex and testis; therefore, any condition suppressing the normal function of these organs or associated feedback mechanisms will result in decreased levels.

- Addison's disease
- Adrenal insufficiency (primary or secondary)
- Aging adults (*related to natural decline in production with age*)

- Hyperlipidemia
- Pregnancy (*related to DHEAS produced by fetal adrenals and converted to estrogens in the placenta*)
- Psoriasis (*some potent topical medications used for long*

periods of time can result in chronic adrenal insufficiency)

- Psychosis (*related to acute adrenal insufficiency*)

CRITICAL FINDINGS: N/A

D

Drugs of Abuse

Amphetamines	Opiates
Ethanol (Alcohol)	Cocaine
Cannabinoids	Phencyclidine

SYNONYM/ACRONYM: Amphetamines, cannabinoids (THC), cocaine, ethanol (alcohol, ethyl alcohol, ETOH), phencyclidine (PCP), opiates (heroin).

COMMON USE: To assist in rapid identification of commonly abused drugs in suspected drug overdose or for workplace drug screening.

SPECIMEN: For ethanol, serum (1 mL) collected in a red-top tube; plasma (1 mL) collected in a gray-top (sodium fluoride/potassium oxalate) tube is also acceptable. For drug screen, urine (15 mL) collected in a clean plastic container. Gastric contents (20 mL) may also be submitted for testing.

Workplace drug-screening programs, because of the potential medicolegal consequences associated with them, require collection of urine and blood specimens using a *chain of custody protocol*. The protocol provides securing the sample in a sealed transport device in the presence of the donor and a representative of the donor's employer, such that tampering would be obvious. The protocol also provides a written document of specimen transfer from donor to specimen collection personnel, to storage, to analyst, and to disposal.

NORMAL FINDINGS: (Method: Spectrophotometry for ethanol; immunoassay for drugs of abuse)

Ethanol: None detected

Drug screen: None detected

DESCRIPTION: Drug abuse continues to be one of the most significant social and economic problems in the United States. The Substance

Abuse and Mental Health Services Administration (SAMHSA) has identified opiates, cocaine, cannabinoids, amphetamines, and

phencyclidines (PCPs) as the most commonly abused illicit drugs. Alcohol is the most commonly encountered legal substance of abuse. Chronic alcohol abuse can lead to liver disease, high blood pressure, cardiac disease, and birth defects.

This procedure is contraindicated for: N/A

INDICATIONS

- Differentiate alcohol intoxication from diabetic coma, cerebral trauma, or drug overdose
- Investigate suspected drug abuse
- Investigate suspected drug overdose
- Investigate suspected noncompliance with drug or alcohol treatment program
- Monitor ethanol levels when administered to treat methanol intoxication
- Routine workplace screening

	Screening Cutoff Concentrations for Drugs of Abuse Recommended by SAMHSA	Confirmatory Cutoff Concentrations for Drugs of Abuse Recommended by SAMHSA	Detectable Duration After Last Single-Use Dose	Detectable Duration After Last Dose: Prolonged Use
Hallucinogens				
Cannabinoids	50 ng/mL	15 ng/mL	2–7 days	1–2 mo
Phencyclidine	25 ng/mL	25 ng/mL	1 wk	2–4 wk
Opiates				
6-Acetylmorphine	2,000 ng/mL	2,000 ng/mL	1–3 days	1–3 days
Stimulants				
Amphetamines (either amphetamine or methamphetamine) ^a	500 ng/mL	250 ng/mL	48 hr	7–10 days
Cocaine	150 ng/mL	100 ng/mL	3 days	4 days
MDMA (either methylenedioxy-methamphetamine, methylenedioxy-amphetamine, or methylenedioxy-ethylamphetamine)	500 ng/mL	250 ng/mL	24 hr	24 hr

^a To be reported as positive for methamphetamine, the specimen must also contain amphetamine at a concentration of 100 ng/mL or greater.

POTENTIAL DIAGNOSIS

A urine screen merely identifies the presence of these substances in urine; it does not indicate time of

exposure, amount used, quality of the source used, or level of impairment. Positive screens should be considered presumptive. Drug-specific

confirmatory methods should be used to investigate questionable results of a positive urine screen.

CRITICAL FINDINGS

Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

The legal limit for ethanol intoxication varies by state, but in most states, greater than 80 mg/dL (0.08 %) is considered impaired for driving. Levels greater than 300 mg/dL are associated with amnesia, vomiting, double vision, and hypothermia. Levels of 80 to 400 mg/dL are associated with coma and may be fatal. Possible interventions for ethanol toxicity include administration of tap water or 3% sodium bicarbonate lavage, breathing support, and hemodialysis (usually indicated only if levels exceed 300 mg/dL).

Amphetamine intoxication (greater than 200 ng/mL) causes psychoses, tremors, convulsions, insomnia, tachycardia, dysrhythmias, impotence, cerebrovascular accident, and respiratory failure. Possible interventions include emesis (if orally ingested and if the patient has a gag reflex and normal central nervous system [CNS] function), administration of activated charcoal followed by magnesium citrate cathartic, acidification of the urine to promote excretion, and administration of liquids to promote urinary output.

Cocaine intoxication (greater than 1,000 ng/mL) causes short-term symptoms of CNS stimulation, hypertension, tachypnea, mydriasis, and tachycardia. Possible interventions include emesis (if orally ingested and if the patient has a gag reflex and normal CNS function), gastric lavage (if orally ingested), whole-bowel irrigation (if packs of the drug were ingested), airway protection, cardiac support, and administration of diazepam or phenobarbital for convulsions. The use of beta blockers is contraindicated.

Heroin and morphine are opiates that at toxic levels (greater than 200 ng/mL) cause bradycardia, flushing, itching, hypotension, hypothermia, and respiratory depression. Possible interventions include airway protection and the administration of naloxone (Narcan).

PCP intoxication (greater than 100 ng/mL) causes a variety of symptoms depending on the stage of intoxication. Stage I includes psychiatric signs, muscle spasms, fever, tachycardia, flushing, small pupils, salivation, nausea, and vomiting. Stage II includes stupor, convulsions, hallucinations, increased heart rate, and increased blood pressure. Stage III includes further increases of heart rate and blood pressure that may culminate in cardiac and respiratory failure. Possible interventions may include providing

respiratory support, administration of activated charcoal with a cathartic such as sorbitol, gastric lavage and suction, administration of IV nutrition and electrolytes, and acidification of the urine to promote PCP excretion.

INTERFERING FACTORS

- Codeine-containing cough medicines and antidiarrheal preparations, as well as ingestion of large amounts of poppy seeds, may produce a false-positive opiate result.
- Adulterants such as bleach or other strong oxidizers can produce erroneous urine drug screen results.
- Alcohol is a volatile substance, and specimens should be stored in a tightly stoppered containers to avoid falsely decreased values.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with identification of drugs in the body.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's symptoms and previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the entire procedure with the patient, especially if the circumstances require collection of urine and blood specimens using a chain-of-custody protocol. Inform the patient that specimen collection takes approximately 5 to 10 min but may vary depending on the level of patient cooperation.

Address concerns about pain and explain that there may be some discomfort during the venipuncture, but there should be no discomfort during urine specimen collection.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ If appropriate or required: *Make sure a written and informed consent has been signed prior to the procedure.*

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient receiving venipuncture to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection containers with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. For alcohol level, use an approved non-alcohol-containing solution to cleanse the venipuncture site before specimen collection. Perform a venipuncture, as appropriate. For a urine drug screen, instruct the patient to obtain a clean-catch urine specimen.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small

- amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.
- ▶ Follow the chain-of-custody protocol, if required. Monitor specimen collection, labeling, and packaging to prevent tampering. This protocol may vary by institution.
 - ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Ensure that results are communicated to the proper individual, as indicated in the chain-of-custody protocol.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Educate the patient regarding access to counseling services. Provide support and information regarding detoxification programs, as appropriate. Provide contact information, if desired, for the National Institute on Drug Abuse (www.nida.nih.gov).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Refer to the Therapeutic/Toxicology table at the end of the book for related tests.

Ductography

SYNONYM/ACRONYM: Breast ductoscopy, fiberoptic ductoscopy, galactography.

COMMON USE: To visualize and assess the breast ducts for disease and malignancy in women with nipple discharge.

AREA OF APPLICATION: Breast.

CONTRAST: Iodine-based contrast medium.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients younger than age 25 *because the density of the*

breast tissue is such that diagnostic x-rays are of limited value.

-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has

been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of non-ionic contrast or an alternative non-contrast imaging study, if available, may be considered for patients who have severe asthma or who have

experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with bleeding disorders receiving an arterial or venous puncture **because the site may not stop bleeding.**

POTENTIAL DIAGNOSIS

Normal findings in

- Normal breast tissue

Abnormal findings in

- Ductal thickening
- Papillary lesions

CRITICAL FINDINGS

- ◆ Ductal carcinoma in situ (DCIS)
- ◆ Invasive breast cancer

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

D-Xylose Tolerance Test

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in the differential diagnosis of small intestine malabsorption syndromes such as celiac, tropical sprue, and Crohn's diseases.

SPECIMEN: Plasma (1 mL) collected in a gray-top (fluoride/oxalate) tube and urine (10 mL from a 5-hr collection) in a clean amber plastic container.

NORMAL FINDINGS: (Method: Spectrophotometry)

Dose Given	Conventional Units	SI Units (Conventional Units × 0.0666)
	<i>Plasma</i>	
Infant dose 0.5 g/kg (max. 25 g)	Greater than 15 mg/dL after 2 hr	Greater than 1 mmol/L
Pediatric dose 0.5 g/kg (max. 25 g)	Greater than 20 mg/dL after 2 hr	Greater than 1.3 mmol/L
Adult dose 25 g	Greater than 25 mg/dL after 2 hr	Greater than 1.7 mmol/L

Dose Given	Conventional Units	SI Units (Conventional Units \times 0.0666)
5 g (given if patient is known or expected to have severe symptoms)	Greater than 20 mg/dL after 2 hr	Greater than 1.3 mmol/L

Children

Adults

Older adults (age 65 years and older)

Urine

Greater than 16%–40% of dose in 5 hr urine sample

Greater than 16% or greater than 4 g of dose in 5 hr urine sample

Greater than 14% or greater than 3.5 g of dose in 5 hr urine sample

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in: N/A

Decreased in

Conditions that involve defective mucosal absorption of carbohydrates and other nutrients.

- Amyloidosis
- Bacterial overgrowth (***sugar is consumed by bacteria***)
- Eosinophilic gastroenteritis

- Lymphoma
- Nontropical sprue (celiac disease, gluten-induced enteropathy)
- Parasitic infestations (*Giardia*, schistosomiasis, hookworm)
- Postoperative period after massive resection of the intestine
- Radiation enteritis
- Scleroderma
- Small bowel ischemia
- Tropical sprue
- Whipple's disease
- Zollinger-Ellison syndrome

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Echocardiography

SYNONYM/ACRONYM: Doppler echo, Doppler ultrasound of the heart, echo.

COMMON USE: To assist in diagnosing cardiovascular disorders such as defect, heart failure, tumor, infection, and bleeding.

AREA OF APPLICATION: Chest/thorax.

CONTRAST: Can be done with or without noniodinated contrast medium (lipid microspheres).

DESCRIPTION: Echocardiography, a noninvasive ultrasound (US) procedure, uses high-frequency sound waves of various intensities to assist in diagnosing cardiovascular disorders. The procedure records the echoes created by the deflection of an ultrasonic beam off the cardiac structures and allows visualization of the size, shape, position, thickness, and movement of all four valves, atria, ventricular and atria septa, papillary muscles, chordae tendineae, and ventricles. This study can also determine blood-flow velocity and direction and the presence of pericardial effusion during the movement of the transducer over areas of the chest.

Electrocardiography and phonocardiography can be done simultaneously to correlate the findings with the cardiac cycle. These procedures can be done at the bedside or in a specialized department, health-care provider's (HPC's) office, or clinic.

Included in the study are the M-mode method, which produces a linear tracing of timed motions of the heart, its structures, and associated measurements over time; and the two-dimensional method, using real-time Doppler color-flow imaging with pulsed and continuous-wave Doppler spectral tracings, which produces

a cross-section of the structures of the heart and their relationship to one another, including changes in the coronary vasculature, velocity and direction of blood flow, and areas of eccentric blood flow. Doppler color-flow imaging may also be helpful in depicting the function of biological and prosthetic valves.

Echocardiography has become the method of choice for cardiac stress testing and evaluation of chest pain. Congenital heart disease such as atrial or ventricular septal defects are frequently evaluated with echocardiography. Cardiac contrast medium such as DEFINITY or Optison may be used to improve the visualization of the heart.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect atrial tumors (myxomas)
- Detect subaortic stenosis as evidenced either by displacement of the anterior atrial leaflet or by a reduction in aortic valve flow, depending on the obstruction
- Detect ventricular or atrial mural thrombi and evaluate cardiac wall motion after myocardial infarction
- Determine the presence of pericardial effusion, tamponade, and pericarditis

- Determine the severity of valvular abnormalities such as stenosis, prolapse, and regurgitation
- Evaluate congenital heart disorders
- Evaluate endocarditis
- Evaluate or monitor prosthetic valve function
- Evaluate the presence of shunt flow and continuity of the aorta and pulmonary artery
- Evaluate unexplained chest pain, electrocardiographic changes, and abnormal chest x-ray (e.g., enlarged cardiac silhouette)
- Evaluate ventricular aneurysms and/or thrombus
- Measure the size of the heart's chambers and determine if hypertrophic cardiomyopathy or congestive heart failure is present

POTENTIAL DIAGNOSIS

Normal findings in

- Normal appearance in the size, position, structure, and movements of the heart valves visualized and recorded in a combination of ultrasound modes; and normal heart muscle walls of both ventricles and left atrium, with adequate blood filling. Established values for the measurement of heart activities obtained by the study may vary by HCP and institution.

Abnormal findings in

- Aortic aneurysm
- Aortic valve abnormalities
- Cardiac neoplasm
- Cardiomyopathy
- Congenital heart defect
- Congestive heart failure
- Coronary artery disease (CAD)
- Endocarditis
- Mitral valve abnormalities
- Myxoma
- Pericardial effusion, tamponade, and pericarditis
- Pulmonary hypertension
- Pulmonary valve abnormalities
- Septal defects

- Ventricular hypertrophy
- Ventricular or atrial mural thrombi

CRITICAL FINDINGS

- Aortic aneurysm
- Infection
- Obstruction
- Tumor with significant mass effect (rare)

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Incorrect placement of the transducer over the desired test site.
- Retained barium from a previous radiological procedure.
- Patients who are dehydrated, resulting in failure to demonstrate the boundaries between organs and tissue structures.

- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- The presence of chronic obstructive pulmonary disease or use of mechanical ventilation, which increases the air between the heart and chest wall (hyperinflation) and can attenuate the ultrasound waves.
- Obese patients due to the enlarged space between the transducer and the heart.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- The presence of arrhythmias.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing cardiac (heart) function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). Ensure that barium studies were performed at least 24 hr before this test.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that there should be no discomfort during the procedure. Inform the patient the procedure is performed in a US or cardiology department, usually by an HCP, and takes approximately 30 to 60 min.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, contrast medium, or emergency medications.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry, and other metallic objects from the area to be examined.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, contrast medium, or emergency medications.

- ▶ Expose the chest, and attach electrocardiogram leads for simultaneous tracings, if desired.
- ▶ Apply conductive gel to the chest. Place the transducer on the chest surface along the left sternal border, the subxiphoid area, suprasternal notch, and supraclavicular areas to obtain views and tracings of the portions of the heart. Scan the areas by systematically moving the probe in a perpendicular position to direct the ultrasound waves to each part of the heart.
- ▶ To obtain different views or information about heart function, position the patient on the left side and/or sitting up, or request that the patient breathe slowly or hold the breath during the procedure. To evaluate heart function changes, the patient may be asked to inhale amyl nitrate (vasodilator).
- ▶ Administer contrast medium, if ordered. A second series of images is obtained.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the study is completed, remove the gel from the skin.
- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are

overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a "Mediterranean"-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and non-tropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approach to Stop Hypertension (DASH) makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

- Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information

regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, blood gases, blood pool imaging, calcium, chest x-ray, cholesterol (total, HDL, LDL), CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, echocardiography, echocardiography transesophageal, electrocardiogram, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isos, lipoprotein electrophoresis, lung perfusion scan, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, pulse oximetry, sodium, triglycerides, and troponin.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Echocardiography, Transesophageal

SYNONYM/ACRONYM: Echo, TEE.

COMMON USE: To assess and visualize cardiovascular structures toward diagnosing disorders such as tumors, congenital defects, valve disorders, chamber disorders, and bleeding.

AREA OF APPLICATION: Chest/thorax.

CONTRAST: Can be done with or without noniodinated contrast medium (lipid microspheres).

DESCRIPTION: Transesophageal echocardiography (TEE) is performed to assist in the diagnosis of cardiovascular disorders when noninvasive echocardiography is contraindicated or does not reveal enough information to confirm a diagnosis. Noninvasive echocardiography may be an inadequate procedure for patients who are

obese, have chest wall structure abnormalities, or have chronic obstructive pulmonary disease (COPD). TEE provides a better view of the posterior aspect of the heart, including the atrium and aorta. It is done with a transducer attached to a gastro-scope that is inserted into the esophagus. The transducer and

the ultrasound (US) instrument allow the beam to be directed to the back of the heart. The echoes are amplified and recorded on a screen for visualization and recorded on graph paper or videotape. The depth of the endoscope and movement of the transducer is controlled to obtain various images of the heart structures. TEE is usually performed during surgery; it is also used on patients who are in the intensive care unit, in whom the transmission of waves to and from the chest has been compromised and more definitive information is needed. The images obtained by TEE have better resolution than those obtained by routine transthoracic echocardiography because TEE uses higher frequency sound waves and offers closer proximity of the transducer to the cardiac structures. Cardiac contrast medium such as DEFINITY or Optison, is used to improve the visualization of viable myocardial tissue within the heart.

This procedure is contraindicated for: N/A

 A variety of circumstances that may be considered absolute or relative depending on the facility's providers:

- Barrett esophagus
- Bleeding disorders
- Esophageal obstruction (e.g., spasm, stricture, tumor)
- Esophageal trauma (e.g., laceration, perforation)
- Esophageal varices
- Known upper esophagus disease
- Tracheoesophageal fistula
- Recent esophageal surgery (e.g., esophagectomy or esophagogastrectomy)
- Unstable cardiac or respiratory status
- Zenker diverticulum

INDICATIONS

- Confirm diagnosis if conventional echocardiography does not correlate with other findings
- Detect and evaluate congenital heart disorders
- Detect atrial tumors (myxomas)
- Detect or determine the severity of valvular abnormalities and regurgitation
- Detect subaortic stenosis as evidenced by displacement of the anterior atrial leaflet and reduction in aortic valve flow, depending on the obstruction
- Detect thoracic aortic dissection and coronary artery disease (CAD)
- Detect ventricular or atrial mural thrombi and evaluate cardiac wall motion after myocardial infarction
- Determine the presence of pericardial effusion
- Evaluate aneurysms and ventricular thrombus
- Evaluate or monitor biological and prosthetic valve function
- Evaluate septal defects
- Measure the size of the heart's chambers and determine if hypertrophic cardiomyopathy or congestive heart failure is present
- Monitor cardiac function during open heart surgery (most sensitive method for monitoring ischemia)
- Reevaluate after inadequate visualization with conventional echocardiography as a result of obesity, trauma to or deformity of the chest wall, or lung hyperinflation associated with COPD

POTENTIAL DIAGNOSIS

Normal findings in

- Normal appearance of the size, position, structure, movements of the heart valves and heart muscle

walls, and chamber blood filling; no evidence of valvular stenosis or insufficiency, cardiac tumor, foreign bodies, or CAD. The established values for the measurement of heart activities obtained by the study may vary by health-care provider (HCP) and institution.

Abnormal findings in

- Aortic aneurysm
- Aortic valve abnormalities
- CAD
- Cardiomyopathy
- Congenital heart defects
- Congestive heart failure
- Mitral valve abnormalities
- Myocardial infarction
- Myxoma
- Pericardial effusion
- Pulmonary hypertension
- Pulmonary valve abnormalities
- Septal defects
- Shunting of blood flow
- Thrombus
- Ventricular hypertrophy
- Ventricular or atrial mural thrombi

CRITICAL FINDINGS

- Aortic aneurysm
- Aortic dissection

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value,

name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Incorrect placement of the transducer over the desired test site.
- Retained barium from a previous radiological procedure.
- Patients who are dehydrated, resulting in failure to demonstrate the boundaries between organs and tissue structures.
- Large diaphragmatic hernia.
- Unknown upper esophageal pathology.
- Conditions such as esophageal dysphagia and irradiation of the mediastinum **related to difficulty manipulating the US probe once it has been inserted in the esophagus.**
- The presence of COPD or use of mechanical ventilation, which increases the air between the heart and chest wall (hyperinflation) and can attenuate the US waves.
- Obese patients due to the enlarged space between the transducer and the heart.
- The presence of arrhythmias.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing cardiac (heart) function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy). Ensure that barium studies were performed at least 24 hr before this test.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure. Explain that some pain may be experienced during the test, and there may be moments of discomfort during insertion of the scope. Lidocaine is sprayed in the patient's throat to reduce discomfort caused by the presence of the endoscope. Inform the patient that the procedure is performed in a US or cardiology department, usually by an HCP, and takes approximately 30 to 60 min.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is

important in providing psychological support before, during, and after the procedure.

- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

While complications are rare, trauma to the upper GI tract (e.g., esophageal bleeding, perforation, or rupture) may occur. Other potential complications include undiagnosed esophageal pathology, laryngospasm, or bronchospasm.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary and fluid restriction for at least 8 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Obtain and record the patient's vital signs.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Ask the patient, as appropriate, to remove his or her dentures.
- ▶ Monitor pulse oximetry to determine oxygen saturation in sedated patients.

- ▶ Establish an IV fluid line for the injection of saline, sedatives, contrast medium, or emergency medications.
- ▶ Expose the chest, and attach electrocardiogram leads for simultaneous tracings, if desired.
- ▶ Spray or swab the patient's throat with a local anesthetic, and place the oral bridge device in the mouth to prevent biting of the endoscope.
- ▶ Place the patient in a left side-lying position on a flat table with foam wedges to help maintain position and immobilization. The pharyngeal area is anesthetized, and the endoscope with the ultrasound device attached to its tip is inserted 30 to 50 cm to the posterior area of the heart, as in any esophagogastroduodenoscopy procedure.
- ▶ Ask the patient to swallow as the scope is inserted. When the transducer is in place, the scope is manipulated by controls on the handle to obtain scanning that provides real-time images of the heart motion and recordings of the images for viewing. Actual scanning is usually limited to 15 min or until the desired number of image planes is obtained at different depths of the scope.
- ▶ Administer contrast medium, if ordered. A second series of images is obtained.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
 - ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
 - ▶ Instruct the patient to resume usual diet and activity 4 to 6 hr after the test, as directed by the HCP.
 - ▶ Instruct the patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.
- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
 - ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a "Mediterranean"-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approach to Stop Hypertension (DASH) makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

Social and Cultural Considerations:

- Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
 - ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, blood gases, blood pool imaging, calcium, chest x-ray, cholesterol (total, HDL, LDL), CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, echocardiography, electrocardiogram, exercise stress test, glucose, glycosylated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isos, lipoprotein electrophoresis, lung perfusion scan, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, pulse oximetry, sodium, triglycerides, and troponin.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Electrocardiogram

SYNONYM/ACRONYM: ECG, EKG.**COMMON USE:** To evaluate the electrical impulses generated by the heart during the cardiac cycle to assist with diagnosis of cardiac arrhythmias, blocks, damage, infection, or enlargement.**AREA OF APPLICATION:** Heart.**CONTRAST:** None.

DESCRIPTION: The cardiac muscle consists of three layers of cells: the inner layer called the *endocardium*, the middle layer called the *myocardium*, and the outer

layer called the *epicardium*. The systolic phase of the cardiac cycle reflects the contraction of the myocardium, whereas the diastolic phase takes place when the

heart relaxes to allow blood to rush in. All muscle cells have a characteristic rate of contraction called *depolarization*. Therefore, the heart will maintain a predetermined heart rate unless other stimuli are received.

The monitoring of pulse and blood pressure evaluates only the mechanical activity of the heart. The electrocardiogram (ECG), a noninvasive study, measures the electrical currents or impulses that the heart generates during a cardiac cycle (see figure of a normal ECG at end of monograph). Electrical impulses travel through a conduction system beginning with the sinoatrial (SA) node and moving to the atrioventricular (AV) node via internodal pathways. From the AV node, the impulses travel to the bundle of His and onward to the right and left bundle branches. These bundles are located within the right and left ventricles. The impulses continue to the cardiac muscle cells by terminal fibers called *Purkinje fibers*. The ECG is a graphic display of the electrical activity of the heart, which is analyzed by time intervals and segments. Continuous tracing of the cardiac cycle activity is captured as heart cells are electrically stimulated, causing depolarization and movement of the activity through the cells of the myocardium.

The ECG study is completed by using 12, 15, or 18 electrodes attached to the skin surface to obtain the total electrical activity of the heart. Each lead records the electrical potential between the limbs or between the heart and limbs. The ECG machine records and marks the 12 leads (most common system used) on the strip of paper in the machine

in proper sequence, usually 6 in. of the strip for each lead. The ECG pattern, called a *heart rhythm*, is recorded by a machine as a series of waves, intervals, and segments, each of which pertains to a specific occurrence during the contraction of the heart. The ECG tracings are recorded on graph paper using vertical and horizontal lines for analysis and calculations of time, measured by the vertical lines (1 mm apart and 0.04 sec per line), and of voltage, measured by the horizontal lines (1 mm apart and 0.5 mV per 5 squares). A pulse rate can be calculated from the ECG strip to obtain the beats per minute. The P wave represents the depolarization of the atrial myocardium; the QRS complex represents the depolarization of the ventricular myocardium; the P-R interval represents the time from beginning of the excitation of the atrium to the beginning of the ventricular excitation; and the ST segment has no deflection from baseline, but in an abnormal state may be elevated or depressed. An abnormal rhythm is called an *arrhythmia*.

The ankle-brachial index (ABI) can also be assessed during this study. This noninvasive, simple comparison of blood pressure measurements in the arms and legs can be used to detect peripheral artery disease (PAD). A Doppler stethoscope is used to obtain the systolic pressure in either the dorsalis pedis or the posterior tibial artery. This ankle pressure is then divided by the highest brachial systolic pressure acquired after taking the blood pressure in both arms of the patient. This index should be

greater than 1. When the index falls below 0.5, blood flow impairment is considered significant. Patients should be scheduled for a vascular consult for an abnormal ABI. Patients with diabetes or kidney disease, as well as some elderly patients, may have a falsely elevated ABI due to calcifications of the vessels in the ankle causing an increased systolic pressure. The ABI test approaches 95% accuracy in detecting PAD. However, a normal ABI value does not absolutely rule out the possibility of PAD for some individuals, and additional tests should be done to evaluate symptoms.

This procedure is contraindicated for: N/A

INDICATIONS

- Assess the extent of congenital heart disease
- Assess the extent of myocardial infarction (MI) or ischemia, as indicated by abnormal ST segment, interval times, and amplitudes
- Assess the function of heart valves
- Assess global cardiac function
- Detect arrhythmias, as evidenced by abnormal wave deflections
- Detect peripheral artery disease (PAD)
- Detect pericarditis, shown by ST segment changes or shortened P-R interval
- Determine electrolyte imbalances, as evidenced by short or prolonged Q-T interval
- Determine hypertrophy of the chamber of the heart or heart hypertrophy, as evidenced by P or R wave deflections
- Evaluate and monitor cardiac pacemaker function
- Evaluate and monitor the effect of drugs, such as digitalis, antiarrhythmics, or vasodilating agents

- Monitor ECG changes during an exercise test
- Monitor rhythm changes during the recovery phase after an MI

POTENTIAL DIAGNOSIS

Normal findings in

- Normal heart rate according to age: range of 60 to 100 beats/min in adults
- Normal, regular rhythm and wave deflections with normal measurement of ranges of cycle components and height, depth, and duration of complexes as follows:
 - P wave: 0.12 sec or three small blocks with amplitude of 2.5 mm
 - Q wave: less than 0.04 mm
 - R wave: 5 to 27 mm amplitude, depending on lead
 - T wave: 1 to 13 mm amplitude, depending on lead
 - QRS complex: 0.1 sec or two and a half small blocks
 - ST segment: 1 mm

Abnormal findings in

- Arrhythmias
- Atrial or ventricular hypertrophy
- Bundle branch block
- Electrolyte imbalances
- Heart rate of 40 to 60 beats/min in adults
- MI or ischemia
- PAD
- Pericarditis
- Pulmonary infarction
- P wave: An enlarged P wave deflection could indicate atrial enlargement; an absent or altered P wave could suggest that the electrical impulse did not come from the SA node
- P-R interval: An increased interval could imply a conduction delay in the AV node
- QRS complex: An enlarged Q wave may indicate an old infarction; an enlarged deflection could indicate ventricular hypertrophy; increased time duration may indicate a bundle branch block

- **ST segment:** A depressed ST segment indicates myocardial ischemia; an elevated ST segment may indicate an acute MI or pericarditis; a prolonged ST segment (or prolonged QT) may indicate hypocalcemia. A shortened ST segment may indicate hypokalemia
- **Tachycardia** greater than 120 beats/min
- **T wave:** A flat or inverted T wave may indicate myocardial ischemia, infarction, or hypokalemia; a tall, peaked T wave with a shortened QT interval may indicate hyperkalemia

CRITICAL FINDINGS

Adult

- Acute changes in ST elevation are usually associated with acute MI or pericarditis.
- Asystole
- Heart block, second- and third-degree with bradycardia less than 60 beats/min
- Pulseless electrical activity
- Pulseless ventricular tachycardia
- Premature ventricular contractions (PVCs) greater than three in a row, pauses greater than 3 sec, or identified blocks
- Unstable tachycardia
- Ventricular fibrillation

Pediatric

- Asystole
- Bradycardia less than 60 beats/min
- Pulseless electrical activity
- Pulseless ventricular tachycardia
- Supraventricular tachycardia
- Ventricular fibrillation

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional

nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair the results of the examination

- Anatomic variation of the heart (i.e., the heart may be rotated in both the horizontal and frontal planes).
- Distortion of cardiac cycles due to age, gender, weight, or a medical condition (e.g., infants, women [may exhibit slight ST segment depression], obese patients, pregnant patients, patients with ascites).
- High intake of carbohydrates or electrolyte imbalances of potassium or calcium.
- Improper placement of electrodes or inadequate contact between skin and electrodes because of insufficient conductive gel or poor placement, which can cause ECG tracing problems.
- ECG machine malfunction or interference from electromagnetic waves in the vicinity.
- Inability of the patient to remain still during the procedure, because movement, muscle tremor, or twitching can affect accurate test recording.

- Increased patient anxiety, causing hyperventilation or deep respirations.
- Medications such as barbiturates and digitalis.
- Strenuous exercise before the procedure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing cardiac (heart) function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives. Ask if the patient has had a heart transplant, implanted pacemaker, or internal cardiac defibrillator.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain related to the procedure and explain that there should be no discomfort related to the procedure. Inform the patient that the procedure is performed by an HCP and takes approximately 15 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with pretesting preparations.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline values.
- ▶ Place patient in a supine position. Expose and appropriately drape the chest, arms, and legs.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Prepare the skin surface with alcohol and remove excess hair. Use clippers to remove hair from the site, if appropriate. Dry skin sites.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Apply the electrodes in the proper position. When placing the six unipolar chest leads, place V_1 at the fourth intercostal space at the border of the right sternum, V_2 at the fourth intercostal space at the border of the left sternum, V_3 between V_2 and V_4 , V_4 at the fifth intercostal space at the midclavicular line, V_5 at the left anterior axillary line at the level of V_4 horizontally, and V_6 at the level of V_4 horizontally and at the left midaxillary line. The wires are connected to the matched electrodes and the ECG machine. Chest leads (V_1 , V_2 , V_3 , V_4 , V_5 , and V_6) record data from the horizontal plane of the heart.
- ▶ Place three limb bipolar leads (two electrodes combined for each) on the

arms and legs. Lead I is the combination of two arm electrodes, lead II is the combination of right arm and left leg electrodes, and lead III is the combination of left arm and left leg electrodes. Limb leads (I, II, III, aVL, aVF, and aVR) record data from the frontal plane of the heart.

- ▶ The machine is set and turned on after the electrodes, grounding, connections, paper supply, computer, and data storage device are checked.
- ▶ If the patient has any chest discomfort or pain during the procedure, mark the ECG strip indicating that occurrence.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the procedure is complete, remove the electrodes and clean the skin where the electrode was applied.
- ▶ Evaluate the results in relation to previously performed ECGs. Denote cardiac rhythm abnormalities on the strip.
- ▶ Monitor vital signs and compare with baseline values. Protocols may vary among facilities.
- ▶ Instruct the patient to immediately notify an HCP of chest pain, changes in pulse rate, or shortness of breath.
- ▶ Recognize anxiety related to the test results and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing coronary artery disease (CAD) or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated

LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation of moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a "Mediterranean"-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approach to Stop Hypertension (DASH) makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

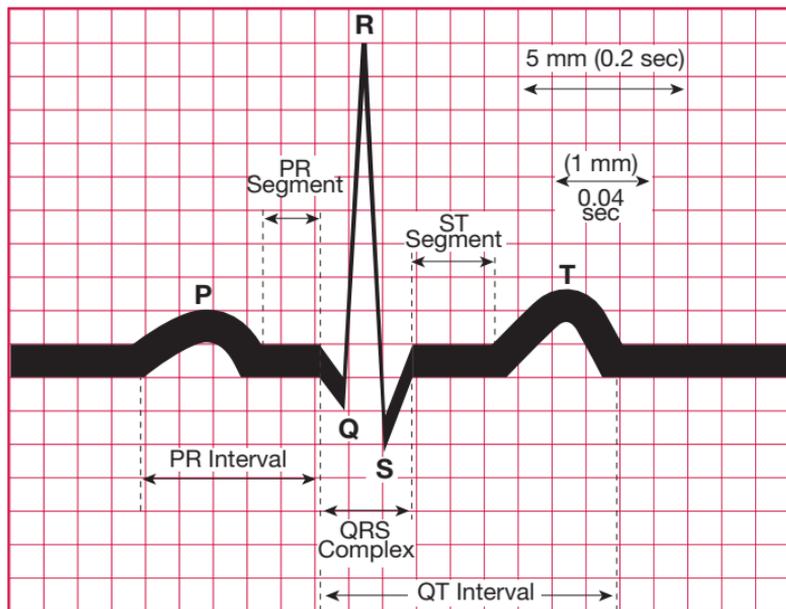

- ▶ **Social and Cultural Considerations:** Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.

- Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org), the NHLBI (www.nhlbi.nih.gov), or the Legs for Life (www.legsforlife.org).
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change

in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, blood gases, blood pool imaging, calcium, chest x-ray, cholesterol (total, HDL, LDL), CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, echocardiography, echocardiography transesophageal, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isos, lipoprotein electrophoresis, lung perfusion scan, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, pulse oximetry, sodium, triglycerides, and troponin.
- Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Electroencephalography

SYNONYM/ACRONYM: Electrical activity (for sleep disturbances), EEG.

COMMON USE: To assess the electrical activity in the brain toward assisting in diagnosis of brain death, injury, infection, and bleeding.

AREA OF APPLICATION: Brain.

CONTRAST: None.

DESCRIPTION: Electroencephalography (EEG) is a noninvasive study that measures the brain's electrical activity and records that activity on graph paper. These electrical impulses arise from the brain cells of the cerebral cortex. Electrodes, placed at 8 to 20 sites (or pairs of sites) on the patient's scalp, transmit the different frequencies and amplitudes of the brain's electrical activity to the EEG machine, which records the results in graph form on a moving paper strip. This procedure can evaluate responses to various stimuli, such as flickering light, hyperventilation, auditory signals, or somatosensory signals generated by skin electrodes. The procedure is usually performed in a room designed to eliminate electrical interference and minimize distractions. An EEG can be done at the bedside, and a health-care provider (HCP) analyzes the waveforms. The test is used to detect epilepsy, intracranial abscesses, or tumors; to evaluate cerebral involvement due to head injury or meningitis; and to monitor for cerebral tissue ischemia during surgery when cerebral vessels must be occluded. EEG is also used to confirm brain death, which can be defined as absence of electrical activity in

the brain. To evaluate abnormal EEG waves further, the patient may be connected to an ambulatory EEG system similar to a Holter monitor for the heart. Patients keep a journal of their activities and any symptoms that occur during the monitoring period.

This procedure is contraindicated for: N/A

INDICATIONS

- Confirm brain death
- Confirm suspicion of increased intracranial pressure caused by trauma or disease
- Detect cerebral ischemia during endarterectomy
- Detect intracranial cerebrovascular lesions, such as hemorrhages and infarcts
- Detect seizure disorders and identify focus of seizure and seizure activity, as evidenced by abnormal spikes and waves recorded on the graph
- Determine the presence of tumors, abscesses, or infection
- Evaluate the effect of drug intoxication on the brain
- Evaluate sleeping disorders, such as sleep apnea and narcolepsy
- Identify area of abnormality in dementia

POTENTIAL DIAGNOSIS

Normal findings in

- Normal occurrences of alpha, beta, theta, and delta waves (rhythms varying depending on the patient's age)
- Normal frequency, amplitude, and characteristics of brain waves

Abnormal findings in

- Abscess
- Brain death
- Cerebral infarct
- Encephalitis
- Glioblastoma and other brain tumors
- Head injury
- Hypocalcemia or hypoglycemia
- Intracranial hemorrhage
- Meningitis
- Migraine headaches
- Narcolepsy
- Seizure disorders (grand mal, focal, temporal lobe, myoclonic, petit mal)
- Sleep apnea

CRITICAL FINDINGS

- Abscess
- Brain death
- Head injury
- Hemorrhage
- Intracranial hemorrhage

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value,

name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Drugs and substances such as sedatives, anticonvulsants, anxiolytics, alcohol, and stimulants such as caffeine and nicotine.
- Hypoglycemic or hypothermic states.
- Hair that is dirty, oily, or sprayed or treated with hair preparations.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient/family this procedure can assist in measuring the electrical activity in the brain.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional

supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and assure the patient there is no discomfort during the procedure, but if needle electrodes are used, a slight pinch may be felt. Explain that electricity flows from the patient's body, not into the body, during the procedure. Explain that the procedure reveals brain activity only, not thoughts, feelings, or intelligence. Inform the patient the procedure is performed in a neurodiagnostic department, usually by an HCP and support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that he or she may be asked to alter breathing pattern; be asked to follow simple commands such as opening or closing eyes, blinking, or swallowing; be stimulated with bright light; or be given a drug to induce sleep during the study.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to clean the hair and to refrain from using hair sprays, creams, or solutions before the test.
- ▶ Instruct the patient to limit sleep to 5 hr for an adult and 7 hr for a child the night before the study. Young infants and children should not be allowed to nap before the study.
- ▶ Instruct the patient to eat a meal before the study and to avoid stimulants such as caffeine and nicotine for 8 hr prior to the procedure. Under medical direction, the patient should avoid sedatives, anticonvulsants, anxiolytics, and alcohol for 24 to 48 hr before the test.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with pretesting preparations. Ensure that caffeine-containing beverages were withheld for 8 hr before the procedure and that a meal was ingested before the study.
- ▶ Ensure that all substances with the potential to interfere with test results were withheld for 24 to 48 hr before the test.
- ▶ Ensure that the patient is able to relax; report any extreme anxiety or restlessness.
- ▶ Ensure that hair is clean and free of hair sprays, creams, or solutions.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Place the patient in the supine position in a bed or in a semi-Fowler's position on a recliner in a special room protected from any noise or electrical interferences that could affect the tracings.
- ▶ Remind the patient to relax and not to move any muscles or parts of the face or head. The HCP should be able to observe the patient for movements or other interferences through a window into the test room.
- ▶ The electrodes are prepared and applied to the scalp. Electrodes are placed in as many as 20 locations over the frontal, temporal, parietal, and occipital areas, and amplifier wires are attached. An electrode is also attached to each earlobe as grounding electrodes. At this time, a baseline recording can be made with the patient at rest.
- ▶ Recordings are made with the patient at rest and with eyes closed. Recordings are stopped about every 5 min to allow the patient to move. Recordings are also made during a drowsy and sleep period, depending on the patient's clinical condition and symptoms.
- ▶ Procedures (e.g., stroboscopic light stimulation, hyperventilation to induce alkalosis, and sleep induction by administration of sedative to detect abnormalities that occur only during sleep) may be done to bring out abnormal electrical activity or other brain abnormalities.

Observations for seizure activity are carried out during the study, and a description and time of activity is noted by the HCP.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ When the procedure is complete, remove electrodes from the hair and remove paste by cleansing with oil or witch hazel.
- ▶ Allow the patient to recover if a sedative was given during the test. Bedside rails are put in the raised position for safety.
- ▶ Instruct the patient to resume medications, as directed by the HCP.
- ▶ Instruct the patient to report any seizure activity.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test

results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CSF analysis, CT brain, evoked brain potentials (SER, VER), MRI brain, and PET brain.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Electromyography

SYNONYM/ACRONYM: Electrodiagnostic study, EMG, neuromuscular junction testing.

COMMON USE: To assess the electrical activity within the skeletal muscles to assist in diagnosing diseases such as muscular dystrophy, Guillain-Barré, polio, and other myopathies.

AREA OF APPLICATION: Muscles.

CONTRAST: None.

DESCRIPTION: Electromyography (EMG) measures skeletal muscle activity during rest, voluntary contraction, and electrical stimulation. Percutaneous extracellular needle electrodes containing fine wires are inserted into selected muscle groups to detect neuromuscular

abnormalities and measure nerve and electrical conduction properties of skeletal muscles. The electrical potentials are amplified, displayed on a screen in wave-forms, and electronically recorded, similar to electrocardiography. Comparison and analysis of the

E amplitude, duration, number, and configuration of the muscle activity provide diagnostic information about the extent of nerve and muscle involvement in the detection of primary muscle diseases, including lower motor neuron, anterior horn cell, or neuromuscular junction diseases; defective transmission at the neuromuscular junction; and peripheral nerve damage or disease. The responses of a relaxed muscle are electrically silent, but spontaneous muscle movement such as fibrillation and fasciculation can be detected in a relaxed, denervated muscle. Muscle action potentials are detected with minimal or maximal muscle contractions and the differences in the size and numbers of activity potentials during voluntary contractions determine whether the muscle weakness is a disease of the striated muscle fibers or cell membranes (myogenic) or a disease of the lower motor neuron (neurogenic). Nerve conduction studies (electroneurography) are commonly done in conjunction with electromyography; the combination of the procedures is known as electromyoneurography. The major use of the examination lies in differentiating among the following disease classes: primary myopathy, peripheral motor neuron disease, and disease of the neuromuscular junction.

EMG can aid with the diagnosis of nerve compression or injury such as carpal tunnel syndrome, nerve root injury such as sciatica, or other problems on the muscles or nerves. An EMG uses tiny devices called electrodes which are inserted directly into a muscle to transmit or detect electrical signals. A nerve conduction study or

nerve conduction velocity test (NCV) which is another part of an EMG uses electrodes taped to the skin to measure the strength and speed of the signals traveling between two or more points.

This procedure is contraindicated for

- ◆ Patients with extensive skin infection or with an infection at the sites of electrode placement **to avoid risk of spreading infection into the muscle**, or who are receiving anticoagulant therapy **to avoid bleeding**.

INDICATIONS

- Assess primary muscle diseases affecting striated muscle fibers or cell membrane, such as muscular dystrophy or myasthenia gravis
- Detect muscle disorders caused by diseases of the lower motor neuron involving the motor neuron on the anterior horn of the spinal cord, such as anterior poliomyelitis, amyotrophic lateral sclerosis, amyotonia, and spinal tumors
- Detect muscle disorders caused by diseases of the lower motor neuron involving the nerve root, such as Guillain-Barré syndrome, herniated disk, or spinal stenosis
- Detect neuromuscular disorders, such as peripheral neuropathy caused by diabetes or alcoholism, and locate the site of the abnormality
- Determine if a muscle abnormality is caused by the toxic effects of drugs (e.g., antibiotics, chemotherapy) or toxins (e.g., *Clostridium botulinum*, snake venom, heavy metals)
- Differentiate between primary and secondary muscle disorders or between neuropathy and myopathy
- Differentiate secondary muscle disorders caused by polymyositis, sarcoidosis, hypocalcemia, thyroid toxicity, tetanus, and other disorders

- Monitor and evaluate progression of myopathies or neuropathies, including confirmation of diagnosis of carpal tunnel syndrome

POTENTIAL DIAGNOSIS

Normal findings in

- Normal muscle electrical activity during rest and contraction states

Abnormal findings in

- Evidence of neuromuscular disorders or primary muscle disease (*Note:* Findings must be correlated with the patient's history, clinical features, and results of other neurodiagnostic tests.):

Amiotrophic lateral sclerosis

Bell's palsy

Beriberi

Carpal tunnel syndrome

Dermatomyositis

Diabetic peripheral neuropathy

Eaton-Lambert syndrome

Guillain-Barré syndrome

Multiple sclerosis

Muscular dystrophy

Myasthenia gravis

Myopathy

Polymyositis as indicated by fast, small spontaneous waveforms

Radiculopathy

Traumatic injury

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Age-related decreases in electrical activity.
- Medications such as muscle relaxants, cholinergics, and anticholinergics.
- Improper placement of surface or needle electrodes.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in measuring the electrical activity of the muscles.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and warn the patient the procedure may be uncomfortable, but an analgesic or sedative will be administered. Inform the patient that as many as 10 electrodes may be inserted at various locations on the body. Inform the patient the procedure is performed in a special laboratory by a health-care provider (HCP) and takes approximately 1 to 3 hr to complete, depending on the patient's condition.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Assess for the ability to comply with directions given for exercising during the test.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Under medical direction, the patient should avoid muscle relaxants, cholinergics, and anticholinergics for 3 to 6 days before the test.
- ▶ Instruct the patient to refrain from smoking and drinking caffeine-containing beverages for 3 hr before the procedure. Protocols may vary among facilities.

▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

EMG is a low-risk procedure, and complications are rare. There is a small risk of bleeding and infection or nerve injury where the needle electrodes are inserted.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has refrained from smoking and drinking caffeine-containing beverages for 3 hr before the procedure.
- ▶ Ensure medications such as muscle relaxants, cholinergics, and anticholinergics have been withheld, as ordered.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Place the patient in a supine or sitting position depending on the location of the muscle to be tested. Ensure that the area or room is protected from noise or metallic interference that may affect the test results.
- ▶ Ask the patient to remain very still and relaxed and to cooperate with instructions given to contract muscles during the procedure.
- ▶ Administer mild analgesic (adult) or sedative (children), as ordered, to promote a restful state before the procedure.
- ▶ Cleanse the skin thoroughly with alcohol pads, as necessary.
- ▶ Observe that a small needle is inserted into the muscle being examined and acts as a recording electrode. A second electrode, a reference electrode, is placed on the skin surface near the recording electrode. An oscilloscope

displays any spontaneous electrical activity while the patient keeps the muscle at rest. The electrical waves produced will be examined for the number, amplitude, and form.

- ▶ Ask the patient to alternate between a relaxed and a contracted muscle state or to perform progressive muscle contractions while the potentials are being measured.
- ▶ Note that this sequence may be repeated up to four times.
- ▶ When the procedure is complete, remove the electrodes and clean the skin where the electrode was applied. Apply pressure for 1 to 2 min to control any bleeding. Observe electrode sites for bleeding, hematoma, or inflammation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ If residual pain is noted after the procedure, instruct the patient to apply warm compresses and to take analgesics, as ordered.
- ▶ Instruct the patient to resume usual diet, medication, and activity, as directed by the HCP.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include acetylcholine receptor antibody, biopsy muscle, CSF analysis, CT brain, CK, ENG, evoked brain potentials (SER, VER), MRI brain, plethysmography, and PET brain.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Electromyography, Pelvic Floor Sphincter

SYNONYM/ACRONYM: Electrodiagnostic study, rectal electromyography.

COMMON USE: To assess urinary sphincter electrical activity to assist with diagnosis of urinary incontinence.

AREA OF APPLICATION: Sphincter muscles.

CONTRAST: None.

DESCRIPTION: Pelvic floor sphincter electromyography, also known as rectal electromyography, is performed to measure electrical activity of the external urinary sphincter. This procedure, often done in conjunction with cystometry and voiding urethrography as part of a full urodynamic study, helps to diagnose neuromuscular dysfunction and incontinence.

This procedure is contraindicated for

-  Patients with bleeding disorders **because the puncture sites may not stop bleeding.**

INDICATIONS

Evaluate neuromuscular dysfunction and incontinence

POTENTIAL DIAGNOSIS

Normal findings in

- Normal urinary and anal sphincter muscle function; increased electromyographic signals during the filling of the urinary bladder and at the conclusion of voiding; absence of signals during the actual voiding; no incontinence

Abnormal findings in

- Neuromuscular dysfunction of lower urinary sphincter, pelvic

floor muscle dysfunction of the anal sphincter

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Age-related decreases in electrical activity.
- Medications such as muscle relaxants, cholinergics, and anticholinergics.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- **Patient Teaching:** Inform the patient this procedure can assist in measuring the electrical activity of the pelvic floor muscles.

- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure. Warn the patient the procedure may be uncomfortable, but an analgesic or sedative will be administered. Assure the patient the pain is minimal during the catheter insertion. Inform the patient the procedure is performed in a special laboratory by a health-care provider (HCP) and takes about 30 min to complete.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Assess for ability to comply with directions given for exercising during the test.
- ▶ Under medical direction, the patient should avoid muscle relaxants, cholinergics, and anticholinergics for 3 to 6 days before the test.
- ▶ Instruct the patient to abstain from smoking and drinking caffeine-containing beverages for 3 hr before the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluid, tobacco, and medication restrictions and pretesting preparations.
- ▶ Record baseline vital signs.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Place the patient in a supine position on the examining table and place a drape over the patient, exposing the perianal area.
- ▶ Ask the patient to remain very still and relaxed and to cooperate when instructed to contract muscles during the procedure.
- ▶ Two skin electrodes are positioned slightly to the left and right of the perianal area and a grounding electrode is placed on the thigh.
- ▶ If needle electrodes are used, they are inserted into the muscle surrounding the urethra.
- ▶ Muscle activity signals are recorded as waves, which are interpreted for number and configurations in diagnosing urinary abnormalities.
- ▶ An indwelling urinary catheter is inserted, and the bulbocavernosus reflex is tested; the patient is instructed to cough while the catheter is gently pulled.
- ▶ Voluntary control is tested by requesting the patient to contract and relax the muscle. Electrical activity is recorded during this period of relaxation with the bladder empty.
- ▶ The bladder is filled with sterile water at a rate of 100 mL/min while the electrical activity during filling is recorded.
- ▶ The catheter is removed; the patient is then placed in a position to void and is asked to urinate and empty the full bladder. This voluntary urination is then recorded until completed. The complete procedure includes recordings of electrical signals before, during, and at the end of urination.

INTRATEST:

Potential Complications:

Complications are rare but include bleeding **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners** and urinary infection **related to use of a catheter.**

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting HCP, who will discuss the results with the patient.

- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary among facilities.
- ▶ Instruct the patient to increase fluid intake unless contraindicated.
- ▶ If tested with needle electrodes, warn female patients to expect hematuria after the first voiding.
- ▶ Advise the patient to report symptoms of urethral irritation, such as dysuria, persistent or prolonged hematuria, and urinary frequency.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss

the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CT pelvis, cystometry, cystoscopy, cystourethrography voiding, IVP, and US bladder.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Electroneurography

SYNONYM/ACRONYM: Electrodiagnostic study, nerve conduction study, ENG.

COMMON USE: To assess peripheral nerve conduction to assist in the diagnosis of diseases such as diabetic neuropathy and muscular dystrophy.

AREA OF APPLICATION: Muscles.

CONTRAST: None.

DESCRIPTION: Electroneurography (ENG) is performed to identify peripheral nerve injury, to differentiate primary peripheral nerve pathology from muscular injury, and to monitor response of the nerve injury to treatment. A stimulus is applied through a surface electrode over a nerve. After a nerve is electrically stimulated

proximally, the time for the impulse to travel to a second or distal site is measured. Because the conduction study of a nerve can vary from nerve to nerve, it is important to compare the results of the affected side to those of the contralateral side. The results of the stimulation are shown on a monitor, but the actual velocity

must be calculated by dividing the distance in meters between the stimulation point and the response point by the time between the stimulus and response. Traumatic nerve transection, contusion, or neuropathy will usually cause maximal slowing of conduction velocity in the affected side compared with that in the normal side. A velocity that is greater than normal does not indicate a pathological condition. This test is usually performed in conjunction with electromyography in a combined test called electromyoneurography.

This procedure is contraindicated for

-  Patients with a bleeding disorder when performed in addition to electromyography.

INDICATIONS

Confirm diagnosis of peripheral nerve damage or trauma

POTENTIAL DIAGNOSIS

Normal findings in

- No evidence of peripheral nerve injury or disease. Variable readings depend on the nerve being tested. For patients age 3 yr and older, the maximum conduction velocity is 40 to 80 milliseconds; for infants and the elderly, the values are divided by 2.

Abnormal findings in

- Carpal tunnel syndrome
- Diabetic neuropathy
- Guillain-Barré syndrome
- Herniated disk disease
- Muscular dystrophy
- Myasthenia gravis
- Poliomyelitis
- Tarsal tunnel syndrome indicated by decreased conduction time
- Thoracic outlet syndrome

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Age-related decreases in electrical activity.
- Poor electrode conduction or failure to obtain contralateral values for comparison.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- **Patient Teaching:** Inform the patient this procedure is performed to measure the electrical activity of the muscles.
- Obtain a history of the patient's complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics.
- Obtain a history of the patient's neuromuscular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain related to the procedure and inform the patient the procedure may be uncomfortable because of a mild electrical shock. Advise the patient that the electrical shock is brief and is not harmful. Inform the patient the procedure is performed in a special laboratory by a health-care provider (HCP) and takes approximately 15 min to complete but can take longer depending on the patient's condition.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Place the patient in a supine or sitting position, depending on the location of the muscle to be tested.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Use clippers to remove hair from the site if appropriate, and cleanse the skin thoroughly with alcohol pads.
- ▶ Apply electrode gel and place a recording electrode at a known distance from the stimulation point. Measure the distance between the stimulation point and the site of the recording electrode in centimeters.
- ▶ Place a reference electrode nearby on the skin surface.
- ▶ The nerve is electrically stimulated by a shock-emitter device; the time between nerve impulse and electrical contraction, measured in milliseconds (distal latency), is shown on a monitor.
- ▶ The nerve is also electrically stimulated at a location proximal to the area of suspected injury or disease.
- ▶ The time required for the impulse to travel from the stimulation site to location of the muscle contraction (total latency) is recorded in milliseconds.

- ▶ Calculate the conduction velocity. The conduction velocity is converted to meters per second (m/sec) and computed using the following equation:

Conduction velocity (m/sec) = [distance (m)] / [total latency – distal latency]
- ▶ When the procedure is complete, remove the electrodes and clean the skin where the electrodes were applied.
- ▶ Monitor electrode sites for inflammation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ If residual pain is noted after the procedure, instruct the patient to apply warm compresses and to take analgesics, as ordered.
- ▶ Instruct the patient to resume usual diet, medication, and activity, as directed by the HCP.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include acetylcholine receptor antibody, biopsy muscle, CK, EMG, evoked brain potentials (SER, VER), fluorescein angiography, fundus photography, glucose, glycated hemoglobin, insulin, microalbumin, and plethysmography.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Endoscopy, Sinus

SYNONYM/ACRONYM: N/A.

COMMON USE: To facilitate diagnosis and treatment of recurring sinus infections or infections resulting from unresolved sinus infection, including incursion into the brain, eye orbit, or eyeball.

AREA OF APPLICATION: Sinuses.

CONTRAST: N/A

DESCRIPTION: Sinus endoscopy, done with a narrow flexible tube, is used to help diagnose damage to the sinuses, nose, and throat. The tube contains an optical device with a magnifying lens with a bright light; the tube is inserted through the nose and threaded through the sinuses to the throat. A camera, monitor, or other viewing device is connected to the endoscope to record areas being examined. Sinus endoscopy helps to diagnose structural defects (e.g., polyps or other abnormal growths), damage, and acute or recurring infection to the nose, sinuses, and throat. The procedure is usually done in a health-care provider's (HCP's) office, but if done as a surgical procedure, the endoscope may be used to remove polyps from the nose or throat.

This procedure is contraindicated for: N/A

INDICATIONS

- Nasal obstruction
- Recurrent sinusitis

POTENTIAL DIAGNOSIS

Normal findings in

- Normal soft tissue appearance

Abnormal findings in

- Foreign bodies in the nose
- Growths in the nasal passages
- Polyps
- Sinusitis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status may interfere with the test results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in locating and treating infection of the sinus or surrounding areas.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's respiratory system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate.
- ▶ Review the procedure with the patient. Inform the patient that the procedure is usually done with the patient awake and seated upright in a chair. Address concerns about pain and explain that a local anesthetic spray or liquid may be applied to the throat to ease with insertion of the endoscope. Inform the patient that the procedure is usually performed in the office of an HCP and takes about 10 minutes.

▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Bleeding; cerebrospinal fluid leakage from the ethmoid sinus

- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Seat the patient comfortably. Instill ordered topical anesthetic in the throat, as ordered, and allow time for it to work.

- ▶ Observe that the endoscope is inserted and the structures inside the nose are examined.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection, if cultures are to be obtained on aspirated sinus material.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to wait until the numbness in the throat wears off before attempting to eat or drink following the procedure.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CT brain.
- ▶ Refer to the Respiratory System table at the end of the book for related tests by body system.

Eosinophil Count

SYNONYM/ACRONYM: Eos count, total eosinophil count.

COMMON USE: To assist in diagnosing conditions related to immune response such as asthma, dermatitis, and hay fever. Also used to assist in identification of parasitic infections.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Manual count using eosinophil stain and hemocytometer or automated analyzer)

Absolute count: 50 to 500 cells/microL [SI units (0.05–0.5 × 10⁹/L)]

Relative percentage: 1% to 4%

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Eosinophils are released and migrate to inflammatory sites in response to numerous environmental, chemical/drug, or immune-mediated triggers. T cells, mast cells, and macrophages release cytokines like interleukin-3 (IL3), interleukin-5 (IL5), granulocyte/macrophage colony-stimulating factor, and chemokines like the eotaxins, which can result in the activation of eosinophils.

- Addison's disease (*most commonly related to autoimmune destruction of adrenal glands*)
- Allergy
- Asthma
- Cancer
- Dermatitis
- Drug reactions
- Eczema
- Hay fever
- Hodgkin's disease
- Hypereosinophilic syndrome (rare and idiopathic)

- Löffler's syndrome (*pulmonary eosinophilia due to allergic reaction or infection from a fungus or parasite*)
- Myeloproliferative disorders (*related to abnormal changes in the bone marrow*)
- Parasitic infection (visceral larva migrans)
- Rheumatoid arthritis (*possibly related to medications used in therapy*)
- Rhinitis
- Sarcoidosis
- Splenectomy
- Tuberculosis

Decreased in

- Aplastic anemia (*bone marrow failure*)
- Eclampsia (*shift to the left; relative to significant production of neutrophils*)
- Infections (*shift to the left; relative to significant production of neutrophils*)
- Stress (*release of cortisol suppresses eosinophils*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Erythrocyte Protoporphyrin, Free

SYNONYM/ACRONYM: Free erythrocyte protoporphyrin (FEP).

COMMON USE: To assist in diagnosing anemias related to chronic disease, hemolysis, iron deficiency, and lead toxicity.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA), royal blue-top (EDTA), or a pink-top (EDTA) tube.

NORMAL FINDINGS: (Method: Fluorometry)

Conventional Units	SI Units (Conventional Units × 0.0178)
<i>Adult</i>	
Male	
Less than 30 mcg/dL	Less than 0.534 micromol/L
Female	
Less than 40 mcg/dL	Less than 0.712 micromol/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Anemia of chronic disease (*related to accumulation of protoporphyrin in the absence of available iron*)
- Conditions with marked erythropoiesis (e.g., hemolytic anemias) (*related to increased cell destruction*)

- Erythropoietic protoporphyria (*related to abnormal increased secretion*)
- Iron-deficiency anemias (*related to accumulation of protoporphyrin in the absence of available iron*)
- Lead poisoning (*possibly related to inactivation of enzymes involved in iron binding or transfer*)
- Some sideroblastic anemias

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Erythrocyte Sedimentation Rate

SYNONYM/ACRONYM: Sed rate, ESR.

COMMON USE: To assist in diagnosing acute infection in diseases such as tissue necrosis, chronic infection, and acute inflammation.

SPECIMEN: Whole blood (5 mL) collected in a lavender-top (EDTA) tube for the modified Westergren method or a gray-top (3.8% sodium citrate) tube for the original Westergren method.

NORMAL FINDINGS: (Method: Westergren or modified Westergren)

Age	Male	Female
Newborn	0–2 mm/hr	0–2 mm/hr
Less than 50 yr	0–15 mm/hr	0–25 mm/hr
50 yr and older	0–20 mm/hr	0–30 mm/hr

DESCRIPTION: The erythrocyte sedimentation rate (ESR) is a measure of the rate of sedimentation of red blood cells (RBCs) in an anticoagulated whole blood sample over a specified period of time. The basis of the ESR test is the alteration of blood proteins by inflammatory and necrotic processes that cause the RBCs to stick together, become heavier, and rapidly settle at the bottom of a vertically held, calibrated tube over time. The most common promoter of rouleaux is an increase in circulating fibrinogen levels. In general, relatively little settling occurs in normal blood because normal RBCs do not form rouleaux and would not stack together. The sedimentation rate is proportional to the size or mass of the falling RBCs and is inversely proportional to plasma viscosity. The test is a nonspecific indicator of disease but is fairly sensitive and is frequently the earliest indicator of widespread inflammatory reaction due to infection or autoimmune disorders. Prolonged elevations are also present in malignant disease. The ESR can also be used to monitor the course of a disease and the effectiveness of therapy. The most commonly used method to measure the ESR is the Westergren (or modified Westergren) method.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of acute infection, such as tuberculosis or tissue necrosis
- Assist in the diagnosis of acute inflammatory processes
- Assist in the diagnosis of chronic infections
- Assist in the diagnosis of rheumatoid or autoimmune disorders
- Assist in the diagnosis of temporal arthritis and polymyalgia rheumatica
- Monitor inflammatory and malignant disease

POTENTIAL DIAGNOSIS

Increased in

Increased rouleaux formation is associated with increased levels of fibrinogen and/or production of cytokines and other acute-phase reactant proteins in response to inflammation. Anemia of chronic disease as well as acute anemia influence the ESR because the decreased number of RBCs falls faster with the relatively increased plasma volume.

- Acute myocardial infarction
- Anemia (*RBCs fall faster with increased plasma volume*)
- Carcinoma
- Cat scratch fever (*Bartonella henselae*)

- Collagen diseases, including systemic lupus erythematosus (SLE)
- Crohn's disease (*due to anemia or related to acute-phase reactant proteins*)
- Elevated blood glucose (*hyperglycemia in older patients can induce production of cytokines responsible for the inflammatory response; hyperglycemia related to insulin resistance can cause hepatocytes to shift protein synthesis from albumin to production of acute-phase reactant proteins*)
- Endocarditis
- Heavy metal poisoning (*related to anemia affecting size and shape of RBCs*)
- Increased plasma protein level (*RBCs fall faster with increased plasma viscosity*)
- Infections (e.g., pneumonia, syphilis)
- Inflammatory diseases
- Lymphoma
- Lymphosarcoma
- Multiple myeloma (*RBCs fall faster with increased plasma viscosity*)
- Nephritis
- Pregnancy (*related to anemia*)
- Pulmonary embolism
- Rheumatic fever
- Rheumatoid arthritis
- Subacute bacterial endocarditis
- Temporal arteritis
- Toxemia
- Tuberculosis
- Waldenström's macroglobulinemia (*RBCs fall faster with increased plasma viscosity*)

Decreased in

- Conditions resulting in high hemoglobin and RBC count

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Some drugs cause an SLE-like syndrome that results in a physiological

increase in ESR. These include anti-convulsants, hydrazine derivatives, nitrofurantoin, procainamide, and quinidine. Other drugs that may cause an increased ESR include acetylsalicylic acid, cephalothin, cephapirin, cyclosporin A, dextran, and oral contraceptives.

- Drugs that may cause a decrease in ESR include aurothiomalate, corticotropin, cortisone, dexamethasone, methotrexate, minocycline, NSAIDs, penicillamine, prednisolone, prednisone, quinine, sulfasalazine, tamoxifen, and trimethoprim.
- Menstruation may cause falsely increased test results.
- Prolonged tourniquet constriction around the arm may cause hemoconcentration and falsely low values.
- The Westergren and modified Westergren methods are affected by heparin, which causes a false elevation in values.
- Bubbles in the Westergren tube or pipette, or tilting the measurement column more than 3° from vertical, will falsely increase the values.
- Movement or vibration of the surface on which the test is being conducted will affect the results.
- Inaccurate timing or a delay in performing the test once the specimen has been collected will invalidate test results.
- Specimens that are clotted, hemolyzed, or insufficient in volume should be rejected for analysis.
- The test should be performed within 4 hr of collection when the specimen has been stored at room temperature; delays in testing may result in decreased values. If a delay in testing is anticipated, refrigerate the sample at 2°C to 4°C; stability at refrigerated temperature is reported to be extended up to 12 hr. Refrigerated specimens should be brought to room temperature before testing.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to inadequate defense mechanism; insufficient nutrition; chronic disease; IV access devices; pathogen exposure; indwelling urinary catheter; compromised immune system; mechanical intubation</i>)	Fever; increased heart rate; increased blood pressure; shaking; chills; mottled skin; lethargy; fatigue; swelling; edema; pain; localized pressure; diaphoresis; night sweats; confusion; vomiting; nausea; headache; cloudy, foul smelling urine with sediment; elevated WBC; elevated ESR	Promote good hygiene; assist with hygiene as needed; administer prescribed antibiotics, antipyretics; provide cooling measures; administer prescribed IV fluids; monitor vital signs and trend temperatures; encourage oral fluids; adhere to standard or universal precautions; isolate as appropriate; obtain cultures as ordered; encourage use of lightweight clothing and bedding; assess nutritional status and provide supplements as needed; assess for exposure to infections; monitor sputum color and viscosity; assess urine characteristics (color, clarity); monitor and trend WBC and ESR rate; monitor for symptoms of infection (redness, swelling, purulent drainage, pain from wound or incisions); provide aseptic tracheal care; perform dressing changes with sterile or aseptic technique; perform vigilant hand hygiene
Tissue integrity (<i>Related to infection</i>)	Area on the skin that is warm or tender to touch; skin that turns red, purple, or black; localized pain; swelling of affected area; elevated WBC; elevated ESR	Perform baseline skin assessment and frequent re-assessment using a standardized scale (Braden); monitor and note the presence of herpes lesions; encourage the use of hypoallergenic soap and lanolin products, pat rather than rub skin dry; avoid bed

Problem	Signs & Symptoms	Interventions
<p>Nutrition (<i>Related to nutrition, to inability to digest foods, metabolize foods, ingest foods; refusal to eat; increased metabolic needs associated with disease process; lack of understanding</i>)</p>	<p>Unintended weight loss; current weight is 20% below ideal weight; pale dry skin; dry mucous membranes; documented inadequate caloric intake; subcutaneous tissue loss; hair pulls out easily; paresthesia</p>	<p>wrinkles; ensure sheets are soft and gentle on skin; encourage adequate nutrition; administer prescribed vitamin supplements; encourage and assist range of motion; assess the characteristics of a wound (color, size, length, width, depth, drainage, and odor); monitor for fever; identify the cause of the tissue damage; monitor and trend WBC and ESR</p> <p>Record accurate daily weight at the same time each day with the same scale; obtain an accurate nutritional history; assess attitude toward eating; promote a dietary consult to evaluate current eating habits and best method of nutritional supplementation; develop short-term and long-term eating strategies; monitor nutritional laboratory values such as albumin; assess swallowing ability; encourage cultural home foods; provide a pleasant environment for eating; alter food seasoning to enhance flavor; provide parenteral or enteral nutrition as prescribed</p>
<p>Activity (<i>Related to inflammation; infection; altered tissue perfusion; deconditioned state</i>)</p>	<p>Weakness; verbal report of fatigue; altered sleep pattern; altered blood pressure, heart rate, or respiratory rate in response to activity; oxygen desaturation with activity</p>	<p>Assess current level of activity and weakness; identify the patient's perception of the cause of weakness; assess the need for the use of assistive devices; observe and document the patient's tolerance to activity; provide ordered oxygen; limit energy expenditure to necessary activities</p>

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of inflammation.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of infectious, autoimmune, or neoplastic diseases.
- ▶ Obtain a history of the patient's cardiovascular, hematopoietic, immune, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Perform a venipuncture; collect the specimen in a 5-mL gray-top (sodium citrate) tube if

- the Westergren method will be used. Collect the specimen in a 5-mL purple-top (EDTA) tube if the modified Westergren method will be used.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services, as appropriate.
- ▶ Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org) or for the Arthritis Foundation (www.arthritis.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:**Knowledge**

- ▶ States understanding of the signs and symptoms of infection including what to report and when to report concerns
- ▶ States understanding of follow-up ESR to monitor the effectiveness of therapeutic interventions

kidney but do not disappear completely. It is thought that small amounts of EPO may be produced by the liver. Erythropoiesis is regulated by EPO and tissue Po_2 . When Po_2 is normal, EPO levels decrease; when Po_2 falls, EPO secretion occurs and EPO levels increase.

This procedure is contraindicated: N/A

INDICATIONS

- Assist in assessment of anemia of end-stage renal disease
- Assist in the diagnosis of EPO-producing tumors
- Evaluate the presence of rare anemias
- Monitor patients receiving EPO therapy

POTENTIAL DIAGNOSIS

Increased in

- After moderate bleeding in an otherwise healthy patient (*related to loss of RBCs, which stimulates production*)
- AIDS (*related to anemia, which stimulates production*)
- Anemias (e.g., hemolytic, iron deficiency, megaloblastic) (*related to low RBC count, which stimulates production*)
- Hepatoma (*related to EPO-producing tumors*)
- Kidney transplant rejection (*15% of cases respond with an exaggerated secretion of EPO and a transient post-transplantation erythrocytosis*)
- Nephroblastoma (*related to EPO-producing tumors*)
- Pheochromocytoma (*related to EPO-producing tumors*)
- Polycystic kidney disease (*related to EPO-producing tumors or cysts*)

- Pregnancy (*related to anemia of pregnancy, which stimulates production*)
- Secondary polycythemia where low oxygen levels stimulate production (*high-altitude hypoxia, chronic obstructive pulmonary disease, pulmonary fibrosis*)

Decreased in

- Chemotherapy (*related to therapy, which can be toxic to the kidney*)
- Primary polycythemia (*related to feedback loop response to elevated RBC count*)
- Renal failure (*related to decreased production and excessive loss through excretion by damaged kidneys*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs, hormones, and other substances that may increase EPO levels include adrenocorticotrophic hormone (ACTH), anabolic steroids, androgens, angiotensin, epinephrine, daunorubicin, fenoterol, growth hormone, and thyroid-stimulating hormone (TSH).
- Phlebotomy may increase EPO levels.
- Drugs that may decrease EPO levels include amphotericin B, cisplatin, enalapril, estrogens, furosemide, and theophylline.
- Blood transfusions may also decrease EPO levels.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluation of anemia.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics,

- initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, BUN, CBC, CBC hematocrit, CBC hemoglobin, CBC RBC count, CBC RBC indices, CBC RBC morphology and inclusions, CT renal, creatinine, creatinine clearance, ferritin, iron/TIBC, microalbumin, retrograde ureteropyelography, US kidney, and vitamin B₁₂.
- ▶ Refer to the Hematopoietic and Genitourinary systems tables at the end of the book for related tests by body system.

Esophageal Manometry

SYNONYM/ACRONYM: Esophageal function study, esophageal acid study (Tuttle test), acid reflux test, Bernstein test (acid perfusion), esophageal motility study.

COMMON USE: To evaluate potential ineffectiveness of the esophageal muscle and structure in swallowing, vomiting, and regurgitation in diseases such as scleroderma, infection, and gastric esophageal reflux.

AREA OF APPLICATION: Esophagus.

CONTRAST: None

DESCRIPTION: Esophageal manometry (EM) consists of a group of invasive studies performed to assist in diagnosing abnormalities of esophageal muscle function and esophageal structure. These studies measure esophageal pressure, the effects of gastric acid in the esophagus, lower esophageal sphincter pressure, and motility patterns that result during swallowing. EM can be used to document and quantify gastroesophageal reflux disease (GERD). It is indicated when a patient is experiencing difficulty swallowing, heartburn, regurgitation, or vomiting or has chest pain for which no diagnosis has been found. Tests performed in combination with EM include the acid reflux, acid clearing, and acid perfusion (Bernstein) tests.

This procedure is contraindicated for

-  Patients with unstable cardiopulmonary status, blood coagulation defects, recent gastrointestinal surgery, esophageal varices, or bleeding.

INDICATIONS

- Aid in the diagnosis of achalasia, evidenced by increased pressure in EM

- Aid in the diagnosis of achalasia in children, evidenced by decreased pressure in EM
- Aid in the diagnosis of esophageal scleroderma, evidenced by decreased pressure in EM
- Aid in the diagnosis of esophagitis, evidenced by decreased motility
- Aid in the diagnosis of GERD, evidenced by low pressure in EM, decreased pH in acidity test, and pain in acid reflux and perfusion tests
- Differentiate between esophagitis or cardiac condition as the cause of epigastric pain
- Evaluate pyrosis and dysphagia to determine if the cause is GERD or esophagitis

POTENTIAL DIAGNOSIS

Normal findings in

- Acid clearing: fewer than 10 swallows
- Acid perfusion: no GERD
- Acid reflux: no regurgitation into the esophagus
- Bernstein test: negative
- Esophageal secretions: pH 5 to 6
- Esophageal sphincter pressure: 10 to 20 mm Hg

Abnormal findings in

- Achalasia (sphincter pressure of 50 mm Hg)
- Chalasia

- Esophageal scleroderma
- Esophagitis
- GERD (sphincter pressure of 0 to 5 mm Hg, pH of 1 to 3)
- Hiatal hernia
- Progressive systemic sclerosis (scleroderma)
- Spasms

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Administration of medications (e.g., sedatives, antacids, anticholinergics, cholinergics, corticosteroids) that can change pH or relax the sphincter muscle, causing inaccurate results.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the esophagus.
- ▶ Obtain a history of the patient's complaints, including a list of known allergies, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent barium or other radiological contrast procedures. Ensure that barium studies were performed more than 4 days before the EM.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test; there may be moments of discomfort and gagging when the scope is inserted, but there are no complications resulting from the procedure; and the throat will be anesthetized with a spray or swab. Inform the patient that he or she will not be able to speak during the procedure but breathing will not be affected. Inform the patient that the procedure is performed in an endoscopy suite by a health-care provider (HCP), under local anesthesia, and takes approximately 30 to 45 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Instruct the patient to remove dentures and eyewear.
- ▶ Under medical direction, the patient should withhold medications for 24 hr before the study; special arrangements may be necessary for diabetic patients.
- ▶ Instruct the patient to fast and restrict fluids for 6 to 8 hr prior to the procedure. Protocols may vary among facilities.
- ▶ Obtain and record baseline vital signs.

- ▶ Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Potential Complications:

Establishing an IV site and injection of contrast medium by catheter are invasive procedures. Complications are rare but do include risk for bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**, hematoma **related to blood leakage into the tissue following needle insertion**, or infection **that might occur if bacteria from the skin surface is introduced at the puncture site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluids, and medication restrictions and pretesting preparations for at least 6 to 8 hr prior to the procedure.
- ▶ Ensure the patient has removed dentures and eyewear prior to the procedure.
- ▶ Avoid using morphine sulfate in patients with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, or emergency medications.
- ▶ Spray or swab the oropharynx with a topical local anesthetic.

- ▶ Provide an emesis basin for the increased saliva and encourage the patient to spit out saliva since the gag reflex may be impaired.
- ▶ Monitor the patient for complications related to the procedure (e.g., aspiration of stomach contents into the lungs, dyspnea, tachypnea, adventitious sounds).
- ▶ Suction the mouth, pharynx, and trachea, and administer oxygen as ordered.

Esophageal Manometry

- ▶ One or more small tubes are inserted through the nose into the esophagus and stomach.
- ▶ A small transducer is attached to the ends of the tubes to measure lower esophageal sphincter pressure, intraluminal pressures, and regularity and duration of peristaltic contractions.
- ▶ Instruct the patient to swallow small amounts of water or flavored gelatin.

Esophageal Acid and Clearing (Tuttle Test)

- ▶ With the tube in place, a pH electrode probe is inserted into the esophagus with Valsalva maneuvers performed to stimulate reflux of stomach contents into the esophagus.
- ▶ If acid reflux is absent, 100 mL of 0.1% hydrochloric acid is instilled into the stomach during a 3-min period, and the pH measurement is repeated.
- ▶ To determine acid clearing, hydrochloric acid is instilled into the esophagus and the patient is asked to swallow while the probe measures the pH.

Acid Perfusion (Bernstein Test)

- ▶ A catheter is inserted through the nose into the esophagus, and the patient is asked to inform the HCP when pain is experienced.
- ▶ Normal saline solution is allowed to drip into the catheter at about 10 mL/min. Then hydrochloric acid is allowed to drip into the catheter.
- ▶ Pain experienced when the hydrochloric acid is instilled determines the presence of an esophageal abnormality. If no pain is experienced, symptoms are the result of some other condition.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Monitor the patient for signs of respiratory depression (less than 15 respirations/min) every 15 min for 2 hr. Resuscitation equipment should be available.
- ▶ **Observe the patient for indications of perforation:** painful swallowing with neck movement, substernal pain with respiration, shoulder pain, dyspnea, abdominal or back pain, cyanosis, and fever.
- ▶ Instruct the patient not to eat or drink until the gag reflex returns and then to eat lightly for 12 to 24 hr.
- ▶ Instruct the patient to resume usual activity, medication, and diet 24 hr after the examination or as tolerated, as directed by the HCP.
- ▶ Inform the patient to expect some throat soreness and possible hoarseness. Advise the patient to use warm gargles, lozenges, or ice packs to the neck and to drink cool fluids to alleviate throat discomfort.
- ▶ Emphasize that any severe pain, fever, difficulty breathing, or expectoration of blood must be reported to the HCP immediately.

- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ANA, barium swallow, biopsy skin, capsule endoscopy, chest x-ray, CT thoracic, esophagogastroduodenoscopy, fecal analysis, gastric emptying scan, GERD scan, lung perfusion scan, mediastinoscopy, and upper GI series.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Esophagogastroduodenoscopy

SYNONYM/ACRONYM: Esophagoscopy, gastroscopy, upper GI endoscopy, EGD.

COMMON USE: To visualize and assess the esophagus, stomach, and upper portion of the duodenum to assist in diagnosis of bleeding, ulcers, inflammation, tumor, and cancer.

AREA OF APPLICATION: Esophagus, stomach, and upper duodenum.

CONTRAST: Done without contrast.

DESCRIPTION: Esophagogastroduodenoscopy (EGD) allows direct visualization of the upper gastrointestinal (GI) tract mucosa, which includes the esophagus, stomach, and upper portion of the duodenum, by means of a flexible endoscope. The standard flexible fiberoptic endoscope contains three channels that allow passage of the instruments needed to perform therapeutic or diagnostic procedures, such as biopsies or cytology washings. The endoscope, a multichannel instrument, allows visualization of the GI tract linings, insufflation of air, aspiration of fluid, removal of foreign bodies by suction or by snare or forceps, and passage of a laser beam for obliteration of abnormal tissue or control of bleeding. Direct visualization yields greater diagnostic data than is possible through radiological procedures, and therefore EGD is rapidly replacing upper GI series as the diagnostic procedure of choice.

This procedure is contraindicated for

- ◆ Patients who have had surgery involving the stomach or duodenum, which can make locating the duodenal papilla difficult.
- ◆ Patients with a bleeding disorder.
- ◆ Patients with unstable cardiopulmonary status, blood coagulation defects, or cholangitis, unless the patient received prophylactic antibiotic therapy before the test (otherwise the examination must be rescheduled).
- ◆ Patients with known aortic arch aneurysm, large esophageal Zenker's diverticulum, recent

gastrointestinal (GI) surgery, esophageal varices, or known esophageal perforation.

INDICATIONS

- Assist in differentiating between benign and neoplastic tumors
- Detect gastric or duodenal ulcers
- Detect upper GI inflammatory disease
- Determine the presence and location of acute upper GI bleeding
- Evaluate the extent of esophageal injury after ingestion of chemicals
- Evaluate stomach or duodenum after surgical procedures
- Evaluate suspected gastric outlet obstruction
- Identify tissue abnormalities and obtain biopsy specimens
- Investigate the cause of dysphagia, dyspepsia, and epigastric pain

POTENTIAL DIAGNOSIS

Normal findings in

- Esophageal mucosa is normally yellow-pink. At about 9 in. from the incisor teeth, a pulsation indicates the location of the aortic arch. The gastric mucosa is orange-red and contains rugae. The proximal duodenum is reddish and contains a few longitudinal folds, whereas the distal duodenum has circular folds lined with villi. No abnormal structures or functions are observed in the esophagus, stomach, or duodenum.

Abnormal findings in

- Acute and chronic gastric and duodenal ulcers
- Diverticular disease
- Duodenitis
- Esophageal varices
- Esophageal or pyloric stenosis
- Esophagitis or strictures
- Gastritis
- Hiatal hernia

- Mallory-Weiss syndrome
- Tumors (benign or malignant)

CRITICAL FINDINGS

- Presence and location of acute GI bleed

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or food in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the esophagus and gastrointestinal tract.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent barium or other radiological contrast procedures ordered. Ensure that barium studies are performed after this study.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort, but the throat will be anesthetized with a spray or swab.

Inform the patient that he or she will not be able to speak during the procedure, but breathing will not be affected. Inform the patient that the procedure is performed in a GI laboratory or radiology department, usually by an HCP and support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution's policy.
- ▶ Inform the patient that dentures and eyewear will be removed before the test.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

May include bleeding and cardiac arrhythmias.

- ▶ Ensure the patient has complied with dietary and medication restrictions and

pretesting preparations for at least 8 hr prior to the procedure.

- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Assess for completion of bowel preparation according to the institution's procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Obtain and record baseline vital signs.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications. Administer ordered sedation.
- ▶ Spray or swab the oropharynx with a topical local anesthetic.
- ▶ Provide an emesis basin for the increased saliva and encourage the patient to spit out the saliva because the gag reflex may be impaired.
- ▶ Place the patient on an examination table in the left lateral decubitus position with the neck slightly flexed forward.
- ▶ The endoscope is passed through the mouth with a dental suction device in place to drain secretions. A side-viewing flexible, fiberoptic endoscope is advanced, and visualization of the GI tract is started.
- ▶ Air is insufflated to distend the upper GI tract, as needed. Biopsy specimens are obtained and/or endoscopic surgery is performed.

- ▶ Promptly transport the specimens to the laboratory for processing and analysis.
- ▶ At the end of the procedure, excess air and secretions are aspirated through the scope and the endoscope is removed.
- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe the patient for indications of esophageal perforation (i.e., painful swallowing with neck movement, substernal pain with respiration, shoulder pain or dyspnea, abdominal or back pain, cyanosis, or fever).
- ▶ Do not allow the patient to eat or drink until the gag reflex returns; then allow the patient to eat lightly for 12 to 24 hr.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered by the HCP. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Instruct the patient to resume usual activity and diet in 24 hr or as tolerated after the examination, as directed by the HCP.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Inform the patient that he or she may experience some throat soreness and

hoarseness. Instruct patient to treat throat discomfort with lozenges and warm gargles when the gag reflex returns.

- ▶ Inform the patient that any belching, bloating, or flatulence is the result of air insufflation and is temporary.
- ▶ Instruct the patient to report any severe pain, fever, difficulty breathing, or expectoration of blood. Immediately report symptoms to the appropriate HCP.
- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include barium enema, barium swallow, capsule endoscopy, colonoscopy, CT abdomen, esophageal manometry, fecal analysis, gastric acid emptying scan, gastric fluid analysis and gastric acid stimulation test, gastrin and gastrin stimulation test, GI blood loss scan, *Helicobacter pylori*, MRI abdomen, proctosigmoidoscopy, US pelvis, and upper GI series.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Estradiol

SYNONYM/ACRONYM: E₂.

COMMON USE: To assist in diagnosing female fertility problems that may occur from tumor or ovarian failure.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 3.67)
6 mo–10 yr		
Male and female	Less than 15 pg/mL	Less than 55 pmol/L
11–15 yr		
Male	Less than 40 pg/mL	Less than 147 pmol/L
Female	10–300 pg/mL	37–1,100 pmol/L
Adult male	10–50 pg/mL	37–184 pmol/L
Adult female		
Early follicular phase	20–150 pg/mL	73–551 pmol/L
Late follicular phase	40–350 pg/mL	147–1,285 pmol/L
Midcycle peak	150–750 pg/mL	551–2,753 pmol/L
Luteal phase	30–450 pg/mL	110–1,652 pmol/L
Postmenopause	Less than 20 pg/mL	Less than 73 pmol/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Adrenal tumors (*related to overproduction by tumor cells*)
- Estrogen-producing tumors
- Feminization in children (*related to increased production*)
- Gynecomastia (*newborns may demonstrate swelling of breast tissue in response to maternal estrogens; somewhat common and transient in pubescent males*)
- Hepatic cirrhosis (*accumulation occurs due to lack of liver function*)

- Hyperthyroidism (*related to primary increases in estrogen or response to increased levels of sex hormone-binding globulin*)

Decreased in

- Ovarian failure (*resulting in lack of estrogen synthesis*)
- Primary and secondary hypogonadism (*related to lack of estrogen synthesis*)
- Turner's syndrome (*genetic abnormality in females in which there is only one X chromosome, resulting in varying degrees of underdeveloped sexual characteristics*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Evoked Brain Potentials

SYNONYM/ACRONYM: Brainstem auditory evoked potentials (BAEP), brainstem auditory evoked responses (BAER), EP studies.

COMMON USE: To assist in diagnosing sensory deficits related to nervous system lesions manifested by visual defects, hearing defects, neuropathies, and cognitive disorders.

AREA OF APPLICATION: Brain.

CONTRAST: None.

DESCRIPTION: Evoked brain potentials, also known as evoked potential (EP) responses, are electrophysiological studies performed to measure the brain's electrical responses to various visual, auditory, and somatosensory stimuli. EP studies help diagnose lesions of the nervous system by evaluating the integrity of the visual, somatosensory, and auditory nerve pathways. Three response types are measured: visual evoked response (VER), auditory brainstem response (ABR), and somatosensory evoked response (SER). The stimuli activate the nerve tracts that connect the stimulated (receptor) area with the cortical (visual and somatosensory) or midbrain (auditory) sensory area. A number of stimuli are given, and then responses are electronically displayed in waveforms, recorded, and computer analyzed. Abnormalities are determined by a delay in time, measured in milliseconds, between the stimulus and the response. This is known as *increased latency*. VER provides

information about visual pathway function to identify lesions of the optic nerves, optic tracts, and demyelinating diseases such as multiple sclerosis. ABR provides information about auditory pathways to identify hearing loss and lesions of the brainstem. SER provides information about the somatosensory pathways to identify lesions at various levels of the central nervous system (spinal cord and brain) and peripheral nerve disease. EP studies are especially useful in patients with problems and those unable to speak or respond to instructions during the test, because these studies do not require voluntary cooperation or participation in the activity. This allows collection of objective diagnostic information about visual or auditory disorders affecting infants and children and allows differentiation between organic brain and psychological disorders in adults. EP studies are also used to monitor the progression of or the effectiveness of treatment for deteriorating neurological diseases such as multiple sclerosis.

This procedure is contraindicated for: N/A

INDICATIONS

VER (potentials)

- Detect cryptic or past retrobulbar neuritis
- Detect lesions of the eye or optic nerves
- Detect neurological disorders such as multiple sclerosis, Parkinson's disease, and Huntington's chorea
- Evaluate binocularity in infants
- Evaluate optic pathway lesions and visual cortex defects

ABR (potentials)

- Detect abnormalities or lesions in the brainstem or auditory nerve areas
- Detect brainstem tumors and acoustic neuromas
- Screen or evaluate neonates, infants, children, and adults for auditory problems
- EP studies may be indicated when a child falls below growth chart norms

SER (potentials)

- Detect multiple sclerosis and Guillain-Barré syndrome
- Detect sensorimotor neuropathies and cervical pathology
- Evaluate spinal cord and brain injury and function
- Monitor sensory potentials to determine spinal cord function during a surgical procedure or medical regimen

ERP (potentials)

- Detect suspected psychosis or dementia
- Differentiate between organic brain disorder and cognitive function abnormality

POTENTIAL DIAGNOSIS

Normal findings in

- **VER and ABR:** Normal latency in recorded cortical and brainstem

waveforms depending on age, gender, and stature

- **ERP:** Normal recognition and attention span
- **SER:** No loss of consciousness or presence of weakness

Abnormal findings in

- **VER (potentials):**
P100 latencies (extended) confined to one eye suggest a lesion anterior to the optic chiasm.
Bilateral abnormal P100 latencies indicate multiple sclerosis, optic neuritis, retinopathies, spinocerebellar degeneration, sarcoidosis, Parkinson's disease, adrenoleukodystrophy, Huntington's chorea, or amblyopias.
- **ABR (potentials):**
Normal response at high intensities; wave V may occur slightly later. Earlier wave distortions suggest cochlear lesion.
Absent or late waves at high intensities; increased amplitude of wave V suggests retrocochlear lesion.
- **SER (potentials):**
Abnormal upper limb latencies suggest cervical spondylosis or intracerebral lesions.
Abnormal lower limb latencies suggest peripheral nerve root disease such as Guillain-Barré syndrome, multiple sclerosis, transverse myelitis, or traumatic spinal cord injuries.

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status. (*Note:* Significant behavioral problems may limit the ability to complete the test.)
- Improper placement of electrodes.
- Patient stress, which can affect brain chemistry, thus making it difficult to distinguish whether the results are due to the patient's

emotional reaction or to organic pathology.

- Extremely poor visual acuity, which can hinder accurate determination of VER.
- Severe hearing loss, which can interfere with accurate determination of ABR.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure measures electrical activity in the nervous system.
- ▶ Obtain a history of the patient's complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's neuromuscular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that the procedure is painless and harmless. Inform the patient that the procedure is performed in a special laboratory by a health-care provider (HCP) and takes approximately 30 min to 2 hr, depending on the type of studies required.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to clean the hair and to refrain from using hair sprays, creams, or solutions before the test.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient is able to relax; report any extreme anxiety or restlessness.
- ▶ Ensure that hair is clean and free of hair sprays, creams, or solutions.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

Visual Evoked Potentials

- ▶ Place the patient in a comfortable position about 1 m from the stimulation source. Attach electrodes to the occipital and vertex lobe areas and a reference electrode to the ear. A light-emitting stimulation or a checkerboard pattern is projected on a screen at a regulated speed. This procedure is done for each eye (with the opposite eye covered) as the patient looks at a dot on the screen without any change in the gaze while the stimuli are delivered. A computer interprets the brain's responses to the stimuli and records them in waveforms.

Auditory Evoked Potentials

- ▶ Place the patient in a comfortable position, and place the electrodes on the scalp at the vertex lobe area and on each earlobe. Earphones are placed on the patient's ears, and a clicking noise stimulus is delivered into one ear while a continuous tone is delivered to the opposite ear. Responses to the stimuli are recorded as waveforms for analysis.

Somatosensory Evoked Potentials

- ▶ Place the patient in a comfortable position, and place the electrodes at the nerve sites of the wrist, knee, and

ankle and on the scalp at the sensory cortex of the hemisphere on the opposite side (the electrode that picks up the response and delivers it to the recorder). Additional electrodes can be positioned at the cervical or lumbar vertebrae for upper or lower limb stimulation. The rate at which the electric shock stimulus is delivered to the nerve electrodes and travels to the brain is measured, computer analyzed, and recorded in waveforms for analysis. Both sides of the area being examined can be tested by switching the electrodes and repeating the procedure.

Event-Related Potentials

- Place the patient in a sitting position in a chair in a quiet room. Earphones are placed on the patient's ears and auditory cues administered. The patient is asked to push a button when the tones are recognized. Flashes of light are also used as visual cues, with the client pushing a button when cues are noted. Results are compared to normal EP waveforms for correct, incorrect, or absent responses.

POST-TEST:

- Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

- When the procedure is complete, remove the electrodes and clean the skin where the electrodes were applied.
- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include acetylcholine receptor antibody, Alzheimer's disease markers, biopsy muscle, CSF analysis, CT brain, CK, EEG, ENG, MRI brain, plethysmography, and PET brain.
- Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Exercise Stress Test

SYNONYM/ACRONYM: Exercise electrocardiogram, ECG, EKG, graded exercise tolerance test, stress testing, treadmill test.

COMMON USE: To assess cardiac function in relation to increased workload, evidenced by dysrhythmia or pain during exercise.

AREA OF APPLICATION: Heart.

CONTRAST: None.

DESCRIPTION: The exercise stress test is a noninvasive study to measure cardiac function during physical stress. Exercise electrocardiography is primarily useful in determining the extent of coronary artery occlusion by the heart's ability to meet the need for additional oxygen in response to the stress of exercising in a safe environment. The patient exercises on a treadmill or pedals a stationary bicycle to increase the heart rate to 80% to 90% of maximal heart rate determined by age and gender, known as the **target heart rate**. Every 2 to 3 min, the speed and/or grade of the treadmill is increased to yield an increment of stress. The patient's electrocardiogram (ECG) and blood pressure are monitored during the test. The test proceeds until the patient reaches the target heart rate or experiences chest pain or fatigue. The risks involved in the procedure are possible myocardial infarction (1 in 500) and death (1 in 10,000) in patients experiencing frequent angina episodes before the test. Although useful, this procedure is not as accurate as cardiac nuclear scans for diagnosing coronary artery disease (CAD).

For patients unable to complete the test, pharmacological stress testing can be done. Medications used to pharmacologically exercise the patient's heart include vasodilators such as dipyridamole and adenosine or dobutamine (which stimulates heart rate and pumping force). Stress testing should be discontinued when maximal performance has been reached or if certain criteria occur as noted in the Contraindications section. The patient's ECG and blood pressure

are monitored during the exercise phase. The test proceeds until the stimulated exercise portion is completed when a radiotracer, such as technetium-99m or sestamibi, is injected and images are taken by a gamma camera during the stimulated portion to compare with images taken at rest.

This procedure is contraindicated for

A variety of circumstances that may be considered absolute or relative depending on the facility's providers:

- Abnormal EKG changes causing symptoms **related to the possibility of stress-induced infarction.**
- Acute myocardial infarction (AMI) (within 2 days) **related to the possibility of stress-induced reinfarction.**
- Acute myocarditis **related to low stress tolerance.**
- Aortic dissection **related to the possibility of stress-induced tears and rupture.**
- Chest pain **related to the possibility of stress-induced infarction.**
- Heart failure with symptoms (e.g., shortness of breath) **related to low stress tolerance.**
- Mental or physical (e.g., severe leg claudication) impairment that prevents the patient from performing the required exercise.
- Significant hypertension or hypotension.
- Stenotic valvular disease with symptoms **related to low stress tolerance from having the heart work harder to pump blood through the narrow valve.**
- Very fast (tachyarrhythmias) or very slow (bradyarrhythmias) heart rate.

INDICATIONS

- Detect dysrhythmias during exercising, as evidenced by ECG changes
- Detect peripheral artery disease (PAD), as evidenced by leg pain or cramping during exercising
- Determine exercise-induced hypertension
- Evaluate cardiac function after myocardial infarction or cardiac surgery to determine safe exercise levels for cardiac rehabilitation as well as work limitations
- Evaluate effectiveness of medication regimens, such as antianginals or antiarrhythmics
- Evaluate suspected CAD in the presence of chest pain and other symptoms
- Screen for CAD in the absence of pain and other symptoms in patients at risk

POTENTIAL DIAGNOSIS

Normal findings in

- Normal heart rate during physical exercise. Heart rate and systolic blood pressure rise in direct proportion to workload and to metabolic oxygen demand, which is based on age and exercise protocol. Maximal heart rate for adults is normally 150 to 200 beats/min.

Abnormal findings in

- Activity intolerance related to oxygen supply and demand imbalance
- Bradycardia
- CAD
- Chest pain related to ischemia or inflammation
- Decreased cardiac output
- Dysrhythmias
- Hypertension
- PAD

- ST segment depression of 1 mm (considered a positive test), indicating myocardial ischemia
- Tachycardia

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

The following factors may impair interpretation of examination results because they create an artificial state that makes it difficult to determine true physiological function:

- Anxiety or panic attack.
- Drugs such as beta blockers, cardiac glycosides, calcium channel blockers, coronary vasodilators, and barbiturates.
- High food intake or smoking before testing.
- Hypertension, hypoxia, left bundle branch block, and ventricular hypertrophy.
- Improper electrode placement.
- Potassium or calcium imbalance.
- Viagra should not be taken in combination with nitroglycerin or other nitrates 24 hr prior to the procedure because it may result in a dangerously low blood pressure.
- Wolff-Parkinson-White syndrome (anomalous atrioventricular excitation).

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the heart's ability to respond to an increasing workload.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially

allergies or sensitivities to latex or medications used to pharmacologically exercise the patient's heart.

- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Inquire if the patient has had any chest pain within the past 48 hr or has a history of anginal attacks; if either of these has occurred, inform the health-care provider (HCP) immediately because the stress test may be too risky and should be rescheduled in 4 to 6 wk.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some discomfort may be experienced during the stimulated portion of the test. Inform the patient that the procedure is performed in a special department by an HCP specializing in this procedure and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Record a baseline 12-lead ECG and vital signs.
- ▶ Instruct the patient to wear comfortable shoes and clothing for the exercise.
- ▶ Instruct the patient to fast, restrict fluids, and avoid tobacco products for 4–6 hr prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Myocardial infarction (MI)

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary and tobacco restrictions for at least 4 to 6 hr prior to the procedure.

- ▶ An IV access may be established for emergency use.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown provided.
- ▶ Place electrodes in appropriate positions on the patient and connect a blood pressure cuff to a monitoring device. If the patient's oxygen consumption is to be continuously monitored, connect the patient to a machine via a mouthpiece or to a pulse oximeter via a finger lead.
- ▶ Instruct the patient to walk on a treadmill (most commonly used) and use the handrails to maintain balance or to peddle a bicycle. As stress is increased, inform the patient to report any symptoms, such as chest or leg pain, dyspnea, or fatigue.
- ▶ Turn the treadmill on at a slow speed, and increase in speed and elevation to raise the patient's heart rate. Increase the stress until the patient's predicted target heart rate is reached.
- ▶ Instruct the patient to report symptoms such as dizziness, sweating, breathlessness, or nausea, which can be normal, as speed increases. The test is terminated if pain or fatigue is severe; maximum heart rate under stress is attained; signs of ischemia are present; maximum effort has been achieved; or dyspnea, hypertension (systolic blood pressure greater than 200 mm Hg, diastolic blood pressure greater than 110 mm Hg, or both), tachycardia (greater than 200 beats/min minus person's age), new dysrhythmias, chest pain that begins or worsens, faintness, extreme dizziness, or confusion develops.
- ▶ After the exercise period, allow a 3- to 15-min rest period with the patient in a sitting position. During this period, the ECG, blood pressure, and heart rate monitoring is continued.

- ▶ Remove the electrodes and cleanse the skin of any remaining gel or ECG electrode adhesive.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual activity, as directed by the HCP.
- ▶ Instruct the patient to contact the HCP to report any anginal pain or other discomforts experienced after the test.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation of moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approach to

Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

- Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25 % of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org), the NHLBI (www.nhlbi.nih.gov), or the Legs for Life (www.legsforlife.org). Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
 - ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, atrial natriuretic peptide, BNP, blood gases, blood pool imaging, calcium,

chest x-ray, cholesterol (total, HDL, LDL), CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, echocardiography, echocardiography transesophageal, electrocardiogram, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isos, lipoprotein electrophoresis,

lung perfusion scan, magnesium, MRI chest, MI infarct scan, myocardial perfusion heart scan, myoglobin, PET heart, potassium, pulse oximetry, sodium, triglycerides, and troponin.

Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Fecal Analysis

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess for the presence of blood in the stool toward diagnosing gastrointestinal bleeding, cancer, inflammation, and infection.

SPECIMEN: Stool.

NORMAL FINDINGS: (Method: Macroscopic examination, for appearance and color; microscopic examination, for cell count and presence of meat fibers; leukocyte esterase, for leukocytes; Clinitest [Bayer Corporation, Pittsburgh, Pennsylvania] for reducing substances; guaiac, for occult blood; x-ray paper, for trypsin.)

Characteristic	Normal Result
Appearance	Solid and formed
Color	Brown
Epithelial cells	Few to moderate
Fecal fat	See "Fecal Fat" monograph
Leukocytes (white blood cells)	Negative
Meat fibers	Negative
Occult blood	Negative
Reducing substances	Negative
Trypsin	2+ to 4+

DESCRIPTION: Feces consist mainly of cellulose and other undigested foodstuffs, bacteria, and water. Other substances normally found in feces include epithelial cells shed from the gastrointestinal (GI) tract, small amounts of fats, bile pigments in the form of urobilinogen, GI and pancreatic secretions, electrolytes, and trypsin. Trypsin is a proteolytic enzyme produced in the pancreas. The average adult excretes 100 to 300 g of fecal material per day, the residue of approximately 10 L of liquid material that enters the GI tract each day. The laboratory analysis of feces includes macroscopic examination (volume, odor, shape, color, consistency, presence of mucus), microscopic examination (leukocytes, epithelial cells, meat fibers), and chemical tests

for specific substances (occult blood, trypsin, estimation of carbohydrate). Detection of occult blood is the most common test performed on stool. The prevalence of colorectal adenoma is greater than 30% in people aged 60 and older. Progression from adenoma to carcinoma occurs over a period of 5 to 12 yr; from carcinoma to metastatic disease in 2 to 3 yr.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in diagnosing disorders associated with GI bleeding or drug therapy that leads to bleeding
- Assist in the diagnosis of pseudomembranous enterocolitis after use of broad-spectrum antibiotic therapy

- Assist in the diagnosis of suspected inflammatory bowel disorder
 - Detect altered protein digestion
 - Detect intestinal parasitic infestation, as indicated by diarrhea of unknown cause
 - Investigate diarrhea of unknown cause
 - Monitor effectiveness of therapy for intestinal malabsorption or pancreatic insufficiency
 - Screen for cystic fibrosis
- Leukocytes: *inflammation of the intestines related to bacterial infections of the intestinal wall, salmonellosis, shigellosis, or ulcerative colitis*
 - Meat fibers: *Altered protein digestion, pancreatitis*
 - Occult blood: *Anal fissure, diverticular disease, esophageal varices, esophagitis, gastritis, hemorrhoids, infectious diarrhea, inflammatory bowel disease, Mallory-Weiss tears, polyps, tumors, ulcers*
 - pH: *related to inflammation in the intestine from colitis, cancer, or antibiotic use*

POTENTIAL DIAGNOSIS

Unusual Appearance

- Bloody: *Excessive intestinal wall irritation or malignancy*
- Bulky or frothy: *Malabsorption*
- Mucous: *Inflammation of intestinal walls*
- Slender or ribbonlike: *Obstruction*

Unusual Color

- Black: *Bismuth (antacid) or charcoal ingestion, iron therapy, upper GI bleeding*
- Grayish white: *Barium ingestion, bile duct obstruction*
- Green: *Antibiotics, biliverdin, green vegetables*
- Red: *Beets and food coloring, lower GI bleed, phenazopyridine hydrochloride compounds, rifampin*
- Yellow: *Rhubarb*

Increased

- Blood *related to bleeding in the digestive tract*
- Carbohydrates/reducing substances: *Malabsorption syndromes, inability to digest some sugars*
- Epithelial cells: *Inflammatory bowel disorders*
- Fat *pancreatitis, sprue (celiac disease), cystic fibrosis related to malabsorption*

Decreased

- Carbohydrates *sprue, cystic fibrosis, malnutrition, medications such as colchicine (gout) or birth control pills*
- Leukocytes: *Amebic colitis, cholera, disorders resulting from toxins, parasites, viral diarrhea*
- pH: *related to poor absorption of carbohydrate or fat*
- Trypsin: *Cystic fibrosis, malabsorption syndromes, pancreatic deficiency*

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that can cause positive results for occult blood include acetylsalicylic acid, anticoagulants, colchicine, corticosteroids, iron preparations, and phenylbutazone.
- Ingestion of a diet high in red meat, certain vegetables, and bananas can cause false-positive results for occult blood.
- Large doses of vitamin C can cause false-negative occult blood.
- Constipated stools may not indicate any trypsin activity owing to extended exposure to intestinal bacteria.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Bleeding (<i>Related to bowel inflammation; irritation; infection; chronic disease</i>)	Altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; capillary refill greater than 3 sec; cool extremities	Monitor and trend HGB/HCT, platelet count; increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; assess diet for iron-rich foods, and foods with vitamin K; discuss the importance of reporting black or tarry stools that are indicative of gastrointestinal bleeding; assess for cultural or religious barriers to blood transfusion
Pain (<i>Related to infection; inflammation; contractions of diseased bowel</i>)	Colicky intermittent abdominal pain; bloating; cramping; distention; self-report of pain; abdominal tenderness; hyperactive bowel sounds; increased pain and cramping with eating	Assess the degree in cramping, colicky abdominal pain, and bloating with eating; auscultate bowel sounds; evaluate tolerance of dairy products in the diet; identify successful pain management strategies that have been used in the past; administer prescribed medications (sulfasalazine, corticosteroids, immunosuppressants, immunomodulators, anticholinergics, anti-diarrheal); recommend diversional activities as a pain management modality; collaborate to make necessary dietary alterations that will decrease bowel irritation
Nutrition (<i>Related to inadequate absorption;</i>	Decreased weight; poor wound healing; pedal pedal edema;	Monitor and trend serum calcium, potassium, vitamin K and B ₁₂ , zinc, and folic acid;

Problem	Signs & Symptoms	Interventions
decreased caloric intake; nausea; diarrhea with nitrogen loss)	decreased calcium, potassium, vitamins, zinc, folic acid; skin lesions; muscle wasting	take an accurate actual weight daily (not verbally reported or estimated); assess for skin lesions; assess current dietary habits and caloric intake; arrange dietary consult and collaboration to develop an appropriate diet; administer ordered vitamin supplements; discuss the possibility of using total parenteral nutrition if oral intake is not sufficient
Fluid volume (Related to nausea; vomiting; diarrhea)	Hypotension; decreased cardiac output; decreased urinary output; dry skin/mucous membranes; poor skin turgor; sunken eyeballs; increased urine specific gravity; hemoconcentration	Assess current hydration status, skin turgor, check for the presence of dry mucous membranes, assess for decreased urine output, dark urine, hypotension; check stools for occult blood; assess for tarry or black stools (indicative of bleeding); administer IV fluids, blood and blood products as ordered; encourage oral intake

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
 - ▶ **Patient Teaching:** Inform the patient this test can assist in the diagnosis of intestinal disorders.
 - ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
 - ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
 - ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient of the procedure for collecting a stool sample, including the importance of good hand-washing techniques. The patient should place the sample in a tightly covered container. Instruct the patient not to contaminate the specimen with urine, water, or toilet tissue. Address concerns about pain and explain that there should be no discomfort during the procedure.
 - ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
 - ▶ Instruct the patient not to use laxatives, enemas, or suppositories for 3 days before the test.

▶ Instruct the patient to follow a normal diet. If the test is being performed to identify blood, instruct the patient to follow a special diet that includes small amounts of chicken, turkey, and tuna (no red meats), raw and cooked vegetables and fruits, and bran cereal for several days before the test. Foods to avoid with the special diet include beets, turnips, cauliflower, broccoli, bananas, parsnips, and cantaloupe, because these foods can interfere with the occult blood test.

Potential Complications: N/A

- F**
- ▶ Ensure that the patient has complied with medication restrictions; assure laxatives, enemas, or suppositories have been restricted for at least 3 days prior to the procedure.
 - ▶ Instruct the patient to cooperate fully and to follow directions.
 - ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and suspected cause of enteritis; note any current or recent antibiotic therapy.
 - ▶ Collect a stool specimen in a half-pint waterproof container with a tight-fitting lid; if the patient is not ambulatory, collect it in a clean, dry bedpan. Use a tongue blade to transfer the specimen to the container, and include any mucoid and bloody portions. Collect specimen from the first, middle, and last portion of the stool. The specimen should be refrigerated if it will not be transported to the laboratory within 4 hr after collection.
 - ▶ To collect specimen by rectal swab, insert the swab past the anal sphincter, rotate gently, and withdraw. Place the swab in the appropriate container.
 - ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available

to the requesting health-care provider (HCP), who will discuss the results with the patient.

- ▶ The American Cancer Society recommends regular screening for colon cancer, beginning at age 50 yr for individuals without identified risk factors. Their recommendations for frequency of screening: annual for occult blood testing (fecal occult blood testing [FOBT] and fecal immunochemical testing [FIT]); every 5 yr for flexible sigmoidoscopy, double contrast barium enema, and CT colonography; and every 10 yr for colonoscopy. There are both advantages and disadvantages to the screening tests that are available today. Methods to use DNA testing of stool are being investigated and await FDA approval. The DNA test is designed to identify abnormal changes in DNA from the cells in the lining of the colon that are normally shed and excreted in stool. The DNA tests under development use multiple markers to identify colon cancers that demonstrate different, abnormal DNA changes. Unlike some of the current screening methods, the DNA tests would be able to detect precancerous polyps. The most current guidelines for colon cancer screening of the general population as well as of individuals with increased risk are available from the American Cancer Society (www.cancer.org), U.S. Preventive Services Task Force (www.uspreventiveservicestaskforce.org), and the American College of Gastroenterology (www.gi.org). Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Recognize anxiety related to test results.
- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.

- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Note that decisions regarding the need for and frequency of occult blood testing, colonoscopy, or other cancer screening procedures should be made after consultation

Expected Patient Outcomes:

Knowledge

- ▶ States the importance of notifying the HCP of black or tarry stools
- ▶ States understanding that untreated disease could result in colon cancer

Skills

- ▶ Demonstrates proficiency in the self-administration of ordered vitamin supplements

- ▶ Demonstrates the ability to select a diet that will support bowel health and decrease gastric irritation

Attitude

- ▶ Complies with the request to adjust diet to decrease abdominal pain and improve caloric intake
- ▶ Complies with the request to provide a stool specimen for analysis in a timely manner

RELATED MONOGRAPHS:

- ▶ Related tests include α_1 -antitrypsin/phenotyping, barium enema, biopsy intestine, capsule endoscopy, CEA and cancer antigens, chloride sweat, colonoscopy, CT colonoscopy, culture stool, D-xylose tolerance, fecal fat, gliadin antibody, lactose tolerance test, ova and parasites, and proctosigmoidoscopy.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Fecal Fat

SYNONYM/ACRONYM: Stool fat, fecal fat stain.

COMMON USE: To assess for the presence of fat in the stool toward diagnosing malabsorption disorders such as Crohn's disease and cystic fibrosis.

SPECIMEN: Stool (80 mL) aliquot from an unpreserved and homogenized 24- to 72-hr timed collection. Random specimens may also be submitted.

NORMAL FINDINGS: (Method: Stain with Sudan black or oil red O. Treatment with ethanol identifies neutral fats; treatment with acetic acid identifies fatty acids.)

Neutral fat	Random, Semiquantitative
Fatty acids	Less than 60 fat globules/hpf*
	Less than 100 fat globules/hpf
	72-hr, Quantitative
Age (normal diet)	
Infant (breast milk)	Less than 1 g/24 hr
0–6 yr	Less than 2 g/24 hr
Adult	2–7 g/24 hr; less than 20% of total solids
Adult (fat-free diet)	Less than 4 g/24 hr

*hpf = high-power field.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Abetalipoprotein deficiency (*related to lack of transport proteins for absorption*)
- Addison's disease (*related to impaired transport*)
- Amyloidosis (*increased rate of excretion related to malabsorption*)
- Bile salt deficiency (*related to lack of bile salts required for proper fat digestion*)
- Carcinoid syndrome (*increased rate of excretion related to malabsorption*)
- Celiac disease (*increased rate of excretion related to malabsorption*)
- Crohn's disease (*increased rate of excretion related to malabsorption*)
- Cystic fibrosis (*related to insufficient digestive enzymes*)
- Diabetes (*abnormal motility related to primary condition*)
- Enteritis (*increased rate of excretion related to malabsorption*)
- Malnutrition (*related to detrimental effects on organs and systems*)

responsible for digestion, transport, and absorption)

- Multiple sclerosis (*abnormal motility related to primary condition*)
- Pancreatic insufficiency or obstruction (*related to insufficient digestive enzymes*)
- Peptic ulcer disease (*related to improper digestion due to low pH*)
- Pernicious anemia (*related to bacterial overgrowth that decreases overall absorption and results in vitamin B₁₂ deficiency*)
- Progressive systemic sclerosis (*abnormal motility related to primary condition*)
- Thyrotoxicosis (*abnormal motility related to primary condition*)
- Tropical sprue (*increased rate of excretion related to malabsorption*)
- Viral hepatitis (*related to insufficient production of digestive enzymes and bile*)
- Whipple's disease (*increased rate of excretion related to malabsorption*)
- Zollinger-Ellison syndrome (*related to improper digestion due to low pH*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Ferritin

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing and monitoring various forms of anemia related to ferritin levels such as iron-deficiency anemia, anemia of malnourishment related to alcoholism, hemolytic anemia, chronic anemia of inflammation, and anemia related to long-term kidney dialysis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 1)
Newborn	25–200 ng/mL	25–200 mcg/L
1 mo	200–600 ng/mL	200–600 mcg/L
2–5 mo	50–200 ng/mL	50–200 mcg/L
6 mo–15 yr	7–140 ng/mL	7–140 mcg/L
Adult		
Males	20–250 ng/mL	20–250 mcg/L
Females (18–39 yr)	10–120 ng/mL	10–120 mcg/L
Females (40 yr and older)	12–263 ng/mL	12–263 mcg/L

DESCRIPTION: Ferritin, a protein manufactured in the liver, spleen, and bone marrow, consists of a protein shell, apoferritin, and an iron core. The amount of ferritin in the circulation is usually proportional to the amount of stored iron (ferritin and hemosiderin) in body tissues. Levels vary according to age and gender, but they are not affected by exogenous iron intake or subject to diurnal variations. Compared to iron and total iron-binding capacity, ferritin is a more sensitive and specific test for diagnosing iron-deficiency anemia. Iron-deficiency anemia in adults is indicated at ferritin levels less than 10 ng/mL; hemochromatosis or hemosiderosis is indicated at levels greater than 400 ng/mL.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of iron-deficiency anemia
- Assist in the differential diagnosis of microcytic, hypochromic anemias
- Monitor hematological responses during pregnancy, when serum iron is usually decreased and ferritin may be decreased
- Support diagnosis of hemochromatosis or other disorders of iron metabolism and storage

POTENTIAL DIAGNOSIS

Increased in

- Alcoholism (*active abuse, as evidenced by release of ferritin into the circulation from damaged hepatocytes and red blood cells [RBCs]*)
- Breast cancer (*acute, related to release of ferritin as an acute-phase reactant protein; chronic, pathophysiology is uncertain*)
- Hemochromatosis (*related to increased iron deposits in the liver, which stimulate ferritin production*)
- Hemolytic anemia (*related to increased iron levels from hemolyzed RBCs, which stimulate ferritin production*)
- Hemosiderosis (*related to increased iron levels, which stimulate ferritin production*)
- Hepatocellular disease (*acute, related to release of ferritin as an acute-phase reactant protein; chronic, related to release of ferritin into the circulation from damaged hepatocytes*)
- Hodgkin's disease (*acute, related to release of ferritin as an acute-phase reactant protein; chronic, pathophysiology is uncertain*)
- Hyperthyroidism (*possibly related to the stimulating effect of thyroid-stimulating hormone on ferritin production*)

- Infection (*acute, related to release of ferritin as an acute-phase reactant protein; chronic, pathophysiology is uncertain*)
- Inflammatory diseases (*related to release of ferritin as an acute-phase reactant protein*)
- Leukemias (*acute, related to release of ferritin as an acute-phase reactant protein; chronic, pathophysiology is uncertain*)
- Oral or parenteral administration of iron (*evidenced by an increased circulating iron level, which stimulates ferritin production*)
- Thalassemia (*related to increased iron levels from hemolyzed RBCs, which stimulate ferritin production*)

Decreased in

Conditions that decrease iron stores result in corresponding low levels of ferritin.

- Hemodialysis
- Iron-deficiency anemia

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase ferritin levels include ethanol, ferric polymaltose, iron, and oral contraceptives.
- Drugs that may decrease ferritin levels include erythropoietin and methimazole.
- Recent transfusion can elevate serum ferritin.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in the diagnosis of anemia.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Nutritional therapy may be indicated for patients with decreased ferritin values because this may indicate corresponding iron deficiency. Instruct these patients in the dietary inclusion of iron-rich foods and in the administration of iron supplements, including side effects, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be

performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, biopsy liver, complement, CBC, CBC hematocrit, CBC hemoglobin, CBC platelet count, CBC RBC count, CBC RBC indices, CBC RBC morphology and inclusions, CBC WBC count and differential, Coomb's antiglobulin direct and indirect, erythropoietin, FEP, G6PD, Ham's test, Hgb electrophoresis, hemosiderin, iron/TIBC, osmotic fragility, PK, sickle cell screen, and transferrin.
- ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Fetal Fibronectin

SYNONYM/ACRONYM: fFN.

COMMON USE: To assist in assessing for premature labor.

SPECIMEN: Swab of vaginal secretions.

NORMAL FINDINGS: (Method: Immunoassay) Negative.

DESCRIPTION: Fibronectin is a protein found in fetal connective tissue, amniotic fluid, and the placenta of pregnant women. Placental fetal fibronectin (fFN) is concentrated in the area where the placenta and its membranes are in contact with the uterine wall. It is first secreted early in pregnancy and is believed to help implantation of the fertilized egg to the uterus. Fibronectin is not detectable again until just before delivery, at approximately 37 wk.

If it is detected in vaginal secretions at 22 to 34 wk of gestation, delivery may happen prematurely. The test is a useful marker for impending membrane rupture within 7 to 14 days if the level rises to greater than 0.05 mcg/mL.

This procedure is contraindicated for: N/A

INDICATIONS

Investigate signs of premature labor

POTENTIAL DIAGNOSIS

Positive findings in

- Premature labor (*possibly initiated by mechanical or infectious processes, the membranes pull away from the uterine wall and amniotic fluid containing fFN leaks into endocervical fluid*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

If signs and symptoms persist in light of negative test results, repeat testing may be necessary.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assess for risk of preterm delivery.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that the patient knows the symptoms of premature labor, which include uterine contractions (with or without pain) lasting 20 sec or longer or increasing in frequency, menstrual-like cramping (intermittent or continuous), pelvic pressure, lower back pain that does not dissipate with a change in position, persistent diarrhea, intestinal cramps, changes in vaginal discharge, or a feeling that something is wrong.
- ▶ The health-care provider (HCP) should be informed if contractions occur more frequently than four times per hour.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and

neutraceuticals (see Appendix H online at DavisPlus).

- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min and will be performed by an HCP specializing in this branch of medicine. Address concerns about pain related to the procedure. Explain to the patient that there should be minimal to no discomfort during the procedure.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Position the patient on the gynecological examination table with the feet up in stirrups. Drape the patient's legs to provide privacy and to reduce chilling. Collect a small amount of vaginal secretion using a special swab from a fetal fibronectin kit.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications

of the test results, as appropriate. Educate the patient regarding access to counseling services.

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain the possible causes and increased risks associated with premature labor and delivery. Reinforce education on signs and symptoms of labor, as appropriate. Inform the patient that hospitalization or more frequent prenatal checks may be ordered. Other therapies may also be administered, such as antibiotics, corticosteroids, and IV tocolytics. Instruct the patient in the importance of completing the entire course of antibiotic therapy, if ordered, even if no symptoms are present. Answer any questions or

address any concerns voiced by the patient or family.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include amniotic fluid analysis (nitrazine and fern test), biopsy chorionic villus, chromosome analysis, estradiol, α_1 -fetoprotein, HCG, LS ratio, progesterone, and US biophysical profile obstetric.
- Refer to the Reproductive System table at the back of the book for related tests by body system.

α_1 -Fetoprotein

SYNONYM/ACRONYM: AFP.

COMMON USE: To assist in the evaluation of fetal health related to neural tube defects and some forms of liver cancer.

SPECIMEN: Serum (1 mL for tumor marker in men and nonpregnant women; 3 mL for maternal triple- or quad-marker testing), collected in a gold-, red-, or red/gray-top tube. For maternal triple- or quad-marker testing, include human chorionic gonadotropin and free estriol measurement.

NORMAL FINDINGS: (Method: Immunochemiluminometric assay)

α_1 -Fetoprotein as a Tumor Marker: Males, Females, and Children

	Males (Conventional Units)	SI Units (Conventional Units × 1)	Females (Conventional Units)	SI Units (Conventional Units × 1)
Less than 1 mo	0.5–16,387 ng/mL	0.5–16,387 mcg/L	0.5–18,964 ng/mL	0.5–18,964 mcg/L
1–11 mo	0.5–28.3 ng/mL	0.5–28.3 mcg/L	0.5–77 ng/mL	0.5–77 mcg/L
1–3 yr	0.5–7.9 ng/mL	0.5–7.9 mcg/L	0.5–11.1 ng/mL	0.5–11.1 mcg/L
4 yr and older	Less than 6.1 ng/mL	Less than 6.1 mcg/L	Less than 6.1 ng/mL	Less than 6.1 mcg/L

Values may be higher for premature newborns.

α_1 -Fetoprotein (AFP) in Maternal Serum for Triple or Quad Marker

	White AFP (Median)	Black AFP (Median)	Hispanic AFP (Median)	Asian AFP (Median)
Low risk	Less than 2 MoM	Less than 2 MoM	Less than 2 MoM	Less than 2 MoM

MoM = multiples of the median. Serum values vary with maternal race, weight, weeks of gestation, diabetic status, and number of fetuses, and variations exist between test methods. Serial testing should be determined using the same test method.

Gestational Age (wk)	HCG (Conventional Units)	SI Units (Conventional Units \times 1)
2 wk	5–100 milli-international units/mL	5–100 international units/L
3 wk	200–3,000 milli-international units/mL	200–3,000 international units/L
4 wk	10,000–80,000 milli-international units/mL	10,000–80,000 international units/L
5–12 wk	90,000–500,000 milli-international units/mL	90,000–500,000 international units/L
13–24 wk	5,000–80,000 milli-international units/mL	5,000–80,000 international units/L
26–28 wk	3,000–15,000 milli-international units/mL	3,000–15,000 international units/L
<i>Pregnancy-associated plasma protein A (PAPP-A)</i>		
8 wk	90–7,000 milli-international units/L	
9 wk	0–5,800 milli-international units/L	
10 wk	140–7,000 milli-international units/L	
11 wk	575–7,250 milli-international units/L	
12 wk	900–9,000 milli-international units/L	
13 wk	550–11,500 milli-international units/L	
14 wk	2,200–39,500 milli-international units/L	
	Unconjugated Estriol (E3) (Conventional Units)	SI Units (Conventional Units \times 3.467)
30 wk	3.5–19 ng/mL	12.1–65.9 nmol/L
34 wk	5.3–18.3 ng/mL	18.4–63.5 nmol/L
35 wk	5.2–26.4 ng/mL	18–91.6 nmol/L
36 wk	8.2–28.1 ng/mL	28.4–97.5 nmol/L
37 wk	8–30.1 ng/mL	27.8–104.4 nmol/L
38 wk	8.6–38 ng/mL	29.8–131.9 nmol/L
39 wk	7.2–34.3 ng/mL	25–119 nmol/L
40 wk	9.6–28.9 ng/mL	33.3–100.3 nmol/L

Results vary widely among laboratories and methods.

HCG = human chorionic gonadotropin.

DESCRIPTION: Maternal blood screening for birth defects is optimally performed between 16 and 18 wk but may be done as early as 15 wk or as late as 22.9 wk. A number of serum and amniotic fluid markers can be used in collaboration to screen for Down syndrome, neural tube defects, and trisomy 18. These markers include α_1 -fetoprotein (AFP), human chorionic gonadotropin (HCG), unconjugated estriol, dimeric inhibin-A (DIA), and pregnancy-associated plasma protein A (PAPP-A). Ultrasound (nuchal translucency [NT] ultrasound measurements of the fluid-filled space in the back of the fetus's neck, larger-than-normal NT measurements are found in Down syndrome), maternal age, race, weight, diabetic status, and number of fetuses are also factors used to calculate risk. The algorithm used to calculate risk depends on whether gestational age is based on ultrasound findings or date of last menstrual period. Diagnostic tests that include AFP, acetylcholinesterase, chromosome analysis, and fetal hemoglobin testing performed on amniotic fluid are discussed in the monographs titles "Amniotic Fluid Analysis" and "Biopsy, Chorionic Villus."

AFP is a glycoprotein produced in the fetal liver, gastrointestinal tract, and yolk sac. AFP is the major serum protein produced for 10 wk in early fetal life. (See "Amniotic Fluid Analysis" monograph for measurement of AFP levels in amniotic fluid.) After 10 wk of gestation, levels of fetal AFP can be detected in maternal blood, with peak levels occurring at 16 to 18 wk. Elevated maternal levels of AFP on two tests taken 1 wk apart suggest further investigation into fetal well-being by ultrasound or amniocentesis. HCG, a hormone secreted by the

placenta, stimulates secretion of progesterone by the corpus luteum. (The use of HCG as a triple marker is also discussed in the monograph titled "Human Chorionic Gonadotropin.") During intrauterine development, the normal fetus and placenta produce estriol, a portion of which passes into maternal circulation.

Decreased estriol levels are an independent indicator of neural tube defects. Dimeric inhibin-A (DIA) is the fourth biochemical marker used in prenatal quad screening. It is a glycoprotein secreted by the placenta. Maternal blood levels of DIA normally remain fairly stable during the 15th to 18th weeks of pregnancy. Blood levels are twice as high in the second trimester of pregnancies affected by Down syndrome. The incidence of Down syndrome is 1 in 750 live births. The triple screen detection rate for Down syndrome is 67%. The Down syndrome detection rate increases to 76% and maintains a false-positive rate of 5% when DIA is included. The incidence of neural tube defects is 1 in 1,300 pregnancies; anencephaly is almost always fatal at, or within a very short time after, birth. The incidence of trisomy 18 is 1 in 4,100 live births; most die within the first year after birth.

The presence of AFP in excessive amounts is abnormal in adults and children. AFP measurements are used as a tumor marker to assist in the diagnosis of cancer.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of primary hepatocellular carcinoma or

metastatic lesions involving the liver, as indicated by highly elevated levels (30% to 50% of Americans with liver cancer do not have elevated AFP levels)

- Investigate suspected hepatitis or cirrhosis, indicated by slightly to moderately elevated levels
- Monitor response to treatment for hepatic carcinoma, with successful treatment indicated by an immediate decrease in levels
- Monitor for recurrence of hepatic carcinoma, with elevated levels occurring 1 to 6 mo before the patient becomes symptomatic
- Investigate suspected intrauterine fetal death, as indicated by elevated levels
- Routine prenatal screening at 15 to 16 wk of pregnancy for fetal neural tube defects and other disorders, as indicated by elevated levels in maternal serum and amniotic fluid
- Support diagnosis of embryonal gonadal teratoblastoma, hepatoblastoma, and testicular or ovarian carcinomas

POTENTIAL DIAGNOSIS

Maternal serum AFP test results report actual values and multiples of the median (MoM) by gestational age (in weeks). MoM are calculated by dividing the patient's AFP by the midpoint (or median) of values expected for a large population of unaffected women at the same gestational age in weeks. MoM should be corrected for maternal weight. The MoM should also be corrected for maternal insulin requirement (achieved by dividing MoM by 1.1 for diabetic African American patients and by 0.8 for diabetic patients of other races) and multiple fetuses (multiply by 2.13 for twins). Some laboratories also provide additional statistical information regarding Down syndrome risk.

Increased in

- Pregnant women:
 - Congenital nephrosis (*related to defective renal reabsorption*)
 - Fetal abdominal wall defects (*related to release of AFP from open body wall defect*)
 - Fetal distress
 - Fetal neural tube defects (e.g., anencephaly, spina bifida, myelomeningocele) (*related to release of AFP from open body wall defect*)
 - Low birth weight (*related to inaccurate estimation of gestational age*)
 - Multiple pregnancy (*related to larger quantities from multiple fetuses*)
 - Polycystic kidneys (*related to defective renal reabsorption*)
 - Underestimation of gestational age (*related to the expectation of a lower value based on incorrect prediction of gestational age, i.e., AFP increases with age; therefore, if the age is believed to be less than it is actually, the expectation of the corresponding AFP value will be lower than it is actually, and the result appears to be elevated*)
- Men, nonpregnant women, and children (the cancer cells contain undifferentiated hepatocytes that produce glycoproteins of fetal origin):
 - Cirrhosis
 - Hepatic carcinoma
 - Hepatitis
 - Metastatic lesions involving the liver

Decreased in

- Pregnant women:
 - Down syndrome (trisomy 21)
 - Edwards' syndrome (trisomy 18)
 - Fetal demise (undetected over a lengthy period of time) (*related to cessation of AFP production*)
 - Hydatidiform moles (*partial mole may secrete some AFP*)
 - Overestimation of gestational age (*related to the expectation of a higher value based on incorrect prediction of gestational age; i.e., AFP increases with age; therefore, if the age is believed to be greater than it actually is, the expectation of the corresponding AFP value will be greater than it actually is, and the result appears to be decreased*)

Pseudopregnancy (*there is no fetus to produce AFP*)

Spontaneous abortion (*there is no fetus to produce AFP*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may decrease AFP levels in pregnant women include acetaminophen, acetylsalicylic acid, and phenacetin.
- Multiple fetuses can cause increased levels.
- Gestational age must be between 15 and 22 wk for initial and follow-up testing. The most common cause of an abnormal MoM is inaccurate estimation of gestational age (defined as weeks from the first day of the last menstrual period).
- Maternal AFP levels vary by race.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fear (<i>Related to prognosis secondary to diagnosis [cancer]; disabled child; ability to function in caregiver role; risk of death (cancer); loss of control; ineffective coping; unfamiliar therapeutic regime; unknown</i>)	Expression of fear; preoccupation with fear; increased tension; increased blood pressure; increased heart rate; vomiting; diarrhea; nausea; fatigue; weakness; insomnia; shortness of breath; increased respiratory rate; withdrawal; panic attacks	Provide specific education related to disease process (neural tube defect, liver disease); provide specific information related to treatment based on diagnosis or defect; access social services; ensure education is culturally appropriate; assist the patient and family to recognize effective coping strategies; assist the patient and family to acknowledge their fear; provide a safe environment to discuss fear; explore cultural influences that may enhance fear; utilize therapeutic touch as appropriate to decrease fear
Fatigue (<i>Related to hepatic disease process; malnutrition; anemia; chemotherapy; radiation therapy</i>)	Decreased concentration; increased physical complaints; inability to restore energy with sleep; report of being tired; inability to maintain normal routine	Assess for physical cause of fatigue; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia

(table continues on page 794)

Problem	Signs & Symptoms	Interventions
Confusion; altered sensory perception <i>(Related to an alteration in fluid and electrolytes, hepatic disease and encephalopathy; acute alcohol consumption; hepatic metabolic insufficiency)</i>	Disorganized thinking, restless, irritable, altered concentration and attention span, changeable mental function over the day, hallucinations; altered attention span; unable to follow directions; disoriented to person, place, time, and purpose; inappropriate affect	Treat the medical condition; correlate confusion with the need to reverse altered electrolytes; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or restraints; consider pharmacological interventions; record accurate intake and output to assess fluid status; monitor blood ammonia level; determine last alcohol use; assess for symptoms of hepatic encephalopathy such as confusion, sleep disturbances, incoherence; protect the patient from physical harm; administer lactulose as prescribed
Spirituality <i>(Related to significant loss; fear of death; debilitation disease process; diagnosed child disability)</i>	Forgiveness; acceptance; anger at spiritual leaders; expressed feelings of hopeless, powerlessness; abandonment; refusals or inability to participate in spiritual activities (prayer); expresses feelings over lack of meaning with life or serenity	Encourage the verbalization of feelings in a safe, nonjudgmental environment; assess the desire for contact from associated spiritual leader; foster a supportive relationship with the patient and family; encourage a display of objects (spiritual, religious) that provide emotional relief; assess for expressions of hope

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating fetal health.
- ▶ Obtain a history of the patient's complaints and known or suspected malignancy. Obtain a list of known allergens,

especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's immune and reproductive systems, gestational age, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.

- ▶ Provide required information to laboratory for triple-marker testing, including maternal birth date, weight, age, race, calculated gestational age, gestational age by ultrasound, gestational date by physical examination, first day of last menstrual period, estimated date of delivery, and whether the patient has insulin-dependent (type 1) diabetes.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ *Consent may be required for this type of testing. As appropriate make sure a written and informed consent has been signed prior to the venipuncture procedure.*

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ The sample may be collected directly from the cord using a syringe and transferred to a red-top tube.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Hyperhomocysteinemia resulting from folate deficiency in pregnant women is believed to increase the risk of neural tube defects. Elevated levels of homocysteine are thought to chemically damage the exposed neural tissue of the developing fetus. As appropriate, instruct pregnant patients to eat foods rich in folate, such as liver, salmon, eggs, asparagus, green leafy vegetables, broccoli, sweet potatoes, beans, and whole wheat.
- ▶ **Social and Cultural Considerations:** In pregnant patients, recognize anxiety related to test results, and encourage the family to seek counseling if concerned with pregnancy termination or to seek genetic counseling if a chromosomal abnormality is determined. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if fetal abnormalities are detected. Educate the patient regarding access to counseling services.
- ▶ In patients with carcinoma, recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Inform the pregnant patient

that an ultrasound may be performed and AFP levels in amniotic fluid may be analyzed if maternal blood levels are elevated in two samples obtained 1 wk apart. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services, as appropriate.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that neural tube defect is a causative factor in birth disabilities

- ▶ States a clear understanding of the plan of care developed to support the health of the disabled child

Skills

- ▶ Designs a plan to support the home care of the disabled child while meeting own basic needs
- ▶ Demonstrates proficiency in administering medication to the disabled child

Attitude

- ▶ Complies with the request to attend a support group for parents of disabled children
- ▶ Complies with the recommendation to abstain from alcohol use as it can exacerbate liver disease

RELATED MONOGRAPHS:

- ▶ Related tests include amniotic fluid analysis and L/S ratio, biopsy chorionic villus, cancer antigens, estradiol, fetal fibronectin, folic acid, hexosaminidase, homocysteine, HCG, L/S ratio, and US biophysical profile obstetric.
- ▶ Refer to the Immune and Reproductive systems tables at the end of the book for related tests by body system.

Fetoscopy

SYNONYM/ACRONYM: Endoscopic fetal surgery, fetal endoscopy.

COMMON USE: To facilitate diagnosis and treatment of the fetus. Evaluate for disorders such as neural tube defects and congenital blood disorders, and assist with fetal karyotyping.

AREA OF APPLICATION: Fetus, uterus.

CONTRAST: N/A.

DESCRIPTION: Fetoscopy is usually performed around the 18th week of pregnancy or later when the fetus is developed sufficiently for diagnosis of potential problems. It is done to evaluate or treat the fetus during pregnancy. Fetoscopy

can be accomplished externally using a stethoscope with an attached headpiece, which is placed on the mother's abdomen to assess the fetal heart tones. Endoscopic fetoscopy is accomplished using an instrument

called a fetoscope, a thin, 1-mm flexible scope, which is placed with the aid of sonography. The fetoscope is inserted into the uterus through a thin incision in the abdominal wall (transabdominally) or through the cervix (transcervically) in earlier stages of pregnancy. Fetal tissue and blood samples can be obtained through the fetoscope. In addition, fetal surgery can be performed for such procedures as the repair of a fetal congenital diaphragmatic hernia, enlarged bladder, and spina bifida.

This procedure is contraindicated for: N/A

INDICATIONS

- Pregnancy

POTENTIAL DIAGNOSIS

Normal findings in

- Absence of birth defects

Abnormal findings in

- Acardiac twin
- Congenital diaphragmatic hernia (CDH)
- Hemophilia
- Neural tube defects
- Spinal bifida

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Activity of fetus.
- Amniotic fluid that is extremely cloudy.
- Inability of patient to remain still during the procedure.
- Obesity or very overweight patient.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in locating and treating fetal abnormalities.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results (i.e., barium procedures, surgery, or biopsy).
- ▶ Record the date of last menstrual period and determine the age of the fetus.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Instruct the patient to remove jewelry and other metallic objects in the area to be examined.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that a local anesthetic will be applied to the abdomen to ease with insertion of the fetoscope. Inform the patient that the procedure is performed in an ultrasound department, by a health-care provider (HCP) specializing in this procedure, with support staff, and takes approximately 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct patient that food and fluid should be withheld for 8 hr prior to the procedure. There are no medication restrictions unless by medical direction.

▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions; ensure that food and fluid has been restricted for at least 8 hr prior to the procedure.
- ▶ Ensure that the patient has removed external metallic objects prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Instruct the patient to lie on her back. The lower abdomen area is cleaned, and a local anesthetic is administered in the area where the incision will be made.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection if samples are to be obtained on aspirated amniotic fluid or fetal material.
- ▶ Conductive gel is applied to the skin, and a Doppler transducer is moved over the skin to locate the position of the fetus.
- ▶ Ask the patient to breathe normally during the examination. If necessary for better fetal visualization, ask the patient to inhale deeply and hold her breath.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available

to the requesting HCP, who will discuss the results with the patient.

- ▶ When the study is completed, remove the gel from the skin.
- ▶ Observe/assess the incision for redness or leakage of fluid or blood.
- ▶ Instruct the patient in the care of the incision and to contact her HCP immediately if she is experiencing chills, fever, dizziness, moderate or severe abdominal cramping, or fluid or blood loss from the vagina or incision.
- ▶ Inform the patient that a follow-up ultrasound will be completed the next day to assess the fetus and placenta.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include amniotic fluid analysis and L/S ratio, biopsy chorionic villus, blood groups and antibodies, chromosome analysis, culture bacterial anal/genital, culture viral, fetal fibronectin, α_1 -fetoprotein, hexosaminidase A and B, human chorionic gonadotropin, KUB, Kleihauer-Betke test, prolactin, MRI abdomen, and ultrasound biophysical profile obstetric.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Fibrinogen

SYNONYM/ACRONYM: Factor I.

COMMON USE: Commonly used to evaluate fibrinolytic activity as well as identify congenital deficiency, disseminated intravascular coagulation (DIC), and severe liver disease.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Photo-optical clot detection)

Age	Conventional Units	SI Units (Conventional Units × 0.0294)
Newborn	200–500 mg/dL	5.9–14.7 micromol/L
Adult	200–400 mg/dL	5.9–11.8 micromol/L

Values are higher in older adults.

DESCRIPTION: Fibrinogen (factor I) is an acute phase reactant protein synthesized in the liver. It is an essential component in the process of hemostasis or clot formation. In the common final pathway of the coagulation process, thrombin converts fibrinogen to fibrin, which then become crosslinked fibrin monomers, and ultimately a stable fibrin clot. The use of fibrinogen levels is not limited to coagulation studies. The role of fibrinogen in the inflammatory response has also established an association between elevated levels and vascular diseases like coronary heart disease, myocardial infarction, stroke, and peripheral artery disease.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of suspected disseminated intravascular

coagulation (DIC), as indicated by decreased fibrinogen levels

- Evaluate congenital or acquired dysfibrinogenemias
- Monitor hemostasis in disorders associated with low fibrinogen levels or elevated levels that can predispose patients to excessive thrombosis

POTENTIAL DIAGNOSIS

Increased in

Fibrinogen is an acute-phase reactant protein and will be increased in inflammatory conditions.

- Acute myocardial infarction
- Cancer
- Eclampsia
- Hodgkin's disease
- Inflammation
- Multiple myeloma
- Nephrotic syndrome
- Pregnancy
- Stroke
- Tissue necrosis

Decreased in

- Congenital fibrinogen deficiency (rare) (*related to deficient synthesis*)
- DIC (*related to rapid consumption as fibrinogen is converted to fibrin*)
- Dysfibrinogenemia (*related to an inherited abnormality in fibrinogen synthesis*)
- Liver disease (severe) (*related to decreased synthesis*)
- Primary fibrinolysis (*related to rapid conversion during fibrinolysis; plasmin breaks down fibrinogen and fibrin*)

CRITICAL FINDINGS

- Less than 80 mg/dL (SI: Less than 2.4 micromol/L)

Note and immediately report to the health-care provider (HCP) any critically decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require

completion of a notification form with review by Risk Management.

Signs and symptoms of microvascular thrombosis include cyanosis, ischemic tissue necrosis, hemorrhagic necrosis, tachypnea, dyspnea, pulmonary emboli, venous distention, abdominal pain, and oliguria. Possible interventions include identification and treatment of the underlying cause, support through administration of required blood products (cryoprecipitate or fresh frozen plasma), and administration of heparin. Cryoprecipitate may be a more effective product than fresh frozen plasma in cases where the fibrinogen level is less than 100 mg/dL, the minimum level required for adequate hemostasis, because it delivers a concentrated amount of fibrinogen without as much plasma volume.

INTERFERING FACTORS

- Drugs that may increase fibrinogen levels include acetylsalicylic acid, norethandrolone, oral contraceptives, oxandrolone, and oxymetholone.
- Drugs that may decrease fibrinogen levels include anabolic steroids, asparaginase, bezafibrate, danazol, dextran, fenofibrate, fish oils, gemfibrozil, lovastatin, pentoxifylline, phosphorus, and ticlopidine.
- Considerations for draw times after transfusion include the type of product, the amount of product transfused, and the patient's clinical situation. The circulating half-life of fibrinogen is 3 to 5 days. Generally, specimens are collected 30 to 60 min after a massive transfusion to provide guidance regarding the need for administration of additional units.
- Placement of tourniquet for longer than 60 sec can result in venous stasis and changes in the concentration

of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.

- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.
- Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
- Hematocrit greater than 55% may cause falsely prolonged results because of anticoagulant excess relative to plasma volume.
- Incompletely filled collection tubes, specimens contaminated with heparin, clotted specimens, or unprocessed specimens not delivered to the laboratory within 1 to 2 hr of collection should be rejected.
- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.
- Traumatic venipuncture and excessive agitation of the sample can alter test results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that this lab test can assist in diagnosing diseases associated with clotting disorders.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern or modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Fill tube completely. *Important note:* When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) tubes. Otherwise, when using a standard vacutainer system, the blue-top tube is the first tube collected. When a butterfly is used, due to the added tubing, an extra red-top tube should be collected before the blue-top tube to ensure complete filling of the blue top tube.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to report bruising, petechiae, and bleeding from mucous membranes, hematuria, and occult blood.
- ▶ Inform the patient with a decreased fibrinogen level of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of intramuscular injections.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or

address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, albumin, ALP, AT-III, AST, bilirubin, biopsy bone, biopsy bone marrow, biopsy liver, clot retraction, coagulation factors, CBC platelet count, CT cardiac scoring, CK and isoenzymes, CRP, D-dimer, echocardiography, echocardiography transesophageal, ECG, ESR, exercise stress test, FDP, GGT, Holter monitor, IFE, immunoglobulins, myocardial perfusion heart scan, aPTT, plasminogen, procalcitonin, protein S, and PT/INR.
- ▶ Refer to the Hematopoietic and Hepatobiliary systems tables at the end of the book for related tests by body system.

Fibrinogen Degradation Products

SYNONYM/ACRONYM: Fibrin split products, fibrin breakdown products, FDP, FSP, FBP.

COMMON USE: To evaluate conditions associated with abnormal fibrinolytic and fibrinogenolytic activity such as disseminated intravascular coagulation (DIC), deep vein thrombophlebitis (DVT), and pulmonary embolism (PE).

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Latex agglutination)

Conventional Units

Less than 5 mcg/mL

SI Units (Conventional Units × 1)

Less than 5 mg/dL

DESCRIPTION: This coagulation test evaluates fibrin split products or fibrin/fibrinogen degradation products (FDPs) that interfere with normal coagulation and formation of the hemostatic platelet plug. As thrombin initiates the formation of the fibrin clot, it also activates the fibrinolytic system to limit the size of clot formation and prevent venous occlusion. The D-dimer is specific to secondary fibrinolysis because it detects the disintegration of fibrin rather than fibrinogen. The FDP test detects degradation products of primary fibrinolysis generated by the action of thrombin on fibrinogen as well as degradation products of secondary fibrinolysis by the action of plasmin on fibrin. The two tests together can be useful for differentiation and treatment of suspected cases of fibrinolysis. In the case of primary fibrinolysis, the FDP will be positive while the D-dimer is normal. In DIC, or secondary fibrinolysis, both will be elevated. FDPs are normally cleared rapidly from circulation, however increased circulating levels can interfere with hemostasis by interfering with fibrin polymerization and adhering to platelet cell membranes thereby inhibiting their normal function.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of suspected DIC
- Evaluate response to therapy with fibrinolytic drugs
- Monitor the effects on hemostasis of trauma, extensive surgery, obstetric complications, and disorders such as liver or renal disease

POTENTIAL DIAGNOSIS

Increased in

- DIC (*FDP can be positive in a number of conditions in which the coagulation system has been excessively stimulated as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin*)
- Excessive bleeding (*clot formation related to depletion of platelets and clotting factors will stimulate fibrinolysis and increase circulation of fibrin breakdown products*)
- Liver disease (*related to decreased hepatic clearance*)
- Myocardial infarction (*FDP can be positive in a number of conditions in which the coagulation system has been excessively stimulated as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin*)
- Obstetric complications, such as pre-eclampsia, abruptio placentae, intrauterine fetal death (*excessive stimulation of the coagulation system; microthrombi are formed and plasminogen is released to dissolve the fibrin clots*)
- Post-cardiothoracic surgery period (*FDP can be positive in a number of conditions in which the coagulation system has been excessively stimulated as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin*)
- Pulmonary embolism (*FDP can be positive in a number of conditions in which the coagulation system has been excessively stimulated as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin*)
- Renal disease (*FDP can be positive in a number of conditions in which the coagulation system has been excessively stimulated*)

as a result of tissue injury and fibrin and/or fibrinogen is being degraded by plasmin)

- Renal transplant rejection

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Traumatic venipunctures and excessive agitation of the sample can alter test results.
- Drugs that may increase fibrin degradation product levels include heparin and fibrinolytic drugs such as streptokinase and urokinase.
- The presence of rheumatoid factor may falsely elevate results with some test kits.
- The test should not be ordered on patients receiving heparin therapy.
- Hematocrit greater than 55% may cause falsely prolonged results because of anticoagulant excess relative to plasma volume.
- Incompletely filled collection tubes, specimens contaminated with heparin, clotted specimens, or unprocessed specimens not delivered to the laboratory within 1 to 2 hr of collection should be rejected.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Bleeding (<i>Related to anticoagulant therapy; altered clotting factors; depleted clotting factors</i>)	Altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; capillary refill greater than 3 sec; cool extremities	Increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; administer stool softeners as needed; monitor stool for blood; encourage intake of foods rich in vitamin K; monitor and trend HGB/HCT; assess skin for petechiae, purpura, hematoma; monitor for blood in emesis, or sputum; institute bleeding precautions (prevent unnecessary venipuncture; avoid IM injections; prevent trauma; be gentle with oral care, suctioning; avoid use of a sharp razor); administer prescribed medications (recombinant human activated protien C; epsilon aminocaproic acid)

Problem	Signs & Symptoms	Interventions
Gas exchange <i>(Related to decreased lung tissue perfusion secondary to embolic obstruction; aveolar dead space; increased shunting secondary to alveolar collapse; ventilation perfusion mismatch)</i>	Cyanosis; increased respiratory rate; anxiety; restlessness; confusion; irritability; tachycardia; dyspnea; headache; abnormal ABG; lethargy; somnolence; decreased oxygen saturation (less than 90%); adventitious breath sounds (crackles); areas of decreased lung ventilation; cough, hemoptysis, pleuritic pain in the presence of pulmonary infarct	Monitor and trend ABG results; monitor respiratory rate and effort; monitor and trend pulse oximetry; monitor and trend vital signs; ensure patient does not cross legs while lying or sitting; assess lung sounds frequently; use pulse oximetry to monitor oxygen saturation; collaborate with physician to administer oxygen as needed; elevate the head of the bed 30 degrees; assess for hypoxia symptoms; administer prescribed anticoagulant therapy
Bleeding <i>(Related to altered clotting factors secondary to anticoagulant therapy)</i>	Altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; capillary refill greater than 3 sec; cool extremities	Increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; monitor stool for blood; encourage intake of foods rich in vitamin K; monitor and trend HGB/HCT, INR, PT, PTT; ensure that anticoagulant therapy is accurately administered (IV, PO); assess skin for petechiae, purpura, hematoma; monitor for blood in emesis, or sputum; institute bleeding precautions (prevent unnecessary venipuncture; avoid IM injections; prevent trauma; be gentle with oral care, suctioning; avoid use of a sharp razor)

(table continues on page 806)

Problem	Signs & Symptoms	Interventions
Tissue perfusion (<i>Related to vessel wall injury; blood hypercoagulability</i>)	Femoral, popliteal, or small calf vein tenderness, warmth at involved area, pain with leg palpation, edema; it is possible to be asymptomatic if the DVT is located in a distal vein	Assess for symptoms of DVT; assess for contributing factors (trauma, recent surgery, smoking, varicose veins, age, venous stasis, obesity, pregnancy, oral contraceptive use); monitor diagnostic test results (D-dimer, ultrasound, impedance plethysmography); monitor and trend coagulation studies (PT, INR, PTT); encourage bedrest with leg elevation; administer prescribed anticoagulant therapy; institute bleeding precautions (avoid IM injections, prevent trauma, be gentle with oral care and suctioning, avoid use of a sharp razor); apply moist heat at affected area; apply leg compression devices as prescribed; prepare for potential adjunct therapy (thrombolytic, vena cava filter, thrombectomy)

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing diseases associated with clotting disorders.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic system, any bleeding disorders, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.

- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Fill tube completely. *Important note:* When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) tubes. Otherwise, when using a standard vacutainer system, the blue-top tube is the first tube collected. When a butterfly is used, due to the added tubing, an extra red-top tube should be collected before the blue-top tube to ensure complete filling of the blue top tube.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to report bleeding from skin or mucous membranes, ecchymosis, petechiae, hematuria, and occult blood.
- ▶ Inform the patient with increased levels of fibrin degradation products of the

- importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of IM injections.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach patient that crossing legs increases DVT risk.

Expected Patient Outcomes:

Knowledge

- ▶ States the purpose of anticoagulant therapy as to prevent more clot formation.
- ▶ States understanding that the purpose of heat application to the affected area is to relieve pain and inflammation.

Skills

- ▶ Demonstrates proficiency with deep breathing exercises.
- ▶ Demonstrates proficiency in self-administration of ordered anticoagulant therapy.

Attitude

- ▶ Complies with the request to maintain bedrest until the HCP deems it is safe to resume activity.
- ▶ Complies with the request to refrain from risky activities to prevent injury

RELATED MONOGRAPHS:

- ▶ Related tests include aPTT, ALT, alveolar/arterial gradient, angiography pulmonary, AT-III, AST, bilirubin, biopsy liver, blood pool imaging, BUN, coagulation factors, CT cardiac scoring, creatinine, CBC, CK and isoenzymes, CRP, D-dimer, exercise stress test, FDP, fibrinogen, GGT, lung perfusion scan, lung ventilation scan, myoglobin, plasminogen, platelet count, PET heart, procalcitonin, protein S, PT/INR, troponin, US venous Doppler extremity studies, and venography lower extremity studies.
- ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Fluorescein Angiography

SYNONYM/ACRONYM: FA.

COMMON USE: To assist in detecting vascular changes in the eyes affecting vision related to diseases such as diabetic retinopathy and macular degeneration.

AREA OF APPLICATION: Eyes.

CONTRAST: Fluorescein dye.

DESCRIPTION: Fluorescein angiography (FA) involves the color radiographic examination of the retinal vasculature following rapid IV injection of a sodium fluorescein contrast medium. A special camera allows images to be taken in sequence and manipulated by a computer to provide views of the retinal vessels during filling and emptying of the dye. The camera allows only light waves in the blue range to strike the fundus of the eye. When the fluorescein reaches the blood vessels in the eye, blue light excites the dye molecules to a higher state of activity and causes them to emit a greenish-yellow fluorescence that is recorded.

This procedure is contraindicated for

- ◆ Patients with a past history of hypersensitivity to radiographic dyes. Address concerns about nausea and vomiting, as appropriate.
- ◆ Patients with narrow-angle glaucoma if pupil dilation is performed; dilation can initiate a severe and sight-threatening open-angle attack.
- ◆ Patients with allergies to mydriatics if pupil dilation using mydriatics is performed.

INDICATIONS

- Detect arterial or venous occlusion evidenced by the reduced, delayed, or absent flow of the contrast medium through the vessels or possible vessel leakage of the medium
- Detect possible vascular disorders affecting visual acuity
- Detect presence of microaneurysms caused by hypertensive retinopathy
- Detect the presence of tumors, retinal edema, or inflammation, as evidenced by abnormal patterns or degree of fluorescence
- Diagnose and manage diabetic retinopathy
- Diagnose past reduced flow or patency of the vascular circulation of the retina, as evidenced by neovascularization
- Diagnose presence of macular degeneration and any other degeneration and any associated hemorrhaging
- Observe ocular effects resulting from the long-term use of high-risk medications

POTENTIAL DIAGNOSIS

Normal findings in

- No leakage of dye from retinal blood vessels
- Normal retina and retinal and choroidal vessels

- No evidence of vascular abnormalities, such as hemorrhage, retinopathy, aneurysms, or obstructions caused by stenosis and resulting in collateral circulation

Abnormal findings in

- Aneurysm
- Arteriovenous shunts
- Diabetic retinopathy
- Macular degeneration
- Neovascularization
- Obstructive disorders of the arteries or veins that lead to collateral circulation
- Ocular histoplasmosis
- Retinal vascular occlusion

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status may interfere with the test results.
- Presence of cataracts may interfere with fundal view.
- Ineffective dilation of the pupils may impair clear imaging.
- Allergic reaction to radiographic dye, including nausea and vomiting, may interrupt the procedure.
- Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in detecting

changes in the eye that affect vision. It may also be used as a preoperative assessment tool prior to retinal laser procedures.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or radiographic dyes.
- ▶ Obtain a history of the patient's known or suspected vision loss; changes in visual acuity, including type and cause; use of glasses or contact lenses; and eye conditions with treatment regimens.
- ▶ Obtain a history of the patient's symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- ▶ Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain and explain that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye. Explain to the patient that some discomfort may be experienced during the insertion of the IV. Inform the patient that when fluorescein dye is injected, it may cause facial flushing or nausea and vomiting. Inform the patient that a health-care provider (HCP) performs the test, in a quiet, darkened room, and that to dilate and evaluate both eyes, the test can take up to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line will be inserted to allow intermittent infusion of dye.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

- ▶ Instruct the patient to avoid eye medications (particularly miotic eye drops which may constrict the pupil preventing a clear view of the fundus and mydriatic eyedrops in order to avoid instigation of an acute open angle attack in patients with narrow angle glaucoma) for at least 1 day prior to the test.
- ▶ Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hr) after the test and has made arrangements to have someone else be responsible for transportation after the test.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

- ▶ Dilation can initiate a severe and sight-threatening open-angle attack in patients with narrow-angle glaucoma if pupil dilation is performed.
- ▶ There are a number of complications associated with venipuncture. Pain is commonly associated with needles and while pain experienced during venipuncture is usually mild, on a rare occasion the needle may strike a nerve causing severe and lasting pain. Hematoma results when blood leaks into the tissue during or after a venipuncture as evidenced by pain, bruising, and/or swelling at the venipuncture site. The swelling can cause temporary or permanent injury by compressing the surrounding nerves. Hematomas occur more often in elderly or frail patients, or those with difficult veins to access. Prolonged bleeding is a complication that occurs with patients who are taking blood thinners such as aspirin or warfarin, or who have coagulopathies such as hemophilia. Bleeding or bruising can be prevented by applying direct pressure to the site, once the needle has been removed, with gauze for a minute or two. The site should then be observed/assessed for bleeding or bruising. If no further action is required, the site can be covered by

the gauze and an adhesive bandage or paper tape. Some patients experience a vasovagal reaction during the venipuncture procedure, evidenced by sweating (diaphoresis), low blood pressure (hypotension), fainting (syncope), or near fainting (near syncope). The potential for a fall injury is a significant concern related to vasovagal reactions. Other more unusual complications of venipuncture include cellulitis, phlebitis, seizures, inadvertent arterial puncture, and sepsis. Sepsis can be caused by introduction of bacteria from the surface of the skin into the blood as the result of improper cleansing of the venipuncture site. Immunocompromised patients are at higher risk for developing this complication.

- ▶ Anaphylaxis, bronchospasm, cardiac arrest, laryngeal edema, myocardial infarction, nausea, pruritus, urticaria, or vomiting can occur in response to the dye and extravasation of the dye can occur during injection.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with medication restrictions; ensure that eye medications, especially miotics and mydriatics, have been withheld for at least 1 day prior to the test.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Seat the patient in a chair that faces the camera. Instruct the patient to look at a directed target while the eyes are examined.
- ▶ Administer the ordered mydriatic to each eye and repeat in 5 to 15 min, if dilation is to be performed. Drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (gray, semi-transparent area of the eyeball where

the cornea and sclera meet). Neither dropper nor bottle should touch the eyelashes.

- ▶ Insert an intermittent infusion device, as ordered, for subsequent injection of the contrast media or emergency medications.
- ▶ After the eyedrops are administered but before the dye is injected, color fundus photographs are taken.
- ▶ Instruct the patient to place the chin in the chin rest and gently press the forehead against the support bar. Instruct the patient to open his or her eyes wide and look at the desired target.
- ▶ Fluorescein dye is injected into the brachial vein using the intermittent infusion device, and a rapid sequence of photographs are taken and repeated after the dye has reached the retinal vascular system. Follow-up photographs are taken in 20 to 30 min.
- ▶ At the conclusion of the procedure, remove the IV needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Observe for hypersensitive reaction to the dye. The patient may become nauseous and vomit.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ **Nutritional Considerations:** Increased glucose levels may be associated with diabetes. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC)

and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) with the appropriate HCPs, particularly professionals trained in nutrition.

- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or anticipated loss of driving privileges. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Provide education regarding smoking cessation, as appropriate. Provide contact information regarding vision aids, if desired, for ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research [NIDRR], available at www.abledata.com). Information can also be obtained from the American Macular Degeneration Foundation (www.macular.org), the Glaucoma Research Foundation (www.glaucoma.org), the American Diabetes Association (www.diabetes.org), or the American Heart Association (www.americanheart.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size. Inform the patient that yellow discoloration of the skin and urine from the radiographic dye is normally present for up to 2 days. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor

progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include fructosamine, fundus photography, glucagon, glucose, glycated hemoglobin, gonioscopy, insulin, intraocular pressure, microalbumin, plethysmography, refraction, slit-lamp biomicroscopy, and visual field testing.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Folate

SYNONYM/ACRONYM: Folic acid, vitamin B₉.

COMMON USE: To assist in evaluation of diagnoses that are related to fluctuations in folate levels such as vitamin B₁₂ deficiency and malabsorption.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunochemiluminometric assay [ICMA])

	Conventional Units	SI Units (Conventional Units × 2.265)
Normal	Greater than 5.4 ng/mL	Greater than 12.2 nmol/L
Intermediate	3.4–5.4 ng/mL	7.7–12.2 nmol/L
Deficient	Less than 3.4 ng/mL	Less than 7.7 nmol/L

Values may be slightly decreased in older adults due to the effects of medications and the presence of multiple chronic or acute diseases with or without muted symptoms.

DESCRIPTION: Folate, a water-soluble vitamin, is produced by bacteria in the intestines and stored in small amounts in the liver. Dietary folate is absorbed through the intestinal mucosa and stored in the liver. Folate is necessary for normal red blood cell (RBC) and white blood cell function, DNA replication, and

cell division. Folate levels are often measured in association with serum vitamin B₁₂ determinations because vitamin B₁₂ is required for folate to enter tissue cells. Folate is an essential coenzyme in the conversion of homocysteine to methionine. Hyperhomocysteinemia resulting from folate deficiency in

pregnant women is believed to increase the risk of neural tube defects. Hyperhomocysteinemia related to low folic acid levels is also associated with increased risk for cardiovascular disease.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of megaloblastic anemia resulting from deficient folate intake or increased folate requirements, such as in pregnancy and hemolytic anemia
- Monitor the effects of prolonged parenteral nutrition
- Monitor response to disorders that may lead to folate deficiency or decreased absorption and storage

POTENTIAL DIAGNOSIS

Increased in

- Blind loop syndrome (*related to malabsorption in a segment of the intestine due to competition for absorption of folate produced by bacterial overgrowth*)
- Excessive dietary intake of folate or folate supplements
- Pernicious anemia (*related to inadequate levels of vitamin B₁₂ due to impaired absorption, resulting in increased circulating folate levels*)
- Vitamin B₁₂ deficiency (*related to vitamin B₁₂ levels inadequate to metabolize folate, resulting in increased circulating folate levels*)

Decreased in

- Chronic alcoholism (*related to insufficient intake combined with malabsorption*)
- Crohn's disease (*related to malabsorption*)
- Exfoliative dermatitis (*related to increased demand*)

- Hemolytic anemias (*related to increased demand due to shortened RBC life span caused by folate deficiency*)
- Liver disease (*related to increased excretion*)
- Malnutrition (*related to insufficient intake*)
- Megaloblastic anemia (*related to folate deficiency, which affects development of RBCs and results in anemia*)
- Myelofibrosis (*related to increased demand*)
- Neoplasms (*related to increased demand*)
- Pregnancy (*related to increased demand possibly combined with insufficient dietary intake*)
- Regional enteritis (*related to malabsorption*)
- Scurvy (*related to insufficient intake*)
- Sideroblastic anemias (*evidenced by an acquired anemia resulting from folate deficiency; iron enters and accumulates in the RBCs but cannot become incorporated in hemoglobin*)
- Sprue (*related to malabsorption*)
- Ulcerative colitis (*related to malabsorption*)
- Whipple's disease (*related to malabsorption*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may decrease folate levels include aminopterin, ampicillin, antacids, anticonvulsants, barbiturates, chloramphenicol, chloroquine, erythromycin, ethanol, glutethimide, lincomycin, metformin, methotrexate, nitrofurans, oral contraceptives, penicillin, pentamidine, phenytoin, pyrimethamine, tetracycline, and triamterene.
- Hemolysis may falsely increase folate levels.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Confusion; altered sensory perception <i>(Related to hepatic disease and encephalopathy; acute alcohol consumption; hepatic metabolic insufficiency)</i>	Disorganized thinking, restless, irritable, altered concentration and attention span, changeable mental function over the day, hallucinations; altered attention span; unable to follow directions; disoriented to person, place, time, and purpose; inappropriate affect	Treat the medical condition; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or restraints; consider pharmacological interventions; record accurate intake and output to assess fluid status; monitor blood ammonia level; monitor and trend electrolytes; determine last alcohol use; assess for symptoms of hepatic encephalopathy; assess for sleep disturbances, incoherence; protect from physical harm; administer prescribed medication, blood, blood products to treat disease
Fatigue <i>(Related to hepatic disease process; malnutrition; anemia; chemotherapy; radiation therapy)</i>	Decreased concentration; increased physical complaints; unable to restore energy with sleep; reports being tired; unable to maintain normal routine	Assess for physical cause of fatigue; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia
Nutrition <i>(Related to poor eating habits; excessive alcohol use; altered liver function; nausea; vomiting)</i>	Known inadequate caloric intake; weight loss; muscle wasting in arms and legs; stool that is pale or gray colored; skin that is flaky with loss of elasticity	Document food intake with possible calorie count; assess barriers to eating; consider using a food diary; monitor continued alcohol use as it is a barrier to adequate nutrition; monitor glucose levels; monitor daily weight; provide dietary consult with assessment of cultural food selections;

Problem	Signs & Symptoms	Interventions
Gas exchange (<i>Related to deficient oxygen capacity of the blood</i>)	Irregular breathing pattern, use of accessory muscles; altered chest excursion; adventitious breath sounds (crackles, rhonchi, wheezes, diminished breath sounds); signs of hypoxia; altered blood gas results; confusion; lethargy; cyanosis	administer multivitamin as prescribed; provide parenteral and enteral nutrition as needed; assess liver function tests ALT, AST, ALP, glucose, protein, albumin, bilirubin, folic acid, thiamine, electrolytes Monitor respiratory rate and effort based on assessment of patient condition; assess lung sounds frequently; use pulse oximetry to monitor oxygen saturation; collaborate with physician to administer oxygen as needed; elevate the head of the bed 30 degrees or higher; monitor IV fluids and avoid aggressive fluid resuscitation; assess level of consciousness; anticipate the need for possible intubation

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in detecting folate deficiency and monitoring folate therapy.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal and hematopoietic systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Protect the specimen from light.

- Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- Nutritional Considerations:** Instruct the folate-deficient patient (especially pregnant women), as appropriate, to eat foods rich in folate, such as liver, salmon, eggs, asparagus, green leafy vegetables, broccoli, sweet potatoes, beans, and whole wheat.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the patient or family.
- Educate the patient regarding access to nutritional counseling services.
- Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).

Expected Patient Outcomes:**Knowledge**

- Verbalizes understanding of the importance of reporting any difficulty breathing to facilitate timely interventions
- States understanding of information provided to support lifestyle changes that will be necessary to manage disease process

Skills

- Designs a dietary strategy that encompasses the concept of six small meals a day to better manage caloric needs
- Describes ways to conserve energy and prevent fatigue

Attitude

- Complies with the request to abstain from alcohol use
- Complies with the HCP recommendation of a dietary consult to assist in managing caloric needs appropriately

RELATED MONOGRAPHS:

- Related tests include antibodies anti-thyroglobulin, biopsy intestinal, capsule endoscopy, CBC, CBC RBC indices, complete blood count, RBC morphology, complete blood count, WBC count and differential, eosinophil count, fecal analysis, gastric acid emptying scan, gastric acid stimulation test, gastrin, G6PD, hemosiderin, homocysteine, intrinsic factor antibodies, thyroid, and vitamin B₁₂.
- Refer to the Gastrointestinal and Hematopoietic systems tables at the end of the book for related tests by body system.

Follicle-Stimulating Hormone

SYNONYM/ACRONYM: Follitropin, FSH.**COMMON USE:** To distinguish primary causes of gonadal failure from secondary causes, evaluate menstrual disturbances, and assist in infertility evaluations.**SPECIMEN:** Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units and SI Units
Child	
Prepuberty	Less than 10 international units/mL
Adult	
Male	1.4–15.5 international units/mL
Female	
Follicular phase	1.4–9.9 international units/mL
Ovulatory peak	6.2–17.2 international units/mL
Luteal phase	1.1–9.2 international units/mL
Postmenopause	19–100 international units/mL

DESCRIPTION: Follicle-stimulating hormone (FSH) is produced and stored in the anterior portion of the pituitary gland. In women, FSH promotes maturation of the graafian (germinal) follicle, causing estrogen secretion and allowing the ovum to mature. In men, FSH partially controls spermatogenesis, but the presence of testosterone is also necessary. Gonadotropin-releasing hormone secretion is stimulated by a decrease in estrogen and testosterone levels. Gonadotropin-releasing hormone secretion stimulates FSH secretion. FSH production is inhibited by an increase in estrogen and testosterone levels. FSH production is pulsatile, episodic, and cyclic and is subject to diurnal variation. Serial measurement is often required.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in distinguishing between primary and secondary (pituitary or hypothalamic) gonadal failure
- Define menstrual cycle phases as a part of infertility testing
- Evaluate ambiguous sexual differentiation in infants

- Evaluate early sexual development in girls younger than age 9 or boys younger than age 10 (precocious puberty associated with elevated levels)
- Evaluate failure of sexual maturation in adolescence
- Evaluate testicular dysfunction
- Investigate impotence, gynecomastia, and menstrual disturbances

POTENTIAL DIAGNOSIS*Increased in*

- Alcoholism (*related to suppressed secretion from the pituitary gland*)
- Castration (*oversecretion related to feedback mechanism involving decreased testosterone levels*)
- Gonadal failure (*oversecretion related to feedback mechanism involving decreased estrogen or testosterone levels*)
- Gonadotropin-secreting pituitary tumors (*related to oversecretion by tumor cells*)
- Klinefelter's syndrome (*oversecretion related to feedback mechanism involving decreased estrogen or testosterone levels*)
- Menopause (*oversecretion related to feedback mechanism involving decreased estrogen levels*)

- Orchitis (*oversecretion related to feedback mechanism involving decreased testosterone levels*)
- Precocious puberty in children (*related to oversecretion from the pituitary gland*)
- Primary hypogonadism (*oversecretion related to feedback mechanism involving decreased estrogen or testosterone levels; failure of testes or ovaries to produce sex hormones*)
- Reifenstein's syndrome (*oversecretion related to feedback mechanism involving familial partial resistance to testosterone levels*)
- Turner's syndrome (*oversecretion related to feedback mechanism involving decreased estrogen or testosterone levels*)

Decreased in

- Anorexia nervosa (*related to suppressive effects of severe caloric restriction on the hypothalamic-pituitary axis*)
- Anterior pituitary hypofunction (*underproduction resulting from dysfunctional pituitary gland*)
- Hemochromatosis (*hypogonadotropic hypogonadism related to absence of the gonadal stimulating pituitary hormones, estrogen, and testosterone; iron deposits in pituitary may affect normal production of FSH*)
- Hyperprolactinemia (*related to suppressive effect on estrogen production*)
- Hypothalamic disorders (*decreased production in response to lack of hypothalamic stimulators*)

- Polycystic ovary disease (Stein-Leventhal syndrome) (*suppressed secretion related to feedback mechanism involving increased estrogen levels*)
- Pregnancy (*related to elevated estrogen levels*)
- Sickle cell anemia (*although primary testicular dysfunction is mainly associated with sickle cell disease, related to testicular microinfarcts, hypogonadotropic hypogonadism has been reported in some men with sickle cell disease*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase FSH levels include bicalutamide, bombesin, cimetidine, clomiphene, digitalis, erythropoietin, exemestane, finasteride, gonadotropin-releasing hormone, ketoconazole, levodopa, metformin, nafarelin, naloxone, nilutamide, oxcarbazepine, pravastatin, and tamoxifen.
- Drugs that may decrease FSH levels include anabolic steroids, anticonvulsants, buserelin, estrogens, corticotropin-releasing hormone, danazol, diethylstilbestrol, goserelin, megestrol, mestranol, oral contraceptives, phenothiazine, pimozide, pravastatin, progesterone, stanozolol, tamoxifen, toremifene, and valproic acid.
- In menstruating women, values vary in relation to the phase of the menstrual cycle. Values are higher in postmenopausal women.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Family process (<i>Related to altered role performance secondary to disease progression [testicular, ovarian]</i>)	Inability to perform in supportive family role; diagnosed infertility; alterations in intimacy	Refer to family counseling; facilitate opportunities for the patient and family to express their feelings; assess the patient and family perception of the problems; evaluate patient and family weaknesses, strengths, and coping strategies; help the family and patient break down concerns into manageable parts
Self-esteem (<i>Related to altered view of self secondary to altered ability to participate in sexual intimacy; infertility; altered body image</i>)	Verbalizes feelings that express being a failure as a man or woman; dissatisfaction with present state of intimacy with significant other	Monitor for negative self-statements; assess for withdrawal; monitor for real or perceived rejection of others; encourage verbalization of self-worth; encourage a discussion of perceived changes in family role; monitor for anxiety; recommend personal and family counseling; facilitate support group participation
Fear (<i>Related to diagnosis of infertility; permanently altered sexual function [castration]; ineffective coping; unfamiliar therapeutic regime; unknown treatment outcome</i>)	Expression of fear; preoccupation with fear; increased tension; increased blood pressure; increased heart rate; vomiting; diarrhea; nausea; fatigue; weakness; insomnia; shortness of breath; increased respiratory rate; withdrawal; panic attacks	Provide specific and culturally appropriate education; assist the patient and family to recognize effective coping strategies; assist the patient to acknowledge fear; provide a safe environment to decrease fear; explore cultural influences that may enhance fear; utilize therapeutic touch as appropriate to decrease fear; collaborate with social services to address specific medical problems associated with fear; discuss fertility counseling, adoption

Problem	Signs & Symptoms	Interventions
Sexuality (<i>Related to altered sexual desire, activity; diminished intimacy; testicular, ovarian disease</i>)	Decreased sexual satisfaction; diminished sexual function; ongoing infertility	Discuss the possibility of sperm banking or harvesting ovum for future fertility needs; suggest counseling for patient and family and provide contact information; facilitate a discussion of realistic changes to sexual intimacy associated with altered estrogen and testosterone levels; provide a relaxed atmosphere to discuss sexuality concerns; provide contact information for a support group

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating disturbances in hormone levels.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and reproductive systems, as well as phase of menstrual cycle, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results and provide a supportive, non-judgmental environment when assisting

a patient through the process of fertility testing. Osteoporosis, which can result in a tendency to develop bone fractures, can occur in both female and male patients with this hormone deficiency. Encourage patients to discuss their feelings about the impact test results may have on their life and the life of their partner.

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- Discuss the implications of abnormal test results on the patient's lifestyle.
- Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Educate the patient and partner regarding access to counseling services, as appropriate.
- Educate the female patient regarding the potential effects of FSH deficiency, which may include an absence of menstrual cycles, infertility, decreased sex drive, and vaginal dryness; educate male patients regarding decreased sex drive, erectile dysfunction, and infertility.
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

- Inform the patient that multiple specimens may be required.
- Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- States understanding of family planning information provided.
- States understanding that osteoporosis can occur with this hormone deficiency and takes recommended calcium replacement.

Skills

- Demonstrates proficient self-administration of medication to treat infertility
- Describes the benefits of attending an infertility support group

Attitude

- Agrees to abstain from alcohol use
- Shares anxieties related to possible treatment to decrease barriers to the plan of care

RELATED MONOGRAPHS:

- Related tests include antibodies antisperm, BMD, *Chlamydia* group antibody, chromosome analysis, CT pituitary, estradiol, laparoscopy gynecologic, LH, MRI pituitary, prolactin, testosterone, semen analysis, and US scrotal.
- Refer to the Endocrine and Reproductive systems tables at the end of the book for related tests by body system.

Fructosamine

SYNONYM/ACRONYM: Glycated albumin.

COMMON USE: To assist in assessing long-term glucose control in diabetes.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Spectrophotometry)

Status	Conventional Units	SI Units (Conventional Units × 0.01)
Normal	174–286 micromol/L	1.74–2.86 mmol/L
Diabetic (values vary with degree of control)	210–563 micromol/L	2.10–5.63 mmol/L

This procedure is contraindicated for N/A

Decreased in
• Severe hypoproteinemia

POTENTIAL DIAGNOSIS

CRITICAL FINDINGS: N/A

Increased in

- Diabetic patients with poor glucose control

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Fundus Photography

SYNONYM/ACRONYM: N/A.

COMMON USE: To evaluate vascular and structural changes in the eye in assessing the progression of diseases such as glaucoma, diabetic retinopathy, and macular degeneration.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: This test involves the photographic examination of the structures of the eye to document the condition of the eye, detect abnormalities, and assist in following the progress of treatment.

This procedure is contraindicated for

-  Patients with narrow-angle glaucoma if pupil dilation is performed; dilation can initiate a severe and sight-threatening open-angle attack.

-  Patients with allergies to mydriatics if pupil dilation using mydriatics is performed.

INDICATIONS

- Detect the presence of choroidal nevus
- Detect various types and stages of glaucoma
- Document the presence of diabetic retinopathy
- Document the presence of macular degeneration and any other degeneration and any associated hemorrhaging

- Observe ocular effects resulting from the long-term use of high-risk medications

POTENTIAL DIAGNOSIS

Normal findings in

- Normal optic nerve and vessels
- No evidence of other ocular abnormalities

Abnormal findings in

- Aneurysm
- Atrial hypertension
- Benign intracranial hypertension from brain tumor
- Choroidal nevus
- Color vision deficiencies
- Diabetic retinopathy
- Disorders of the optic nerve
- Glaucoma
- Histoplasmosis
- Macular degeneration
- Obstructive disorders of the arteries or veins that lead to collateral circulation
- Papilledema
- Raised intracranial pressure associated with hydrocephalus
- Retinal detachment or tear
- Sick cell anemia
- Stroke

CRITICAL FINDINGS

- Detached retina

Flashers, floaters, or a veil that moves across the field of vision may indicate detached retina or retinal tear. This condition requires immediate examination by an ophthalmologist. Untreated, full retinal detachment can result in irreversible and complete loss of vision in the affected eye.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional

nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status may interfere with the test results.
- Presence of cataracts may interfere with fundal view.
- Ineffective dilation of the pupils may impair clear imaging.
- Rubbing or squeezing the eyes may affect results.
- Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure assists in detecting changes in the eye that effect vision.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially mydriatics if dilation is to be performed.
- ▶ Obtain a history of the patient's known or suspected vision loss; changes in visual acuity, including type and cause; use of glasses or contact lenses; and eye conditions with treatment regimens.
- ▶ Obtain results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- ▶ Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain and explain that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye, but no discomfort will be experienced during the examination. Inform the patient that an HCP performs the test, in a quiet, darkened room, and that to dilate and evaluate both eyes, the test can take up to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions, unless by medical direction.
- ▶ Instruct the patient to avoid eye medications (particularly miotic eye drops which may constrict the pupil preventing a clear view of the fundus and mydriatic eyedrops in order to avoid instigation of an acute open angle attack in patients with narrow angle glaucoma) for at least 1 day prior to the test.
- ▶ Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hr) after the test and has made arrangements to have someone else

be responsible for transportation after the test.

INTRATEST:

Potential Complications:

- Dilation can initiate a severe and sight-threatening open-angle attack in patients with narrow-angle glaucoma.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with medication restrictions; ensure that eye medications, especially miotics and mydriatics, have been restricted for at least 1 day prior to the test.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Seat the patient in a chair that faces the camera. Instruct the patient to look at a directed target while the eyes are examined.
- ▶ Administer the ordered mydriatic to each eye and repeat in 5 to 15 min if dilation is to be performed. Drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (gray, semi-transparent area of the eyeball where the cornea and sclera meet). Neither dropper nor bottle should touch the eyelashes.
- ▶ Instruct the patient to place the chin in the chin rest and gently press the forehead against the support bar. Instruct the patient to open his or her eyes wide and look at desired target while a sequence of photographs are taken.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ **Nutritional Considerations:** Increased glucose levels may be associated with diabetes. There is no "diabetic diet"; however, many meal-planning

approaches with nutritional goals are endorsed by the American Dietetic Association. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) with the appropriate HCPs, particularly professionals trained in nutrition.

- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or anticipated loss of driving privileges. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Emphasize, as appropriate, that good glycemic control delays the onset of and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Provide education regarding smoking cessation, as appropriate. Provide contact information regarding vision aids, if desired, for ABLEDATA (sponsored by the National Institute on Disability and Rehabilitation Research [NIDRR], available at www.abledata.com). Information can also be obtained from the American Macular Degeneration Foundation (www.macular.org), the American Diabetes Association (www.diabetes.org), or the American Heart Association (www.americanheart.org).

- ▶ Instruct the patient to avoid strenuous physical activities, like lifting heavy objects, that may increase pressure in the eye, as ordered.
- ▶ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include fluorescein angiography, fructosamine, glucagon, glucose, glycated hemoglobin, gonioscopy, insulin, intraocular pressure, microalbumin, plethysmography, refraction, slit-lamp biomicroscopy, and visual field testing.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Gallium Scan

SYNONYM/ACRONYM: Ga scan.

COMMON USE: To assist in diagnosing, evaluating, and staging tumors and in detecting areas of infection, inflammation, and abscess.

AREA OF APPLICATION: Whole body.

CONTRAST: IV radioactive gallium-67 citrate.

DESCRIPTION: Gallium imaging is a nuclear medicine study that assists in diagnosing neoplasm and inflammation activity. Gallium, which has 90% sensitivity for inflammatory disease, is readily distributed throughout plasma and body tissues. Gallium imaging is sensitive in detecting abscesses, pneumonia, pyelonephritis, active sarcoidosis, and active tuberculosis. In immunocompromised patients, such as patients with AIDS, gallium imaging can detect complications such as *Pneumocystis jiroveci* (formerly *P. carinii*) pneumonitis. Gallium imaging is useful but less commonly performed in the diagnosis and staging of some neoplasms, including Hodgkin's disease, lymphoma, melanoma, and leukemia. Imaging can be performed 6 to 72 hr after injection of the gallium and a gamma camera detects the radiation emitted from the injected radioactive material. A representative image of the distribution of the radioactive material is then obtained. Single-photon emission computed tomography (SPECT) has significantly improved the resolution and accuracy of gallium scanning and may or may not be included as part of the examination. SPECT enables images to be recorded from multiple angles around the body and reconstructs them by a

computer to produce images or "slices" representing the area of interest at different levels. Generally, the nonspecificity of gallium imaging requires correlation with other diagnostic studies, such as computed tomography, CT/PET, magnetic resonance imaging, and ultrasonography.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of infectious or inflammatory diseases
- Evaluate lymphomas
- Evaluate recurrent lymphomas or tumors after radiation therapy or chemotherapy
- Perform as a screening examination for fever of undetermined origin

POTENTIAL DIAGNOSIS

Normal findings in

- Normal distribution of gallium; some localization of the radionuclide within the liver, spleen, bone, nasopharynx, lacrimal glands, breast, and bowel is expected

Abnormal findings in

- Abscess
- Infection
- Inflammation
- Lymphoma
- Tumor

CRITICAL FINDINGS: N/A**INTERFERING FACTORS****Factors that may impair clear imaging**

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Performance of other nuclear scans within the preceding 24 to 48 hr.
- Administration of certain medications (e.g., gastrin, cholecystokinin), which may interfere with gastric emptying.

Other considerations

- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from

frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in identifying infection or other disease.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure, with support staff, and takes approximately 60 min.
- ▶ **Pediatric Considerations** Preparing children for a gallium scan depends on the age of the child. Encourage parents to be truthful about what the

child may experience during the procedure (e.g., the child may feel a pinch or minor discomfort when the IV needle is inserted) and to use words that they know their child will understand.

Toddlers and preschool-age children have a very short attention span, so the best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with the child during the procedure. Explain the importance of remaining still while the images are taken.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injection of radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**, hematoma **related to blood leakage into the tissue following needle**

insertion, infection that might occur if bacteria from the skin surface is introduced at the puncture site, or nerve injury that might occur if the needle strikes a nerve.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie still during the procedure because movement produces unclear images.
- ▶ Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization.
- ▶ IV radionuclide is administered, and the patient is instructed to return for scanning at a designated time after injection. Typical scanning occurs at 6, 24, 48, 72, 96, and/or 120 hr postinjection depending on diagnosis.
- ▶ If an abdominal abscess or infection is suspected, laxatives or enemas may be ordered before imaging at 48 or 72 hr after the injection.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.

- ▶ Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Unless contraindicated, advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ Instruct the patient to resume usual medication or activity, as directed by the HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 48 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after removing the gloves.

- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiotensin converting enzyme, biopsy bone marrow, biopsy kidney, biopsy lung, blood gases, bronchoscopy, CBC, CBC WBC and differential, chest x-ray, CT abdomen, CT pelvis, CT thoracic, culture blood, culture and smear mycobacteria, culture viral, cytology sputum, cytology urine, ESR, HIV-1/2 antibodies, IVP, lung perfusion scan, MRI chest, MRI abdomen, mediastinoscopy, pleural fluid analysis, plethysmography, PFT, pulse oximetry, renogram, US kidney, and US lymph node.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

γ -Glutamyltranspeptidase

SYNONYM/ACRONYM: Serum γ glutamyltransferase, γ glutamyl transpeptidase, GGT, SGGT.

COMMON USE: To assist in diagnosing and monitoring liver disease.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Enzymatic spectrophotometry)

Age	Conventional & SI Units
Newborn–6 mo	12–122 units/L
7 mo and older	
Male	0–30 units/L
Female	0–24 units/L

Values may be elevated in older adults due to the effects of medications and the presence of multiple chronic or acute diseases with or without muted symptoms.

DESCRIPTION: Glutaryltransferase (GGT) assists with the reabsorption of amino acids and peptides from the glomerular filtrate and intestinal lumen. Hepatobiliary, renal tubular, and pancreatic tissues contain large amounts of GGT. Other sources include the prostate gland, brain, and heart. GGT is elevated in all types of liver disease and is more responsive to biliary obstruction, cholangitis, or cholecystitis than any of the other enzymes used as markers for liver disease.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of obstructive jaundice in neonates
- Detect the presence of liver disease
- Evaluate and monitor patients with known or suspected alcohol abuse (levels rise after ingestion of small amounts of alcohol)

POTENTIAL DIAGNOSIS

Increased in

GGT is released from any damaged cell in which it is stored, so conditions that affect the liver, kidneys, or pancreas and cause cellular destruction demonstrate elevated GGT levels.

- Cirrhosis
- Diabetes with hypertension
- Hepatitis
- Hepatobiliary tract disorders
- Hepatocellular carcinoma
- Hyperthyroidism (*there is a strong association with concurrent liver abnormalities*)
- Infectious mononucleosis
- Obstructive liver disease
- Pancreatitis
- Renal transplantation
- Significant alcohol ingestion

Decreased in

- Hypothyroidism (*related to decreased enzyme production by the liver*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that may increase GGT levels include acetaminophen, alcohol, aminoglutethimide, anticonvulsants, aurothioglucose, barbiturates, captopril, cetirizine, dactinomycin, dantrolene, dexfenfluramine, estrogens, flucytosine, halothane, labetalol, medroxyprogesterone, meropenem, methyl dopa, naproxen, niacin, nortriptyline, oral contraceptives, pegaspargase, phenothiazines, piroxicam, probenecid, rifampin, streptokinase, tocainide, and trifluoperazine.
- Drugs that may decrease GGT levels include clofibrate conjugated estrogens and ursodiol.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fatigue (<i>Related to hepatic disease process; malnutrition; anemia; chemotherapy; radiation therapy</i>)	Decreased concentration; increased physical complaints; inability to restore energy with sleep; reports being tired; inability to maintain normal routine	Assess for physical cause of fatigue; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia
Confusion (<i>Related to an alteration in fluid and electrolytes, hepatic disease and encephalopathy; acute alcohol consumption; hepatic metabolic insufficiency</i>)	Disorganized thinking, restless, irritable, altered concentration and attention span, changeable mental function over the day, hallucinations; altered attention span; inability to follow directions; disoriented to person, place, time, and purpose; inappropriate affect	Treat the medical condition; correlate confusion with the need to reverse altered electrolytes; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or restraints; consider pharmacological interventions; record accurate intake and output to assess fluid status; monitor blood ammonia level; determine last alcohol use; assess for symptoms of hepatic encephalopathy such as confusion, sleep disturbances, incoherence; protect the patient from physical harm; administer lactulose as prescribed
Fluid volume (<i>Related to vomiting; decreased intake; compromised</i>)	Overload: edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted	Record daily weight and monitor trends; record accurate intake and output; collaborate with physician with

(table continues on page 832)

Problem	Signs & Symptoms	Interventions
renal function; overly aggressive fluid resuscitation; overly aggressive diuresis)	laboratory values. Deficient: decreased urinary output, fatigue, and sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status	administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes as ordered
Skin (Related to jaundice and elevated bilirubin levels; excessive scratching)	Jaundiced skin and sclera; dry skin; itching skin; damage to skin associated with scratching	Apply lotion to keep the skin moisturized; avoid alkaline soaps; discourage scratching; apply mittens if patient is not able to follow direction to avoid scratching; administer antihistamines as ordered

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing liver function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a history of IV drug use, alcohol use, high-risk sexual activity, and occupational exposure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be sent to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased GGT levels may be associated with liver disease. Dietary recommendations may be indicated and vary depending on the condition and its severity. Currently, there are no specific medications that can be given to cure hepatitis, but elimination of alcohol ingestion and a diet optimized for convalescence are commonly included in the treatment plan. A high-calorie, high-protein, moderate-fat diet with a high fluid intake is often recommended for patients with hepatitis. Treatment of cirrhosis is different because a low-protein diet may be in order if the patient's liver has lost the ability to process the end products of protein metabolism. A diet of soft foods also may be required if esophageal varices have developed. Ammonia levels may be used to determine whether protein should be

added to or reduced from the diet. The patient should be encouraged to eat simple carbohydrates and emulsified fats (as in homogenized milk or eggs) rather than complex carbohydrates (e.g., starch, fiber, and glycogen [animal carbohydrates]) and complex fats, which require additional bile to emulsify them so that they can be used. The cirrhotic patient should also be carefully observed for the development of ascites, in which case fluid and electrolyte balance requires strict attention. The alcoholic patient should be encouraged to avoid alcohol and to seek appropriate counseling for substance abuse.

- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and fear of shortened life expectancy.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Educate the patient regarding access to counseling services.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Explain to the patient that ongoing fatigue can impact his or her ability to meet personal role performance expectations.
- ▶ Explain that both physical and emotional factors can contribute to fatigue.

G

Expected Patient Outcomes:**Knowledge**

- Validates understanding that chronic fatigue that goes untreated can decrease quality of life
- Identifies how adequate nutrition may assist to decrease fatigue

Skills

- Independently reviews his or her current list of medications to evaluate if any prescription or nonprescription medications are contributing to fatigue
- Accurately develops a list of actions that can be taken to reduce fatigue and promote positive health

Attitude

- Complies with the recommendation to obtain a sleep-disorder evaluation to assess for other causes of fatigue

- Recognizes that both excess and inadequate exercise can contribute to fatigue and makes an effort to pace physical energy expenditures appropriately

RELATED MONOGRAPHS:

- Related tests include ALT, ALP ammonia, AST, bilirubin, cholangiography percutaneous transhepatic, electrolytes, HAV antibody, HBV antigen and antibody, HCV antibody, hepatobiliary scan, infectious mono screen, KUB studies, liver and spleen scan, MRI liver, TSH, US abdomen, and US liver.
- Refer to the Hepatobiliary System table at the end of the book for related tests by body system.

Gastric Analysis and Gastric Acid Stimulation Test

SYNONYM/ACRONYM: N/A.

COMMON USE: To evaluate gastric fluid and the amount of gastric acid secreted toward diagnosing gastrointestinal disorders such as ulcers, cancers, and inflammation.

SPECIMEN: Gastric fluid collected in eight plastic tubes at 15-min intervals.

NORMAL FINDINGS: (Method: Volume measurement and pH by ion-selective electrode)

Basal acid output (BAO)	Male: 0–10.5 mmol/hr Female: 0–5.6 mmol/hr
Peak acid output (PAO)	Male: 12–60 mmol/hr Female: 8–40 mmol/hr
Peak response time	Pentagastrin, intramuscular: 15–45 min Pentagastrin, subcutaneous: 10–30 min
BAO/PAO ratio	Less than 0.2

This procedure is contraindicated for

-  Patients with esophageal varices, diverticula, stenosis, malignant neoplasm of the esophagus, aortic aneurysm, severe gastric hemorrhage, and congenital heart failure.
-  Patients with a history of asthma, paroxysmal hypertension, urticaria, or other allergic conditions should not be administered histamine diphosphate.

POTENTIAL DIAGNOSIS

Increased in

Any alteration in the balance between the digestive and protective functions of the stomach that increases gastric acidity, such as hypersecretion of gastrin, use of NSAIDs, or Helicobacter pylori infection.

Appearance

- Color
 - Yellow to green indicates the presence of bile (*related to obstruction in the small intestine distal to the ampulla of Vater*)
 - Pink, red, brown indicates the presence of blood (*related to some type of gastric lesion evidenced by ulcer, gastritis, or carcinoma*)
- Microscopic evaluation
 - Red blood cells (*related to trauma or active bleeding*)
 - White blood cells (*related to inflammation of the gastric mucosa, mouth, paranasal sinuses, or respiratory tract*)

Epithelial cells (*related to inflammation of the gastric mucosa*)

Malignant cells (*related to gastric carcinoma*)

Bacteria and yeast (*related to conditions such as pyloric obstruction, pulmonary tuberculosis*)

Parasites (*related to parasitic infestation such as Giardia, H. pylori, hookworm, or Strongyloides*)

Increased Gastric Acid Output

- BAO
 - Basophilic leukemia
 - Duodenal ulcer
 - G-cell hyperplasia
 - Recurring peptic ulcer
 - Retained antrum syndrome
 - Systemic mastocytosis
 - Vagal hyperfunction
 - Zollinger-Ellison syndrome
- PAO
 - Duodenal ulcer
 - Zollinger-Ellison syndrome

Decreased in

Conditions that result in the gradual loss of function of the antrum and G cells, where gastrin is produced, will reflect decreased gastrin levels.

Decreased Gastric Acid Output

- BAO
 - Gastric ulcer
- PAO
 - Chronic gastritis
 - Gastric cancers
 - Gastric polyps
 - Gastric ulcer
 - Myxedema
 - Pernicious anemia

CRITICAL FINDINGS: N/A

Gastric Emptying Scan

SYNONYM/ACRONYM: Gastric emptying quantitation, gastric emptying scintigraphy.

COMMON USE: To visualize and assess the time frame for gastric emptying to assist in the diagnosis of diseases such as gastroenteritis and dumping syndrome.

AREA OF APPLICATION: Esophagus, stomach, small bowel.

CONTRAST: Oral radioactive technetium-99m sulfur colloid.

DESCRIPTION: A gastric emptying scan quantifies gastric emptying physiology. The procedure is indicated for patients with gastric motility symptoms, including diabetic gastroparesis, anorexia nervosa, gastric outlet obstruction syndromes, postvagotomy and postgastrectomy syndromes, and assessment of medical and surgical treatments for diseases known to affect gastric motility. A radio-nuclide is administered, and the clearance of solids and liquids may be evaluated. The images are recorded electronically, showing the gastric emptying function over time.

This procedure is contraindicated for

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risks to the fetus and mother.
- Patients with esophageal motor disorders or swallowing difficulties.

INDICATIONS

- Investigate the cause of rapid or slow rate of gastric emptying
- Measure gastric emptying rate

POTENTIAL DIAGNOSIS

Normal findings in

- Mean time emptying of liquid phase: 30 min (range, 11 to 49 min)
- Mean time emptying of solid phase: 40 min (range, 28 to 80 min)
- No delay in gastric emptying rate

Abnormal findings in

- Decreased rate:
 - Dumping syndrome
 - Duodenal ulcer
 - Malabsorption syndromes
 - Zollinger-Ellison syndrome
- Increased rate:
 - Amyloidosis
 - Anorexia nervosa
 - Diabetes
 - Gastric outlet obstruction
 - Gastric ulcer
 - Gastroenteritis
 - Gastroesophageal reflux
 - Hypokalemia, hypomagnesemia
 - Post-gastric surgery period
 - Postoperative ileus
 - Post-radiation therapy period
 - Scleroderma

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure

because of age, significant pain, or mental status.

- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Retained barium from a previous radiological procedure.
- Other nuclear scans done within the previous 24 to 48 hr.
- Administration of certain medications (e.g., gastrin, cholecystokinin), which may interfere with gastric emptying.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating the time it takes for the stomach to empty.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to eggs, latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 120 min. **Pediatric Considerations** Preparing children for a gastric emptying scan depends on the age of the child. Encourage parents to be truthful about what the child may experience during the procedure (e.g., length of time the exam will take and the need to intermittently have scans performed), stressing the importance of eating as much of the "breakfast" as possible so the test is successful, and to use words that they know their child will understand. Toddlers and preschool-age children have a very short attention span, so the best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if

appropriate, that a parent will be with the child during the procedure. Explain the importance of remaining still while the images are taken.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- ▶ Instruct the patient to restrict food and fluids for 8 hr before the scan. Inquire about allergic reactions to eggs. Protocols may vary among facilities.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary and fluid restrictions for 8 hr before the scan. Ensure that the patient does not have a known allergy to eggs.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and neurological status. Protocols may vary among facilities.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie still during the procedure because movement produces unclear images.

- ▶ Administer sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in an upright position in front of the gamma camera.
- ▶ Ask the patient to take the radionuclide mixed with water or other liquid orally, or combined with eggs for a solid study. **Pediatric Considerations** If the patient is an infant, a small amount of radionuclide will be added to the patient's feeding.
- ▶ Images are recorded over a period of time (30 to 60 min) and evaluated with regard to the amount of time the stomach takes to empty its contents.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ Monitor vital signs every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary among facilities.
- ▶ Instruct the patient to resume usual diet, fluids, medication, and activity, as directed by the HCP.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after removing the gloves.

- Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate

test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include barium swallow, biopsy kidney, biopsy liver, biopsy lung, calcitonin stimulation, calcium, capsule endoscopy, CT abdomen, esophageal manometry, EGD, fecal analysis, gastric fluid analysis and gastric acid stimulation test, gastrin and gastrin stimulation test, GI blood loss scan, glucose, glycated hemoglobin, *H. pylori* antibodies, liver and spleen scan, magnesium, PTH, UGI and small bowel series, and vitamin B₁₂.
- Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Gastrin and Gastrin Stimulation Test

SYNONYM/ACRONYM: N/A.

COMMON USE: To evaluate gastric production to assist in diagnosis of gastric disease such as Zollinger-Ellison syndrome and gastric cancer.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 0.481)
0–1 mo	70–190 pg/mL	33.7–91.4 pmol/L
2 mo–15 yr	55–185 pg/mL	26.4–89 pmol/L
16 yr and older	Less than 100 pg/mL	Less than 48.1 pmol/L

Values represent fasting levels.

Stimulation Tests

Gastrin stimulation test with secretin; 0.4 mcg/kg by IV bolus	No response or slight increase over baseline; increase of greater than 200 pg/ml above baseline is considered abnormal
--	--

Calcium may also be used as a stimulant.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Chronic gastritis (*related to hypersecretion of gastrin, use of NSAIDs, or Helicobacter pylori infection*)
- Chronic renal failure (*related to inadequate renal excretion*)
- Gastric and duodenal ulcers (*related to hypersecretion of gastrin, use of NSAIDs, or H. pylori infection*)
- Gastric carcinoma (*related to disturbance in pH favoring alkalinity, which stimulates gastrin production*)
- G-cell hyperplasia (*hyperplastic G cells produce excessive amounts of gastrin*)
- Hyperparathyroidism (*related to hypercalcemia; calcium is a potent stimulator for the release of gastrin*)

- Pernicious anemia (*related to antibodies against gastric intrinsic factor [66% of cases] and parietal cells [80% of cases that affect the stomach's ability to secrete acid; achlorhydria is a strong stimulator of gastrin production]*)
- Pyloric obstruction (*related to gastric distention, which stimulates gastrin production*)
- Retained antrum (*remaining tissue stimulates gastrin production*)
- Zollinger-Ellison syndrome (*gastrin-producing tumor*)

Decreased in

- Hypothyroidism (*related to hypocalcemia*)
- Vagotomy (*vagus nerve impulses stimulate secretion of digestive secretions; interruptions in these nerve impulses result in decreased gastrin levels*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Gastroesophageal Reflux Scan

SYNONYM/ACRONYM: Aspiration scan, GER scan, GERD scan.

COMMON USE: To assess for gastric reflux in relation to heartburn, difficulty swallowing, vomiting, and aspiration.

AREA OF APPLICATION: Esophagus and stomach.

CONTRAST: Oral radioactive technetium-99m sulfur colloid.

DESCRIPTION: The gastroesophageal reflux (GER) scan assesses gastric reflux across the esophageal sphincter. Symptoms of GER can include heartburn, regurgitation, vomiting, dysphagia, and a bitter

taste in the mouth. This procedure may be used to evaluate the medical or surgical treatment of patients with GER and to detect aspiration of gastric contents into the lungs. A radionuclide such as

technetium-99m sulfur colloid is ingested orally in orange juice and scanning studies are done immediately to assess the amount of liquid that has reached the stomach. An abdominal binder is applied and then tightened gradually to obtain images at increasing degrees of abdominal pressure: 0, 20, 40, 60, 80, and 100 mm Hg. A computer calculation determines the amount of reflux into the esophagus at each of these abdominal pressures as recorded on the images. For aspiration scans, images are taken over the lungs to detect possible tracheoesophageal aspiration of the radionuclide.

In infants, the study distinguishes between vomiting and reflux. Reflux occurs predominantly in infants younger than age 2 who are mainly on a milk diet. This procedure is indicated when an infant has symptoms such as failure to thrive, feeding problems, and episodes of wheezing with chest infection. The radionuclide is added to the infant's milk, images are obtained of the gastric and esophageal area, and the images are evaluated visually and by computer.

This procedure is contraindicated for

- Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- Patients with hiatal hernia, esophageal motor disorders, or swallowing difficulties.

INDICATIONS

- Aid in the diagnosis of GER in patients with unexplained nausea and vomiting

- Distinguish between vomiting and reflux in infants with failure to thrive, feeding problems, and wheezing combined with chest infection

POTENTIAL DIAGNOSIS

Normal findings in

- Reflux less than or equal to 4% across the esophageal sphincter

Abnormal findings in

- Reflux of greater than 4% at any pressure level
- Pulmonary aspiration

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings, dentures) within the examination field, which may inhibit organ visualization and cause unclear images.
- Retained barium from a previous radiological procedure.
- Other nuclear scans done within the previous 24 to 48 hr.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating stomach reflux.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure,

with support staff, and takes approximately 30 to 60 min. **Pediatric Considerations** Preparing children for a gastroesophageal reflux scan depends on the age of the child. Encourage parents to be truthful about what the child may experience during the procedure (e.g., the child may feel an upset stomach), stressing the importance of drinking as much of the "juice" as possible so the test is successful, and to use words that they know their child will understand. Toddlers and preschool-age children have a very short attention span, so the best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with the child during the procedure. Explain the importance of remaining still while the images are taken.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in an upright position and instruct him or her to ingest the radionuclide combined with orange juice. **Pediatric Considerations** If the patient is an infant, a small amount of radionuclide will be added to the patient's feeding.
- ▶ Place the patient in a supine position on a flat table 15 min after ingestion
- ▶ An abdominal binder with an attached sphygmomanometer is applied, and scans are taken as the binder is tightened at various pressures.
- ▶ If reflux occurs at lower pressures, an additional 30 mL of water may be given to clear the esophagus.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Instruct the patient to resume usual diet, fluids, medication, and activity, as directed by the HCP.
- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ **Nutritional Considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.
- ▶ Recognize anxiety related to test results, and be supportive of expected changes in lifestyle. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary among facilities.

RELATED MONOGRAPHS:

- ▶ Related tests include CT abdomen, esophageal manometry, gastric emptying scan, and upper GI series.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Gastrointestinal Blood Loss Scan

SYNONYM/ACRONYM: Gastrointestinal bleed localization study, GI scintigram, GI bleed scintigraphy, lower GI blood loss scan.

COMMON USE: To detect areas of active gastrointestinal bleeding or hemorrhage to facilitate surgical intervention or medical treatment. Usefulness is limited in emergency situations because of time constraints in performing the scan.

AREA OF APPLICATION: Abdomen.

CONTRAST: IV radioactive technetium-99m-labeled red blood cells.

DESCRIPTION: Gastrointestinal (GI) blood loss scan is a nuclear medicine study that assists in detecting and localizing active GI tract bleeding (2 or 3 mL/min) for the purpose of better directing endoscopic or angiographic studies. This procedure can detect bleeding if the rate is greater than 0.5 mL/min, but it is not specific for site localization or cause of bleeding. Endoscopy is the procedure of choice for diagnosing upper GI bleeding. After injection of technetium-99m-labeled red blood cells, immediate and delayed images of various views of the abdomen are obtained. The radionuclide remains in the circulation long enough to extravasate and accumulate within the bowel lumen at the site of active bleeding. This procedure is valuable for the detection and localization of recent non-GI intra-abdominal hemorrhage. Images may be taken over an extended period to show intermittent bleeding.

Pediatrics An upper GI series is usually done in the pediatric population to diagnose the cause of recurrent GI signs (bleeding) and symptoms. The etiology is often related to age. In infants,

recurrent symptoms such as vomiting after feeding, poor feeding, poor weight gain, and abdominal pain (evidenced by frequent crying during or after a feeding) may trigger an investigation. The most common causes of upper or lower GI bleeding in infants up to 1 mo include allergies to milk proteins, anorectal fissures, bacterial enteritis, coagulopathy, esophagitis, Hirschsprung's disease, intussusception, peptic ulcer, stenosis, varices, or Meckel's diverticulum. Children between 2 to 23 months are most commonly diagnosed with allergies to milk proteins, anorectal fissures, esophagitis caused by gastroesophageal reflux (GER), gastritis, intussusception, Meckel's diverticulum, NSAID-induced ulcer, and ingested foreign body. Pediatric patients 24 mo and older are most commonly diagnosed with esophageal varices, Mallory Weiss tears, peptic ulcer, related to *Helicobacter pylori* infection or peptic ulcer secondary to some other type of systemic disease (e.g., Crohn or inflammatory bowel disease [IBD]). Other abnormal findings in this age group include IBD, polyps, malignancy, sepsis, and Meckel's diverticulum.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Diagnose unexplained abdominal pain and GI bleeding

POTENTIAL DIAGNOSIS

Normal findings in

- Normal distribution of radionuclide in the large vessels with no extra-vascular activity

Abnormal findings in

- Angiodysplasia
- Aortoduodenal fistula
- Diverticulosis
- GI bleeding
- Inflammatory bowel disease
- Polyps
- Tumor
- Ulcer

CRITICAL FINDINGS

- Acute GI bleed

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the

report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Other nuclear scans done within the previous 24 to 48 hr.
- Inaccurate timing of imaging after the radionuclide injection.

Other considerations

- The examination detects only active or intermittent bleeding.
- The procedure is of little value in patients with chronic anemia or slowly decreasing hematocrit.
- The scan is less accurate for localization of bleeding sites in the upper GI tract.
- Improper injection of the radionuclide allows the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- The test is not specific, does not indicate the exact pathological condition causing the bleeding, and may miss small sites of bleeding (less than 0.5 mL/min) caused by diverticular disease or angiodysplasia.
- Physiologically unstable patients may be unable to be scanned over long periods or may need to go to surgery before the procedure is complete.

- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating for stomach and intestinal bleeding.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional

supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure, with support staff, and takes approximately 60 min to complete, with additional images taken periodically over 24 hr.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injection of radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners,** hematoma **related to blood leakage**

into the tissue following needle insertion, infection **that might occur if bacteria from the skin surface is introduced at the puncture site**, or nerve injury **that might occur if the needle strikes a nerve**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- ▶ The radionuclide is administered IV, and images are recorded immediately and every 5 min over a period of 60 min in various positions.
- ▶ The needle or catheter is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the

body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.

- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor intake and output at least every 8 hr. Compare with baseline values. Protocols may vary among facilities.
- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Instruct the patient to resume usual diet, fluids, medication, and activity, as directed by the HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ **Nutritional Considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

Related tests include antibodies anti-neutrophilic cytoplasmic, angiography

abdomen, barium enema, barium swallow, cancer antigens, capsule endoscopy, colonoscopy, CBC, CBC hematocrit, CBC hemoglobin, CT abdomen, EGD, fecal analysis, IgA, MRI abdomen, Meckel's diverticulum scan, proctosigmoidoscopy, upper GI series, and WBC scan.

Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Genetic Testing

SYNONYM/ACRONYM: Related terms: personalized medicine, companion diagnostics, molecular diagnostics.

COMMON USE: To assist in the identification of genetic mutations with implications regarding health and treatment decisions.

SPECIMEN: The facility or testing laboratory should be contacted regarding specimen collection requirements. Possible specimen types include whole blood, buccal samples, and tissue samples.

NORMAL FINDINGS: Method: Methods are specific to the study of interest and preferred specimen type. Methods include polymerase chain reaction (PCR), immunohistochemical assay, DNA probe using fluorescence in situ hybridization (FISH), gene amplification using chromogenic in situ hybridization (CISH), cell culture with karyotyping. Absence of findings consistent with genetic abnormalities related to disease or the ability to metabolize medications normally.

DESCRIPTION: Genetic testing has become an important piece of the continuously evolving health-care model. It is now possible to identify diseases before symptoms appear, predict the likelihood of disease development, and implement lifestyle or therapeutic interventions that will reduce or eliminate the effects of disease. Closer investigation into the nature of disease has sometimes revealed a more complex set of interactions than what was previously understood. While human DNA has similarities, there

are also many individual differences. Additionally, there are numerous factors such as diet, activity, environment, and stress levels that contribute to variations between one individual and another. These factors in combination with our genetic makeup impact our tendency toward the development of illnesses. Technologies made possible through the accomplishments of the Human Genome Project and a multitude of findings from other collaborative research efforts have resulted in an explosion of

diagnostic and prognostic information. The subspecialty of microbiology has been revolutionized by molecular diagnostics. Molecular diagnostics involves the identification of specific sequences of DNA. Molecular methods are used to help identify pathogens that were previously undetectable or inconsistently identified by the culture and biochemical methods available at the time. Molecular methods are also used to examine human samples for genetic disorders that are the result of both simple and complex mutations. Areas of great interest and active development related to genetic testing are in microbiology, virology, oncology, and the development of pharmaceuticals. Diagnostic and biotechnology companies are developing assays to identify gene sequences that code for proteins associated with a specific disease. Notable examples include the following:

- Mutations in the epidermal growth factor receptor (EGFR) gene: The gene encodes a protein (EGFR) associated with many types of cancer including lung, breast, and colorectal cancer.
- Mutations in the KRAS gene: If mutations are present, specific medications used to treat lung, breast, and colorectal cancers will be rendered ineffective; therefore, other options can more immediately be considered.
- Mutations in HER-2-NEU gene associated with breast cancer: If mutations are present, the cancer risk can be stratified, survival can be predicted, and selection of treatment options can be made.
- Mutations in the BRAF gene: If present, the mutations are used to identify patients, with cancers such as melanoma, who might

benefit from treatment with specific drugs that are known to be effective.

- Mutations in the P450 cytochrome series: If present, the mutations are used to predict response to specific drugs—some people will be poor metabolizers (requiring adjustments to higher doses) and some people will be ultrasensitive metabolizers (requiring adjustments to smaller doses).
- Factor V Leiden mutation: If present, this mutation indicates the person has a higher than normal risk for thromboembolism.
- Mutations in the BRCA1 and BRCA2 genes: If present, this mutation indicates the person has a high risk for development of hereditary breast or ovarian cancer. This knowledge provides the opportunity to make informed decisions regarding prophylactic mastectomy or oophorectomy.

New assays are either being developed after an effective therapy for the disease has also been developed or at the same time the treatment is being developed, as companion diagnostics. The cost-benefit analysis for the development of companion diagnostics makes a clear case for the simultaneous development of tests and targeted therapies rather than application by trial and error. The companion diagnostics model is based on the development tests that identify diseases or their related pathways, from genetic expression to production and interaction of proteins, and then to development of specific related therapies that are predicted with confidence to be effective.

Personalized medicine is the combination of identifying specific

knowledge about an individual's genetic makeup with customized therapeutics or adjustments in lifestyle, for example, genotyping for single nucleotide polymorphisms (SNPs). A SNP, or variation of a single nucleic acid in a DNA sequence, has been identified that causes malfunction of an enzyme needed for the metabolism of warfarin. Identification of this genotype has led to the development of algorithms for safe, tailored dosing and administration based on a patient's genotype, age, weight or body mass index (BMI), and gender.

Personalization can also be achieved in the customized production or compounding of pharmaceuticals with respect to the strength or formulation of the medication. Customized pharmaceuticals are being used to address dosing issues revealed by the presence of mutations in the CYP 450 series; adverse drug reactions either by undermedication or overmedication are sometimes the result of genetic programming rather than a medication error.

The System Tables at the back of the book designate the individual monographs that contain information regarding specific genetic testing.

This procedure is contraindicated for

-  Patients who are not capable of comprehending information presented in the pre- and post-testing genetic counseling sessions. The test should not be performed if the parents of an affected born or unborn child, or if the patient himself or herself, is not emotionally capable of understanding the test results and managing the ramifications of the test results. Written and

informed consent, in combination with additional education and a support system, are crucial in order to prepare the patient to make life-altering decisions.

INDICATIONS

- Assist in confirming the diagnosis of conditions associated with genetic disorders before or after associated symptoms are manifested.
- Assist in determining drug selection and appropriate dosing on an individual basis.
- Assist in forensic identifications or paternity determinations.
- Assist in monitoring the efficacy of therapeutic interventions.
- Determine the probability of passing a heritable disease to unborn children; discuss prenatal planning.
- Establish a predisposition for the development of certain diseases.
- Identify matches for organ donation.
- Identify agents of infectious disease.
- Provide an explanation of death (e.g., miscarriage, stillbirth).
- Screen for a genetic disease or condition that may affect an embryo, fetus, or neonate.

POTENTIAL DIAGNOSIS

- Identification of a condition or disease based on the results of specific genetic testing.
- Identification or disqualification of therapies related to a condition or disease based on the results of specific genetic testing.

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Proper specimen handling and transport are crucial in order to provide accurate results. The laboratory should be consulted regarding specific instructions prior to specimen collection, especially since tissue specimens are considered irretrievable.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems: N/A

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for infection or disease using genetic testing.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and related systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm the diagnosis. Inform the patient that specimen collection depends on the type of specimen required for testing. Address concerns about pain and explain that there may be some discomfort during specimen collection. (See related monographs for specific information.)
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ See the related monographs regarding special instructions for patient preparation.
- ▶ **Make sure a written and informed consent, if required, has been signed prior to specimen collection.**

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- ▶ Contact the testing laboratory prior to specimen collection in order to obtain accurate information regarding specimen collection containers, sample volumes, and specific transport instructions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Collect the appropriate specimen as described in the related body fluid analysis or culture monograph. The facility or testing laboratory should be contacted for guidelines regarding specimen collection requirements, and specimen packaging and shipping instructions.
- ▶ Perform a venipuncture if blood is the specimen required for testing. Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation, and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and provide emotional support if results are positive. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Note that depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed. Emphasize the

need to return to have additional samples taken, if ordered. Answer any questions or address any concerns voiced by the patient or family.

Patient Education: N/A

Expected Patient Outcomes: N/A

RELATED MONOGRAPHS:

▶ Related tests include α_1 -antitrypsin, Alzheimer's disease markers, amino acid screen blood & urine, amniotic fluid analysis, antibodies gliadin, anticonvulsant drugs, antidepressant drugs, antipsychotic drugs, biopsy breast, biopsy chorionic villus, biopsy skin, biopsy thyroid, bladder cancer markers, cancer antigens, CD4/CD8 enumeration,

chlamydia group antibody, chloride sweat, chromosome analysis, coagulation factors, CBC platelet count, culture and smear mycobacteria, culture bacterial (anal/genital, ear, eye, skin, and wound), cytomegalovirus, fecal analysis, glucose, group A strep screen, hexosaminidase A & B, human leukocyte antigen B27, immunosuppressant drugs, leukocyte alkaline phosphatase enzyme, newborn screening, parvovirus B19, prothrombin time and INR, red blood cell cholinesterase, and varicella antibodies.

▶ Refer to the Gastrointestinal, Genitourinary, Hematopoietic, Hepatobiliary, Immune, Musculoskeletal, and Respiratory System tables at the end of the book for related tests by body system.

Glucagon

SYNONYM/ACRONYM: N/A.

COMMON USE: To evaluate the amount of circulating glucagon toward diagnosing diseases such as hypoglycemia, pancreatic cancer, or inflammation.

SPECIMEN: Plasma (1 mL) collected in chilled, lavender-top (EDTA) tube. Specimen should be transported tightly capped and in an ice slurry.

NORMAL FINDINGS: (Method: Radioimmunoassay)

Age	Conventional Units	SI Units (Conventional Units \times 1)
Cord blood	0–215 pg/mL	0–215 ng/L
Newborn	0–1,750 pg/mL	0–1,750 ng/L
Child	0–148 pg/mL	0–148 ng/L
Adult	20–100 pg/mL	20–100 ng/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in
Glucagon is produced in the pancreas and excreted by the kidneys; conditions that affect the pancreas

and cause cellular destruction or conditions that impair the ability of the kidneys to remove glucagon from circulation will result in elevated glucagon levels.

- Acromegaly (related to stimulated production of glucagon in response to growth hormone)

- Acute pancreatitis (*related to decreased pancreatic function*)
 - Burns (*related to stress-induced release of catecholamines, which stimulates glucagon production*)
 - Cirrhosis (*pathophysiology is not well established*)
 - Cushing's syndrome (*evidenced by overproduction of cortisol, which stimulates glucagon production*)
 - Diabetes (uncontrolled) (*pathophysiology is not well established*)
 - Glucagonoma (*related to excessive production by the tumor*)
 - Hyperlipoproteinemia (*pathophysiology is not well established*)
 - Hypoglycemia (*related to response to decreased glucose level*)
 - Infection (*related to feedback loop in response to stress*)
 - Kidney transplant rejection (*related to decreased renal excretion*)
 - Pheochromocytoma (*excessive production of catecholamines stimulates increased glucagon levels*)
 - Renal failure (*related to decreased renal excretion*)
 - Stress (*related to stress-induced release of catecholamines, which stimulates glucagon production*)
 - Trauma (*related to stress-induced release of catecholamines, which stimulates glucagon production*)
- Decreased in**
 Low glucagon levels are related to decreased pancreatic function.
- Chronic pancreatitis
 - Cystic fibrosis
 - Postpancreatectomy period
- CRITICAL FINDINGS:** N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Glucose

SYNONYM/ACRONYM: Blood sugar, fasting blood sugar (FBS), postprandial glucose, 2-hr PC.

COMMON USE: To assist in the diagnosis of diabetes and to evaluate disorders of carbohydrate metabolism such as malabsorption syndrome.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube, although plasma is recommended for diagnosis of diabetes. Plasma (1 mL) collected in a gray-top (sodium fluoride) or a green-top (heparin) tube.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.0555)
Fasting		
Cord blood	45–96 mg/dL	2.5–5.3 mmol/L
Premature infant	20–80 mg/dL	1.1–4.4 mmol/L

Age	Conventional Units	SI Units (Conventional Units × 0.0555)
Newborn 2 days–2 yr	30–100 mg/dL	1.7–5.6 mmol/L
Child	60–100 mg/dL	3.3–5.6 mmol/L
Adult-older adult	Less than 100 mg/dL	Less than 5.6 mmol/L
Prediabetes or impaired fasting glucose	100–125 mg/dL	5.6–6.9 mmol/L
2-hr postprandial	65–139 mg/dL	3.6–7.7 mmol/L
Prediabetes or impaired 2-hr sample	140–199 mg/dL	7.8–11 mmol/L
Random	Less than 200 mg/dL	Less than 11.1 mmol/L

The American Diabetes Association and National Institute of Diabetes and Digestive and Kidney Diseases consider a confirmed fasting blood glucose greater than 126 mg/dL to be consistent with a diagnosis of diabetes. Values tend to increase in older adults.

DESCRIPTION: Glucose, a simple six-carbon sugar (monosaccharide), enters the diet as part of the sugars sucrose, lactose, maltose and from the complex polysaccharide, dietary starch. The body acquires most of its energy from the oxidative metabolism of glucose. Excess glucose is stored in the liver or in muscle tissue as glycogen.

Diabetes is a group of diseases characterized by hyperglycemia, or elevated glucose levels. Hyperglycemia results from a defect in insulin secretion (type 1 diabetes), a defect in insulin action, or a combination of defects in secretion and action (type 2 diabetes). The chronic hyperglycemia of diabetes may result over time in damage, dysfunction, and eventually failure of the eyes, kidneys, nerves, heart, and blood vessels. The American Diabetes Association and National Institute of Diabetes and Digestive and Kidney Disease have established criteria for diagnosing diabetes to include any combination of the following findings or confirmation of any of the individual findings by repetition on a subsequent day:

Symptoms of diabetes (e.g., polyuria, polydipsia, unexplained weight loss) in addition to a random glucose level greater than 200 mg/dL

Fasting blood glucose greater than 126 mg/dL after a minimum of an 8-hr fast

Glucose level greater than 200 mg/dL 2 hr after glucose challenge with standardized 75-mg load

Glucose measurements have been used for many years as an indicator of short-term glycemic control to identify diabetes and assist in management of the disease. Glycated hemoglobin, or hemoglobin A_{1c}, is used to indicate long-term glycemic control over a period of several months. The estimated average glucose (eAG) is a mathematical relationship between hemoglobin A_{1c} and glucose levels expressed by the formula eAG =

$$(\text{mg/dL}) = [(A_{1c} \times 28.7) - 46.7]$$

For example, eAG for a patient with an A_{1c} of 6% would be calculated as $[(6 \times 28.7) - 46.7] = 125.5$ mg/dL. Studies have documented the need for markers that reflect intermediate glycemic

control, or the period of time between 2 to 4 wk as opposed to hours or months. Many patients who appear to be well controlled according to glucose and A_{1c} values actually have significant postprandial hyperglycemia. 1,5 Anhydroglucitol is a naturally occurring monosaccharide found in most foods. It is not normally metabolized by the body and is excreted by the kidneys. During periods of normal glucose levels, there is an equilibrium between glucose and 1,5 anhydroglucitol concentrations. When blood glucose concentration rises above 180 mg/dL, the renal threshold for glucose, levels of circulating 1,5 anhydroglucitol decrease due to competitive inhibition of renal tubular absorption favoring glucose over 1,5 anhydroglucitol. As glucose is retained in the circulating blood and levels of glucose increase, correspondingly higher amounts of 1,5 anhydroglucitol are excreted in the urine. The change

in 1,5 anhydroglucitol levels is directly proportional to the severity and frequency of hyperglycemic episodes. 1,5 Anhydroglucitol concentration returns to normal after 2 wk with no recurrence of hyperglycemia. The GlycoMark assay measures 1,5 anhydroglucitol and can be used in combination with glucose and hemoglobin A_{1c} measurements to provide a more complete picture of glucose levels over time. Normal GlycoMark values for adult males are between 11 and 36 mcg/mL and for adult females 7 and 30 mcg/mL. Another indicator of intermediate glycemic control is glycated albumin; values of 0.8% to 1.4% are considered normal. Reports from the medical community indicate that over half of the U.S. population will have diabetes or prediabetes by 2020. The combined use of available markers of glycemic control will greatly improve the ability to achieve tighter, more timely glycemic control.

Comparison of Markers of Glycemic Control to Approximate Blood Glucose Concentration

1,5-Anhydroglucitol Measured Using the GlycoMark Assay	Hemoglobin A_{1c}	Estimated Blood Glucose (mg/dL)	Degree of Diabetic Control
14 mcg/mL or greater	4–5%	68–97 mg/dL	Normal/ nondiabetic
10–12 mcg/mL	4–6%	68–126 mg/dL	Well controlled
5–10 mcg/mL	6–8%	126–183 mg/dL	Moderately well controlled
2–5 mcg/mL	8–10%	183–240 mg/dL	Poorly controlled
Less than 2 mcg/mL	Greater than 10% (11–14%)	269–355 mg/dL	Very poorly controlled

Assessment of medications used to manage diabetes is an important facet of controlling the disease and its health-related complications. Drug response is an active area of study to ensure that the medications prescribed are meeting the needs of the patients who are taking them. Insulin and metformin are two commonly prescribed medications for the treatment of diabetes. See the “Insulin Antibodies” monograph for more detailed information. The AccuType Metformin Assay is a genetic test that identifies individuals who may not respond appropriately or have a suboptimal response to metformin related to a genetic mutation in the proteins responsible for transporting metformin.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of insulinoma
- Determine insulin requirements
- Evaluate disorders of carbohydrate metabolism
- Identify hypoglycemia
- Screen for diabetes

POTENTIAL DIAGNOSIS

Increased in

- Acromegaly, gigantism (*growth hormone [GH] stimulates the release of glucagon, which in turn increases glucose levels*)
- Acute stress reaction (*hyperglycemia is stimulated by the release of catecholamines and glucagon*)
- Cerebrovascular accident (*possibly related to stress*)
- Cushing's syndrome (*related to elevated cortisol*)
- Diabetes (*glucose intolerance and elevated glucose levels define diabetes*)
- Glucagonoma (*glucagon releases stored glucose; glucagon-secreting tumors will increase glucose levels*)

- Hemochromatosis (*related to iron deposition in the pancreas; subsequent damage to pancreatic tissue releases cell contents, including glucagon, resulting in hyperglycemia*)
- Liver disease (severe) (*damaged liver tissue releases cell contents, including stored glucose, into circulation*)
- Myocardial infarction (*related to stress and/or pre-existing diabetes*)
- Pancreatic adenoma (*damage to pancreatic tissue releases cell contents, including glucagon, resulting in hyperglycemia*)
- Pancreatitis (acute and chronic) (*damage to pancreatic tissue releases cell contents, including glucagon, resulting in hyperglycemia*)
- Pancreatitis due to mumps (*damage to pancreatic tissue releases cell contents, including glucagon, resulting in hyperglycemia*)
- Pheochromocytoma (*related to increased catecholamines, which increase glucagon; glucagon increases glucose levels*)
- Renal disease (severe) (*glucagon is degraded by the kidneys; when damaged kidneys cannot metabolize glucagon, glucagon levels in blood rise and result in hyperglycemia*)
- Shock, trauma (*hyperglycemia is stimulated by the release of catecholamines and glucagon*)
- Somatostatinoma (*somatostatin-producing tumor of pancreatic delta cells, associated with diabetes*)
- Strenuous exercise (*hyperglycemia is stimulated by the release of catecholamines and glucagon*)
- Syndrome X (metabolic syndrome) (*related to the development of diabetes*)
- Thyrotoxicosis (*related to loss of kidney function*)

- Vitamin B₁ deficiency (*thiamine is involved in the metabolism of glucose; deficiency results in accumulation of glucose*)

Decreased in

- Acute alcohol ingestion (*most glucose metabolism occurs in the liver; alcohol inhibits the liver from making glucose*)
- Addison's disease (*cortisol affects glucose levels; insufficient levels of cortisol result in diminished glucose levels*)
- Ectopic insulin production from tumors (adrenal carcinoma, carcinoma of the stomach, fibrosarcoma)
- Excess insulin by injection
- Galactosemia (*inherited enzyme disorder that results in accumulation of galactose in excessive proportion to glucose levels*)
- Glucagon deficiency (*glucagon controls glucose levels; hypoglycemia occurs in the absence of glucagon*)
- Glycogen storage diseases (*deficiencies in enzymes involved in conversion of glycogen to glucose*)
- Hereditary fructose intolerance (*inherited disorder of fructose metabolism; phosphates needed for intermediate steps in gluconeogenesis are trapped from further action by the enzyme deficiency responsible for fructose metabolism*)
- Hypopituitarism (*decreased levels of hormones such as adrenocorticotropic hormone [ACTH] and GH result in decreased glucose levels*)
- Hypothyroidism (*thyroid hormones affect glucose levels; decreased thyroid hormone levels result in decreased glucose levels*)
- Insulinoma (*the function of insulin is to decrease glucose levels*)
- Malabsorption syndromes (*insufficient absorption of carbohydrates*)
- Maple syrup urine disease (*inborn error of amino acid metabolism; accumulation of leucine is*

believed to inhibit the rate of gluconeogenesis, independently of insulin, and thereby diminish release of hepatic glucose stores)

- Poisoning resulting in severe liver disease (*decreased liver function correlates with decreased glucose metabolism*)
- Postgastrectomy (*insufficient intake of carbohydrates*)
- Starvation (*insufficient intake of carbohydrates*)
- von Gierke's disease (*most common glycogen storage disease; G6PD deficiency*)

CRITICAL FINDINGS

Glucose

Adults & children

- Less than 40 mg/dL (SI: Less than 2.22 mmol/L)
- Greater than 400 mg/dL (SI: Greater than 22.2 mmol/L)

Newborns

- Less than 32 mg/dL (SI: Less than 1.8 mmol/L)
- Greater than 328 mg/dL (SI: Greater than 18.2 mmol/L)

Consideration may be given to verify the critical findings before action is taken. Policies vary among facilities and may include requesting immediate recollection and retesting by the laboratory or retesting using a rapid Point of Care instrument at the bedside.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of critical values for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among

facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical value may require completion of a notification form with review by Risk Management.

Glucose monitoring is an important measure in achieving tight glycemic control. The enzymatic GDH-PQQ test method may produce falsely elevated results in patients who are receiving products that contain other sugars (e.g., oral xylose, parenterals containing maltose or galactose, and peritoneal dialysis solutions that contain icodextrin). The GDH-NAD, glucose oxidase, and glucose hexokinase methods can distinguish between glucose and other sugars.

Symptoms of decreased glucose levels include headache, confusion, hunger, irritability, nervousness, restlessness, sweating, and weakness. Possible interventions include oral or IV administration of glucose, IV or intramuscular injection of glucagon, and continuous glucose monitoring.

Symptoms of elevated glucose levels include abdominal pain, fatigue, muscle cramps, nausea, vomiting, polyuria, and thirst. Possible interventions include subcutaneous or IV injection of insulin with continuous glucose monitoring.

INTERFERING FACTORS

- Drugs that may increase glucose levels include acetazolamide, alanine, albuterol, anesthetic agents, antipyrine, atenolol, betamethasone,

cefotaxime, chlorpromazine, chlorprothixene, clonidine, clorexolone, corticotropin, cortisone, cyclic AMP, cyclopropane, dexamethasone, dextroamphetamine, diapaamide, epinephrine, enflurane, ethacrynic acid, ether, fludrocortisone, fluoxymesterone, furosemide, glucagon, glucocorticoids, homoharringtonine, hydrochlorothiazide, hydroxydione, isoniazid, maltose, meperidine, meprednisone, methyclothiazide, metolazone, niacin, nifedipine, nortriptyline, octreotide, oral contraceptives, oxyphenbutazone, pancreozymin, phenelzine, phenylbutazone, piperacetazine, polythiazide, prednisone, quinethazone, reserpine, rifampin, ritodrine, salbutamol, secretin, somatostatin, thiazides, thyroid hormone, and triamcinolone.

- Drugs that may decrease glucose levels include acarbose, acetylsalicylic acid, acipimox, alanine, allopurinol, antimony compounds, arsenicals, ascorbic acid, benzene, buformin, cannabis, captopril, carbutamide, chloroform, clofibrate, dexfenfluramine, enalapril, enprostil, erythromycin, fenfluramine, gemfibrozil, glibornuride, glyburide, guanethidine, niceritrol, nitrazepam, oral contraceptives, oxandrolone, oxymetholone, phentolamine, phosphorus, promethazine, ramipril, rotenone, sulfonyleureas, thiocarbide, tolbutamide, tromethamine, and verapamil.
- Elevated urea levels and uremia can lead to falsely elevated glucose levels.
- Extremely elevated white blood cell counts can lead to falsely decreased glucose values.
- Administration of insulin or oral hypoglycemic agents within 8 hr of a fasting blood glucose can lead to falsely decreased values.

- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated; failure to follow dietary restrictions before the fasting test can lead to falsely elevated glucose values.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Blood glucose <i>(Related to sedentary lifestyle, circulating insulin deficiency secondary to pancreatic insufficiency; excessive dietary intake; insulin resistance)</i>	Excess: Fatigue; mild dehydration; elevated blood glucose; weight loss; weakness; polyuria; polydipsia; polyphagia; blurred vision; headache; paresthesia; poor skin turgor; dry mouth; nausea; vomiting; abdominal pain; Kussmaul respirations. Deficit: tremor, sweating, decreased concentration; diaphoresis; elevated blood pressure; palpitations; headache; hunger; restlessness; lethargy; altered mental status; combativeness; altered speech; altered coordination	Check blood glucose before meals and at bedtime; administer prescribed insulin or oral agents; educate and encourage the patient to participate in glucose self-check and record results; assess readiness to learn and barriers to learning; collaborate with the health-care provider and dietician to support medical nutritional therapy; refer to dietician to assist the patient to select appropriate cultural foods; develop a plan of exercise commensurate with the patient's physical abilities; discuss lifestyle alterations necessary to support positive health management secondary to disease process; teach good hygiene and infection prevention; monitor laboratory studies that may be impacted by altered glucose and trend results (HGB A1C; BUN; Cr; electrolytes; arterial pH; magnesium; urine ketones; urine microalbumin; WBC; amylase; HGB/HCT; C-reactive protein; liver enzymes); facilitate oral hydration; correlate blood

(table continues on page 860)

Problem	Signs & Symptoms	Interventions
Infection risk <i>(Related to altered blood glucose; exposure to opportunistic hosts; poor personal hygiene; broken skin; wound presence)</i>	Increased temperature; increased heart rate and respiratory rate; chills; change in mental status; fatigue; malaise; weakness; anorexia; headache; nausea; elevated blood glucose; hypotension; diminished oxygen saturation; elevated WBC; elevated C-reactive protein	glucose with other laboratory values and medical condition(s); address the psychosocial aspects of the disease; monitor serum insulin levels Provide standard precautions in the provision of care; correlate symptoms with laboratory values and disease process; trend vital signs and laboratory values to monitor for improvement; administer prescribed antibiotics and medications for fever reduction; provide cooling measures; ensure vigilant hand hygiene; educate patient and family regarding good hand hygiene; infuse ordered IV fluids to support adequate hydration; ensure implementation of infection prevention measures with consideration of age and culture such as adequate nutrition; provide aseptic wound care; ensure good skin care; ensure good oral care; ensure adequate rest; instruct patient to avoid exposure to opportunistic hosts; send cultures to the laboratory as ordered; correlate culture findings with selected antibiotics
Noncompliance <i>(Related to refusal to accept new diagnosis; financial instability; cultural norms; complexity of the medical</i>	Insufficient disease management; alterations in blood glucose; poor self-management of medication administration; lack of supplies to support self-management;	Assess the patient's ability to and prior efforts to manage the disease process; evaluate the ability to self-manage the disease including blood glucose screening, dietary management, exercise, and medication self-administration; assess for

Problem	Signs & Symptoms	Interventions
<i>management; lack of knowledge)</i>	poor dietary control with inappropriate food selections	personal factors that may limit the patient's ability to self-perform such as visual, cognitive, and hearing; assess the financial ability to purchase the medication and supplies necessary to provide self-care; assess the level of family support; ensure the patient has the adequate knowledge to perform self-care and if not provide the necessary training; ensure the patient knows the signs and symptoms related to the disease process; teach correct dietary selections meeting cultural- and age-appropriate needs; refer to social services or home health; discuss how to manage diabetes during travel
Nutrition <i>(Related to excessive dietary intake more than body requirements, insulin deficiency, stress; anxiety; depression; cultural lifestyle; unhealthy food sources; financial restrictions)</i>	Increased thirst, increased urination, weight loss; fatigue; elevated blood glucose levels; inadequate glucose management; increased hunger	Monitor blood glucose results, refer to dietician for evaluation, administer insulin or oral agent; assess the cultural aspects of diet selection; correlate dietary intake with blood glucose and monitor trends; collaborate with a dietician to develop a cultural- and age-appropriate diet plan; correlate nutritional intake and exercise; ensure that the patient understands the relationship between caloric intake and medication (insulin, oral agent); refer to social services and dietitian as necessary

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating blood sugar levels.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of medications the patient is taking, including herbs, nutritional supplements, nutraceuticals (see Appendix H online at DavisPlus), insulin, and any other substances used to regulate glucose levels.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for at least 12 hr before specimen collection for the fasting glucose test.
- ▶ Instruct the patient to follow the instructions given for 2-hr postprandial glucose test. Some HCPs may order administration of a standard glucose solution, whereas others may instruct the patient to eat a meal with a known carbohydrate composition.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions and other pre-testing preparations; assure that food has been restricted for at least 12 hr prior to the fasting procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, as directed by the HCP.
- ▶ **Nutritional Considerations:** Increased glucose levels may be associated with diabetes. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) with the appropriate HCPs, particularly professionals trained in nutrition.

- ▶ **Social and Cultural Considerations:** Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. The ADA recommends A_{1c} testing 4 times a year for insulin-dependent type 1 or type 2 diabetes and twice a year for non-insulin-dependent type 2 diabetes. The ADA also recommends that testing for diabetes commence at age 45 for asymptomatic individuals, be considered for adults of any age who are overweight and have additional risk factors, and continue every 3 yr in the absence of symptoms.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Emphasize, if indicated, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy.
- ▶ Educate the patient regarding access to counseling services, as appropriate.
- ▶ Provide contact information, if desired, for the American Diabetes Association (ADA; www.diabetes.org) or the AHA (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Instruct the patient in the use of home test kits approved by the U.S. Food and Drug Administration, if prescribed.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient and family the signs and symptoms of hyperglycemia and hypoglycemia.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding of the signs and symptoms that could indicate an infection
- ▶ States understanding of the value of good glucose management to their overall health and longevity.

Skills

- ▶ Demonstrates proficiency in the ability to perform accurate self-check glucose checks.
- ▶ Demonstrates proficiency in the ability to perform insulin self-administration correctly or to take oral agent.

Attitude

- ▶ Complies with the medication management recommended by the health-care provider.
- ▶ Complies with dietary restrictions.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, angiography adrenal, BUN, calcium, catecholamines, cholesterol (HDL, LDL, total), cortisol, C-peptide, CT cardiac scoring, CRP, CK and isoenzymes, creatinine, DHEA, echocardiography, fecal analysis, fecal fat, fluorescein angiography, fructosamine, fundus photography, gastric emptying scan, glucagon, GTT, glycated hemoglobin A_{1c}, gonioscopy, Holter monitor, HVA, insulin, insulin antibodies, ketones, LDH and isoenzymes, lactic acid, lipoprotein electrophoresis, MRI chest, metanephrines, microalbumin, myoglobin, MI infarct scan, myocardial perfusion heart scan, plethysmography, PET heart, renin, sodium, troponin, and visual fields test.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Glucose-6-Phosphate Dehydrogenase

SYNONYM/ACRONYM: G6PD.

COMMON USE: To identify an enzyme deficiency that can result in hemolytic anemia.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Fluorescent) Qualitative assay—enzyme activity detected; quantitative assay—the following table reflects enzyme activity in units per gram of hemoglobin:

Age	Conventional Units	SI Units (Conventional Units × 0.0645)
Newborn	7.8–14.4 international units/g hemoglobin	0.5–0.93 micro units/mol hemoglobin
Adult–older adult	5.5–9.3 international units/g hemoglobin	0.35–0.60 micro units/mol hemoglobin

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in
The pathophysiology is not well understood but release of the enzymes from hemolyzed cells increases blood levels.

- Chronic blood loss (*related to reticulocytosis; replacement of RBCs*)
- Hepatic coma (*pathophysiology is unclear*)
- Hyperthyroidism (*possible response to increased basal metabolic rate and role of G6PD in glucose metabolism*)
- Idiopathic thrombocytopenic purpura

- Megaloblastic anemia (*related to reticulocytosis; replacement of RBCs*)
- Myocardial infarction (*medications [e.g., salicylates] may aggravate or stimulate a hemolytic crisis in G6PD-deficient patients*)
- Pernicious anemia (*related to reticulocytosis; replacement of RBCs*)
- Viral hepatitis (*pathophysiology is unclear*)

Decreased in

- Congenital nonspherocytic anemia
- G6PD deficiency
- Nonimmunological hemolytic disease of the newborn

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Glucose Tolerance Tests

SYNONYM/ACRONYM: Standard oral tolerance test, standard gestational screen, standard gestational tolerance test, GTT.

COMMON USE: To evaluate blood glucose levels to assist in diagnosing diseases such as diabetes.

SPECIMEN: Plasma (1 mL) collected in a gray-top (sodium fluoride) tube. Serum (1 mL) collected in a gold-, red-, or red/gray-top tube or plasma collected in a green-top (heparin) tube is also acceptable, but plasma is recommended for diagnosis. It is important to use the same type of collection container throughout the entire test.

NORMAL FINDINGS: (Method: Spectrophotometry)

G

	Conventional Units	SI Units (Conventional Units × 0.0555)
Standard Oral Glucose Tolerance (Up to 75-g Glucose Load)		
Fasting sample	Less than 100 mg/dL	Less than 5.6 mmol/L
Prediabetes or impaired fasting sample	100–125 mg/dL	5.6–6.9 mmol/L
2-hr sample	Less than 200 mg/dL	Less than 11.1 mmol/L
Prediabetes or impaired 2-hr sample	140–199 mg/dL	7.8–11 mmol/L
Tolerance Tests for Gestational Diabetes		
ACOG	Less than 141 mg/dL	Less than 7.8 mmol/L
Standard gestational screen (50-g glucose load)		
Standard gestational tolerance	ADA Threshold Recommendations for Gestational Diabetes (2012) (75-g glucose load)	ACOG Threshold Recommendations for Gestational Diabetes (2011); either Carpenter and Coustan or National Diabetes Data Group (100-g glucose load)
		Carpenter and Coustan National Diabetes Data Group

(table continues on page 866)

	Conventional Units	SI Units (Conventional Units × 0.0555)	
Fasting sample	Less than 93 mg/dL (SI: Less than 5.2 mmol/L)	Less than 95 mg/dL (SI: Less than 5.3 mmol/L)	Less than 105 mg/dL (SI: Less than 5.8 mmol/L)
1-hr sample	Less than 181 mg/dL (SI: Less than 10 mmol/L)	Less than 180 mg/dL (SI: Less than 10 mmol/L)	Less than 190 mg/dL (SI: Less than 10.5 mmol/L)
2-hr sample	Less than 154 mg/dL (SI: Less than 8.5 mmol/L)	Less than 155 mg/dL (SI: Less than 8.6 mmol/L)	Less than 165 mg/dL (SI: Less than 9.2 mmol/L)
3-hr sample	N/A	Less than 140 mg/dL (SI: Less than 7.8 mmol/L)	Less than 145 mg/dL (SI: Less than 8 mmol/L)

Plasma glucose values are reported to be 10% to 20% higher than serum values. According to recommendations of the ADA, the diagnosis of gestational diabetes is made if any of the four thresholds are met or exceeded. According to recommendations of the ACOG or National Diabetes Data Group, the diagnosis of gestational diabetes is made if any two of the four thresholds are met or exceeded.

ACOG = American Congress of Obstetricians and Gynecologists; ADA = American Diabetes Association.

DESCRIPTION: The glucose tolerance test (GTT) measures glucose levels after administration of an oral or IV carbohydrate challenge. Patients with diabetes are unable to metabolize glucose at a normal rate. The oral GTT is used for individuals who are able to eat and who are not known to have problems with gastrointestinal malabsorption. The IV GTT is used for individuals who are unable to tolerate oral glucose.

Diabetes is a group of diseases characterized by hyperglycemia or elevated glucose levels. Hyperglycemia results from a defect in insulin secretion (type 1 diabetes), a defect in

insulin action, or a combination of dysfunction secretion and action (type 2 diabetes). The chronic hyperglycemia of diabetes over time results in damage, dysfunction, and eventually failure of the eyes, kidneys, nerves, heart, and blood vessels. The American Diabetes Association and National Institute of Diabetes and Digestive and Kidney Disease have established criteria for diagnosing diabetes to include any combination of the following findings or confirmation of any of the individual findings by repetition on a subsequent day:

Symptoms of diabetes (e.g., polyuria, polydipsia, and unexplained

weight loss) in addition to a random glucose level greater than 200 mg/dL

Fasting blood glucose greater than 126 mg/dL after a minimum of an 8-hr fast

Glucose level greater than 200 mg/dL 2 hr after glucose challenge with standardized 75-mg load

The American Congress of Obstetricians and Gynecologists (ACOG) recommends screening for all pregnant women at 24 to 28 wk of gestation using patient history, clinical risk factors, or carbohydrate challenge testing. Protocol recommendations may vary among requesting health-care providers (HCPs). The ADA and International Association of Diabetes and Pregnancy Study Groups recommend that all women not previously diagnosed with diabetes undergo a 75-g OGTT at 24–28 wk of gestation because unrecognized glucose intolerance may have existed prior to the pregnancy, glucose intolerance identified during pregnancy may have continued unmonitored after pregnancy, and the frequency of diabetes in women of childbearing age has dramatically increased. The ADA also recommends a diagnosis of overt, rather than gestational, diabetes if test results meet the criteria for diabetes at the initial prenatal visit.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate abnormal fasting or postprandial blood glucose levels that do not clearly indicate diabetes

- Evaluate glucose metabolism in women of childbearing age, especially women who are pregnant and have (1) a history of previous fetal loss or birth of infants weighing 9 lb or more and/or (2) a family history of diabetes
- Identify abnormal renal tubular function if glycosuria occurs without hyperglycemia
- Identify impaired glucose metabolism without overt diabetes
- Support the diagnosis of hyperthyroidism and alcoholic liver disease, which are characterized by a sharp rise in blood glucose followed by a decline to subnormal levels

POTENTIAL DIAGNOSIS

Tolerance Increased in

- Decreased absorption of glucose:
 - Adrenal insufficiency (Addison's disease, hypopituitarism)
 - Hypothyroidism
 - Intestinal diseases, such as celiac disease and tropical sprue
 - Whipple's disease
- Increased insulin secretion:
 - Pancreatic islet cell tumor

Tolerance Impaired in

- Increased absorption of glucose:
 - Excessive intake of glucose
 - Gastrectomy
 - Gastroenterostomy
 - Hyperthyroidism
 - Vagotomy
- Decreased usage of glucose:
 - Central nervous system lesions
 - Cushing's syndrome
 - Diabetes
 - Hemochromatosis
 - Hyperlipidemia
- Decreased glycogenesis:
 - Hyperthyroidism
 - Infections
 - Liver disease (severe)
 - Pheochromocytoma
 - Pregnancy
 - Stress
 - Von Gierke disease

CRITICAL FINDINGS**Glucose****Adults & Children**

- Less than 40 mg/dL (SI: Less than 2.22 mmol/L)
- Greater than 400 mg/dL (SI: Greater than 22.2 mmol/L)

Consideration may be given to verifying the critical findings before action is taken. Policies vary among facilities and may include requesting immediate recollection and retesting by the laboratory or retesting using a rapid Point of Care instrument at the bedside.

Note and immediately report to the HCP any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Symptoms of decreased glucose levels include headache, confusion, hunger, irritability, nervousness, restlessness, sweating, and weakness.

Possible interventions include oral or IV administration of glucose, IV or intramuscular injection of glucagon, and continuous glucose monitoring.

Symptoms of elevated glucose levels include abdominal pain, fatigue, muscle cramps, nausea, vomiting, polyuria, and thirst. Possible interventions include subcutaneous or IV injection of insulin with continuous glucose monitoring.

INTERFERING FACTORS

- Drugs and substances that may increase GTT values include acetylsalicylic acid, atenolol, bendroflumethiazide, caffeine, clofibrate, fenfluramine, fluoxymesterone, glyburide, guanethidine, lisinopril, methandrostenolone, metoprolol, nandrolone, niceritrol, nifedipine, nitrendipine, norethisterone, phenformin, phenobarbital, prazosin, and terazosin.
- Drugs and substances that may decrease GTT values include acebutolol, beclomethasone, bendroflumethiazide, betamethasone, calcitonin, catecholamines, chlorothiazide, chlorpromazine, chlorthalidone, cimetidine, corticotropin, cortisone, danazol, deflazacort, dexamethasone, diapamide, diethylstilbestrol, ethacrynic acid, fludrocortisone, furosemide, glucagon, glucocorticosteroids, heroin, hydrochlorothiazide, mephenytoin, mestranol, methadone, methandrostenolone, methylprednisolone, muzolimine, niacin, nifedipine, norethindrone, norethynodrel, oral contraceptives, paramethazine, perphenazine, phenolphthalein, phenothiazine, phenytoin, pindolol, prednisolone, prednisone, propranolol, quinethazone, thiazides, triamcinolone, triamterene, and verapamil.
- The test should be performed on ambulatory patients. Impaired physical activity can lead to falsely increased values.
- Excessive physical activity before or during the test can lead to falsely decreased values.

- Failure of the patient to ingest a diet with sufficient carbohydrate content (e.g., 150 g/day) for at least 3 days before the test can result in falsely decreased values.
- The patient may have difficulty drinking the extremely sweet glucose beverage and become nauseous. Vomiting during the course of the test will cause the test to be canceled.
- Smoking before or during the test can lead to falsely increased values.
- The patient should not be under recent or current physiological stress during the test. If the patient has had recent surgery (less than 2 wk previously), an infectious disease, or a major illness (e.g., myocardial infarction), the test should be delayed or rescheduled.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Blood glucose <i>(Related to sedentary lifestyle, circulating insulin deficiency secondary to pancreatic insufficiency; excessive dietary intake; insulin resistance; pregnancy)</i>	Excess: Fatigue; mild dehydration; elevated blood glucose; weight loss; weakness; polyuria; polydipsia; polyphagia; blurred vision; headache; paresthesia; poor skin turgor; dry mouth; nausea; vomiting; abdominal pain; Kussmaul respirations. Deficit: tremor, sweating, decreased concentration; diaphoresis; elevated blood pressure; palpitations; headache; hunger; restlessness; lethargy; altered mental status; combativeness; altered speech; altered coordination	Check blood glucose before meals and at bedtime; administer prescribed insulin or oral agents; educate and encourage the patient to participate in glucose self-check and record results; assess readiness to learn and barriers to learning; collaborate with the health-care provider and dietician to support medical nutritional therapy; refer to dietician to assist the patient to select appropriate cultural foods; develop a plan of exercise commensurate with the patient's physical abilities; discuss lifestyle alterations necessary to support positive health management secondary to disease process; teach good hygiene and infection prevention; monitor laboratory studies that may be impacted by altered glucose and trend results (HGB A1C; BUN; Cr; electrolytes; arterial pH; magnesium; urine ketones;

(table continues on page 870)

Problem	Signs & Symptoms	Interventions
Nutrition <i>(Related to excessive dietary intake more than body requirements, insulin deficiency, stress; anxiety; depression; cultural lifestyle; unhealthy food sources; financial restrictions)</i>	Increased thirst, increased urination, weight loss; fatigue; elevated blood glucose levels; inadequate glucose management; increased hunger	urine microalbumin; WBC; amylase; HGB/HCT; WBC; C-reactive protein; liver enzymes); facilitate oral hydration; correlate blood glucose with other laboratory values and medical condition(s); address the psychosocial aspects of the disease; monitor serum insulin levels Monitor blood glucose results, refer to dietician for evaluation, administer insulin or oral agent; assess the cultural aspects of diet selection; correlate dietary intake with blood glucose and monitor trends; collaborate with a dietician to develop a cultural- and age-appropriate diet plan; correlate nutritional intake and exercise; ensure that the patient understands the relationship between caloric intake and medication (insulin, oral agent); refer to social services, dietitian as necessary
Infection risk <i>(Related to altered blood glucose; exposure to opportunistic hosts; poor personal hygiene; broken skin; wound presence)</i>	Increased temperature; increased heart rate and respiratory rate; chills; change in mental status; fatigue; malaise; weakness; anorexia; headache; nausea; elevated blood glucose; hypotension; diminished oxygen saturation; elevated WBC; elevated C-reactive protein	Provide standard precautions in the provision of care; correlate symptoms with laboratory values and disease process; trend vital signs and laboratory values to monitor for improvement; administer prescribed antibiotics and medications for fever reduction; provide cooling measures; perform vigilant hand hygiene; educate patient and family regarding good hand hygiene; infuse ordered IV fluids to support adequate hydration; ensure implementation of infection prevention measures with consideration of age and

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating blood sugar levels.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Inform the patient that multiple specimens may be required. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for at least 8 to 16 hr before the standard oral and standard gestational GTTs.
- ▶ Note that there are no fluid or medication restrictions unless by medical direction prior to the gestational screen.

INTRATEST:

Potential Complications:

- Note that the patient may have difficulty drinking the extremely sweet glucose beverage and become nauseous. Vomiting during the course of the test will cause the test to be canceled.
- ▶ Ensure that the patient has complied with dietary and activity restrictions as well as other pretesting preparations; ensure that food has been restricted for at least 8 to 12 hr prior to the procedure.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
 - ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
 - ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding.

- ▶ Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. Do not wait until all specimens have been collected to transport.

Standard Oral GTT

- ▶ The standard oral GTT takes 2 hr. A fasting blood glucose is determined before administration of an oral glucose load. If the fasting blood glucose is less than 126 mg/dL, the patient is given an oral glucose load.
- ▶ An oral glucose load should not be administered before the value of the fasting specimen has been received. If the fasting blood glucose is greater than 126 mg/dL, the standard glucose load is not administered and the test is canceled. The laboratory will follow its protocol as far as notifying the patient of his or her glucose level and the reason why the test was canceled. The requesting HCP will then be issued a report indicating the glucose level and the cancellation of the test. A fasting glucose greater than 126 mg/dL indicates diabetes; therefore, the glucose load would never be administered before allowing the requesting HCP to evaluate the clinical situation.
- ▶ Adults receive 75 g and children receive 1.75 g/kg ideal weight, not to exceed 75 g. The glucose load should be consumed within 5 min, and time 0 begins as soon as the patient begins to ingest the glucose load. A second specimen is collected at 2 hr, concluding the test. The test is discontinued if the patient vomits before the second specimen has been collected.

Standard Gestational Screen

- ▶ The standard gestational screen is performed on pregnant women. If results from the screen are abnormal, a full gestational GTT is performed. The gestational screen does not require a fast. The patient is given a 50-g oral glucose load. The glucose load should be consumed within 5 min, and time 0 begins as soon as the patient begins to ingest the glucose load. A specimen is collected 1 hr after ingestion. The test is discontinued if the patient

vomits before the 1-hr specimen has been collected. If the result is normal, the test may be repeated between 24 and 28 wk gestation.

Standard Gestational GTT

- ▶ The standard gestational GTT takes 3 hr. A fasting blood glucose is determined before administration of a 75-g or 100-g oral glucose load, depending on the order. If the fasting blood glucose is less than 126 mg/dL, the patient is given an oral glucose load.
- ▶ An oral glucose load should not be administered before the value of the fasting specimen has been received. *If the fasting blood glucose is greater than 126 mg/dL, the Glucola is not administered and the test is canceled (see previous explanation).*
- ▶ The glucose load should be consumed within 5 min, and time 0 begins as soon as the patient begins to ingest the glucose load. Subsequent specimens are collected at 1, 2, and 3 hr, concluding the test. The test is discontinued if the patient vomits before all specimens have been collected.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet and activity, as directed by the HCP.
- ▶ **Nutritional Considerations:** Impaired glucose tolerance may be associated with diabetes. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI)

recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) with the appropriate HCPs, particularly professionals trained in nutrition.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy.
- ▶ Discuss the implications of abnormal test results on the patient’s lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Emphasize, if indicated, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services, as appropriate.

- ▶ Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org) or the AHA (www.americanheart.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Instruct the patient in the use of home test kits approved by the U.S. Food and Drug Administration, if prescribed. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the pregnant patient that untreated gestational diabetes can increase health risks to self and fetus.
- ▶ Teach the patient that gestational diabetes may resolve after the pregnancy is over but that diabetes may reoccur later in life.

Expected Patient Outcomes:

Knowledge

- ▶ States the signs and symptoms of high and low blood sugar that should be reported to the health-care provider
- ▶ Collaborates with the dietician to formulate a meal plan that will support fetal health and control blood glucose

Skills

- ▶ Demonstrates proficiency in self-administration of prescribed

medications to control blood glucose during pregnancy correctly

- ▶ Demonstrates proficiency in the ability to perform a self-check glucose accurately

Attitude

- ▶ Complies with the recommended medication and dietary plan to control blood glucose during pregnancy
- ▶ Complies with the recommended follow-up glucose studies necessary to manage disease process

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, ALP, antibodies gliadin, angiography adrenal, biopsy intestinal, biopsy thyroid, BUN, C-peptide, capsule endoscopy, catecholamines, cholesterol (total and HDL), cortisol, creatinine, DHEAS, fecal fat, fluorescein angiography, folate, fructosamine, fundus photography, gastric acid stimulation, gastrin stimulation, glucagon, glucose, glycosylated hemoglobin, gonioscopy, 5-HIAA, insulin, insulin antibodies, ketones, metanephrines, microalbumin, oxalate, RAIU, thyroid scan, TSH, thyroxine, triglycerides, VMA, and visual fields test.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Glycated Hemoglobin

SYNONYM/ACRONYM: Hemoglobin A_{1c}, A_{1c}

COMMON USE: To monitor treatment in individuals with diabetes by evaluating their long-term glycemic control.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Chromatography)

A _{1c}	4.0–5.5%
Prediabetes	5.7–6.4%
ADA recommended treatment goal	6.5% or less

Values vary widely by method. American Diabetes Association (ADA).

DESCRIPTION: *Glycosylated or glycated hemoglobin* is the combination of glucose and hemoglobin into a ketamine; the rate at which this occurs is proportional to glucose concentration. The average life span of a red blood cell (RBC) is approximately 120 days; measurement of glycated hemoglobin is a way to monitor long-term diabetic management. The average plasma glucose can be estimated using the formula:

Average plasma glucose (mg/dL) = $[(A_{1c} \times 28.7) - 46.7]$

For example, an A_{1c} value of 6% would reflect an average plasma glucose of 125.5 mg/dL or $[(6 \times 28.7) - 46.7]$.

Diabetes is a group of diseases characterized by hyperglycemia or elevated glucose levels.

Hyperglycemia results from a defect in insulin secretion (type 1 diabetes), a defect in insulin action, or a combination of dysfunctional secretion and action (type 2 diabetes). The chronic hyperglycemia of diabetes over time results in damage, dysfunction, and eventually failure of the eyes, kidneys, nerves, heart, and blood vessels.

Hemoglobin A_{1c} levels are not age dependent and are not affected by exercise, diabetic medications, or nonfasting state before specimen collection. The hemoglobin A_{1c} assay would not be useful for patients with hemolytic anemia or abnormal hemoglobins (e.g., hemoglobin S) accompanied by abnormal RBC turnover. These patients would be screened, diagnosed, and managed using symptoms, clinical risk factors, short-term glycemic indicators (glucose), and intermediate glycemic indicators (1,5 anhydroglucitol or glycated albumin).

This procedure is contraindicated for: N/A

INDICATIONS

Assess long-term glucose control in individuals with diabetes

POTENTIAL DIAGNOSIS

Increased in

- Diabetes (poorly controlled or uncontrolled) (*related to and evidenced by elevated glucose levels*)
- Pregnancy (*evidenced by gestational diabetes*)
- Splenectomy (*related to prolonged RBC survival, which extends the amount of time hemoglobin is available for glycosylation*)

Decreased in

- Chronic blood loss (*related to decreased concentration of RBC-bound glycated hemoglobin due to blood loss*)
- Chronic renal failure (*low RBC count associated with this condition reflects corresponding decrease in RBC-bound glycated hemoglobin*)
- Conditions that decrease RBC life span (*evidenced by anemia and low RBC count, reflecting a corresponding decrease in RBC-bound glycated hemoglobin*)
- Hemolytic anemia (*evidenced by low RBC count due to hemolysis, reflecting a corresponding decrease in RBC-bound glycated hemoglobin*)
- Pregnancy (*evidenced by anemia and low RBC count, reflecting a corresponding decrease in RBC-bound glycated hemoglobin*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase glycated hemoglobin A_{1c} values include insulin and sulfonylureas.

- Drugs that may decrease glycated hemoglobin A_{1c} values include cholestyramine and metformin.
- Conditions involving abnormal hemoglobins (hemoglobinopathies) affect the reliability of glycated hemoglobin A_{1c} values, causing
 - (1) falsely increased values,
 - (2) falsely decreased values, or
 - (3) discrepancies in either direction depending on the method.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Blood glucose <i>(Related to sedentary lifestyle, circulating insulin deficiency secondary to pancreatic insufficiency; excessive dietary intake; insulin resistance; pregnancy)</i>	Excess: Fatigue; mild dehydration; elevated blood glucose; weight loss; weakness; polyuria; polydipsia; polyphagia; blurred vision; headache; paresthesia; poor skin turgor; dry mouth; nausea; vomiting; abdominal pain; Kussmaul respirations. Deficit: tremor, sweating, decreased concentration; diaphoresis; elevated blood pressure; palpitations; headache; hunger; restlessness; lethargy; altered mental status; combativeness; altered speech; altered coordination	Check blood glucose before meals and at bedtime; administer prescribed insulin or oral agents; educate and encourage the patient to participate in glucose self-check and record results; assess readiness to learn and barriers to learning; collaborate with the health-care provider and dietician to support medical nutritional therapy; collaborate with dietician to assist the patient to select appropriate cultural foods; develop a plan of exercise commensurate with the patient's physical abilities; discuss lifestyle alterations necessary to support positive health management secondary to disease process; teach good hygiene and infection prevention; monitor laboratory studies that may be impacted by altered glucose and trend results (HGB A1C; BUN; Cr; electrolytes; arterial pH; magnesium; urine ketones; urine microalbumin; WBC; amylase; HGB/HCT; WBC; C-reactive protein; liver

Problem	Signs & Symptoms	Interventions
Infection risk <i>(Related to altered blood glucose; exposure to opportunistic hosts; poor personal hygiene; broken skin; wound presence)</i>	Increased temperature; increased heart rate and respiratory rate; chills; change in mental status; fatigue; malaise; weakness; anorexia; headache; nausea; elevated blood glucose; hypotension; diminished oxygen saturation; elevated WBC; elevated C-reactive protein	enzymes); facilitate oral hydration; correlate blood glucose with other laboratory values and medical condition(s); address the psychosocial aspects of the disease; monitor serum insulin levels Provide standard precautions in the provision of care; correlate symptoms with laboratory values and disease process; trend vital signs and laboratory values to monitor for improvement; administer prescribed antibiotics and medications for fever reduction; administer cooling measures; perform vigilant hand hygiene; educate patient and family regarding good hand hygiene; infuse ordered IV fluids to support adequate hydration; ensure implementation of infection prevention measures with consideration of age and culture such as adequate nutrition; provide aseptic wound care; ensure good skin care; ensure good oral care; ensure adequate rest; instruct patient to avoid exposure to opportunistic hosts; send cultures to the laboratory as ordered; correlate culture findings with selected antibiotics
Nutrition <i>(Related to excessive dietary intake more than body requirements,</i>	Increased thirst, increased urination, weight loss; fatigue; elevated blood glucose levels;	Monitor blood glucose results, refer to dietician for evaluation, administer insulin or oral agent; assess the cultural aspects

(table continues on page 878)

Problem	Signs & Symptoms	Interventions
<i>insulin deficiency; stress; anxiety; depression; cultural lifestyle; unhealthy food sources; financial restrictions)</i>	inadequate glucose management; increased hunger	of diet selection; correlate dietary intake with blood glucose and monitor trends; collaborate with a dietician to develop a cultural- and age-appropriate diet plan; correlate nutritional intake and exercise; ensure that the patient understands the relationship between caloric intake and medication (insulin, oral agent); refer to social services, dietician
Noncompliance <i>(Related to refusal to accept new diagnosis; financial instability; cultural norms; complexity of the medical management; lack of knowledge)</i>	Insufficient disease management; alterations in blood glucose; poor self-management of medication administration; lack of supplies to support self-management; poor dietary control with inappropriate food selections	Assess the patient's ability to and prior efforts to manage the disease process; evaluate the ability to self-manage the disease including blood glucose screening, dietary management, exercise, and medication self-administration; assess for personal factors that may limit the patient's ability to self-perform such as visual, cognitive, and hearing; assess the financial ability to purchase the medication and supplies necessary to provide self-care; assess the level of family support; ensure the patient has the adequate knowledge to perform self-care and if not provide the necessary training; ensure the patient knows the signs and symptoms related to the disease process; teach correct dietary selections meeting cultural- and age-appropriate needs; refer to social services or home health; discuss how to manage diabetes during travel

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating blood sugar control over approximately the past 3 mo.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased glycosylated hemoglobin A_{1c} levels may be associated with diabetes. There is no "diabetic diet"; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The American Heart Association's Therapeutic Lifestyle Changes (TLC) diet provides goals directed at people with specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, coronary artery disease, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a "Mediterranean"-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. If triglycerides

also are elevated, the patient should be advised to eliminate or reduce alcohol. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) with the appropriate HCPs, particularly professionals trained in nutrition.

▶ **Social and Cultural Considerations:**

Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.

- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. The ADA recommends A_{1c} testing 4 times a year for patients whose treatment plan has changed or who are not meeting treatment goals and twice a year for patients who are meeting treatment goals and have stable, good glycemic control.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Emphasize, if indicated, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy.

- ▶ Educate the patient regarding access to counseling services, as appropriate.
- ▶ Provide contact information, if desired, for the American Diabetes Association (ADA; www.diabetes.org) or the AHA (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Instruct the patient in the use of home test kits approved by the U.S. Food and Drug Administration, if prescribed.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that diabetes is a disease that can adversely affect multiple body systems if not accurately controlled
- ▶ States understanding that this laboratory study is a way to assess blood glucose control over time

Skills

- ▶ Demonstrates proficiency in the ability to perform a self-check glucose accurately
- ▶ Demonstrates proficiency in the ability to perform insulin self-administration correctly or to take oral agent

Attitude

- ▶ Complies with the request for periodic A1C laboratory studies to better manage the disease process over time
- ▶ Complies with recommended diet and exercise to better control blood glucose

RELATED MONOGRAPHS:

- ▶ Related tests include C-peptide, cholesterol (total and HDL), CT cardiac scoring, creatinine/eGFR, EMG, ENG, fluorescein angiography, fructosamine, fundus photography, gastric emptying scan, glucagon, glucose, glucose tolerance tests, insulin, insulin antibodies, ketones, microalbumin, plethysmography, slit-lamp biomicroscopy, triglycerides, and visual fields test.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Gonioscopy

SYNONYM/ACRONYM: N/A.

COMMON USE: To detect abnormalities in the structure of the anterior chamber of the eye such as in glaucoma.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: Gonioscopy is a technique used for examination of the anterior chamber structures of the eye (i.e., the trabecular meshwork and the anatomical relationship of the trabecular meshwork to the iris). The trabecular meshwork is the drainage system of the eye, and gonioscopy is performed to determine if the drainage angle is damaged, blocked, or clogged. Gonioscopy in combination with biomicroscopy is considered to be the most thorough basis to confirm a diagnosis of glaucoma and to differentiate between open-angle and angle-closure glaucoma. The angle structures of the anterior chamber are normally not visible because light entering the eye through the cornea is reflected back into the anterior chamber. Placement of a special contact lens (goniolens) over the cornea allows reflected light to pass back through the cornea and onto a reflective mirror in the contact lens. It is in this way that the angle structures can be visualized. There are two types of gonioscopy: indirect and direct. The more commonly used indirect technique employs a mirrored goniolens and biomicroscope. Direct gonioscopy is performed with a

gonioscope containing a dome-shaped contact lens known as a gonioprism. The gonioprism eliminates internally reflected light, allowing direct visualization of the angle. Interpretation of visual examination is usually documented in a colored hand-drawn diagram. Scheie's classification is used to standardize definition of angles based on appearance by gonioscopy. Shaffer's classification is based on the angular width of the angle recess.

This procedure is contraindicated for: N/A

INDICATIONS

- Assessment of peripheral anterior synechiae (PAS)
- Conditions affecting the ciliary body
- Degenerative conditions of the anterior chamber
- Evaluation of glaucoma (confirmation of normal structures and estimation of angle width)
- Growth or tumor in the angle
- Hyperpigmentation
- Post-trauma evaluation for angle recession
- Suspected neovascularization of the angle
- Uveitis

POTENTIAL DIAGNOSIS

Scheie's Classification Based on Visible Angle Structures

Classification	Appearance
Wide open	All angle structures seen
Grade I narrow	Difficult to see over the iris root
Grade II narrow	Ciliary band obscured
Grade III narrow	Posterior trabeculum hazy
Grade IV narrow	Only Schwalbe's line visible

Shaffer's Classification Based on Angle Width

Classification	Appearance
Wide open (20°–45°)	Closure improbable
Moderately narrow (10°–20°)	Closure possible
Extremely narrow (less than 10°)	Closure possible
Partially/totally closed	Closure present

Normal findings in

- Normal appearance of anterior chamber structures and wide, unblocked, normal angle

Abnormal findings in

- Corneal endothelial disorders (Fuchs' endothelial dystrophy, irido-corneal endothelial syndrome)
- Glaucoma
- Lens disorders (cataract, displaced lens)
- Malignant ocular neoplasm in angle
- Neovascularization in angle
- Ocular hemorrhage
- PAS
- Schwartz's syndrome
- Trauma
- Tumors
- Uveitis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status may interfere with the test results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating the eye for disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's known or suspected vision loss; changes in visual acuity, including type and cause, use of glasses or contact lenses, eye conditions with treatment regimens, and eye surgery; as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding

the importance of keeping the eyes open for the test.

- ▶ Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain related to the procedure. Explain that no pain will be experienced during the test, but there may be moments of discomfort. Explain that some discomfort may be experienced after the test when the numbness wears off from anesthetic drops administered prior to the test. Inform the patient that the test is performed by a health-care provider (HCP) or optometrist specially trained to perform this procedure and takes about 5 min to complete.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Seat the patient comfortably. Instill topical anesthetic in each eye, as ordered, and allow time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (gray, semitransparent area of the eyeball where the cornea and sclera meet). Neither the dropper

nor the bottle should touch the eyelashes.

- ▶ Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. Ask the patient to open his or her eyes wide and look at desired target. Explain that the HCP or optometrist will place a lens on the eye while a narrow beam of light is focused on the eye.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or anticipated loss of driving privileges. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include fundus photography, pachymetry, slit-lamp biomicroscopy, and visual field testing.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Gram Stain

SYNONYM/ACRONYM: N/A.

COMMON USE: To provide a quick reference for gram-negative or gram-positive organisms to assist in medical management.

SPECIMEN: Blood, biopsy specimen, or body fluid as collected for culture.

NORMAL FINDINGS: N/A.

DESCRIPTION: Gram stain is a technique commonly used to identify bacterial organisms on the basis of their specific staining characteristics. The method involves smearing a small amount of specimen on a slide, and then exposing it to gentian or crystal violet, iodine, alcohol, and safranin O. Gram-positive bacteria retain the gentian or crystal violet and iodine stain complex after a decolorization step and appear purple-blue in color. Gram-negative bacteria do not retain the stain after decolorization but can pick up the pink color of the safranin O counterstain. Gram stains provide information regarding the adequacy of a sample. For example, a sputum Gram stain showing greater than 25 squamous epithelial cells per low-power field, regardless of the number of polymorphonuclear white blood cells, indicates contamination of the specimen with saliva, and the specimen should be rejected for subsequent culture. Gram stains are reviewed over a number of fields for an impression of the quantity

of organisms present, which reflects the extent of infection. For example, a Gram stain of unspun urine showing the occasional presence of bacteria per low-power field suggests a correlating colony count of 10,000 bacteria/mL, while the presence of bacteria in most fields is clinically significant and suggests greater than 100,000 bacteria/mL of urine. Gram stain results should be correlated with culture and sensitivity results to interpret the significance of isolated organisms and to select appropriate antibiotic therapy.

This procedure is contraindicated for: N/A

INDICATIONS

- Provide a rapid determination of the acceptability of the specimen for further analysis
- Provide rapid, presumptive information about the type of potential pathogen present in the specimen (i.e., gram-positive bacteria, gram-negative bacteria, or yeast)

POTENTIAL DIAGNOSIS

Gram Positive

<i>Actinomadura</i>	<i>Actinomyces</i>	<i>Bacillus</i>	<i>Clostridium</i>	<i>Corynebacterium</i>
<i>Enterococcus</i>	<i>Erysipelothrix</i>	<i>Lactobacillus</i>	<i>Listeria</i>	<i>Micrococcus</i>
<i>Mycobacterium</i> (gram variable)	<i>Peptostreptococcus</i>	<i>Propionibacterium</i>	<i>Rhodococcus</i>	<i>Staphylococcus</i>
<i>Streptococcus</i>				

Gram Negative

<i>Acinetobacter</i>	<i>Aeromonas</i>	<i>Alcaligenes</i>	<i>Bacteroides</i>	<i>Bordetella</i>
<i>Borrelia</i>	<i>Brucella</i>	<i>Campylobacter</i>	<i>Citrobacter</i>	<i>Chlamydia</i>
<i>Enterobacter</i>	<i>Escherichia</i>	<i>Flavobacterium</i>	<i>Francisella</i>	<i>Fusobacterium</i>
<i>Gardnerella</i>	<i>Haemophilus</i>	<i>Helicobacter</i>	<i>Klebsiella</i>	<i>Legionella</i>
<i>Leptospira</i>	<i>Moraxella</i>	<i>Neisseria</i>	<i>Pasteurella</i>	<i>Plesiomonas</i>
<i>Porphyromonas</i>	<i>Prevotella</i>	<i>Proteus</i>	<i>Pseudomonas</i>	<i>Rickettsia</i>
<i>Salmonella</i>	<i>Serratia</i>	<i>Shigella</i>	<i>Vibrio</i>	<i>Xanthomonas</i>
<i>Yersinia</i>				

Acid Fast or Partial Acid Fast

<i>Nocardia</i>	<i>Mycobacterium</i>
-----------------	----------------------

Note: *Treponema* species are classified as gram-negative spirochetes, but they are most often visualized using dark-field or silver-staining techniques.

CRITICAL FINDINGS 

- Any positive results in blood, cerebrospinal fluid, or any body cavity fluid.

Note and immediately report to the requesting health-care provider (HCP) any positive results and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary

among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Very young, very old, or dead cultures may react atypically to the Gram stain technique.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identifying the presence of pathogenic organisms.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal, genitourinary, immune, reproductive, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that the time it takes to collect a proper specimen varies according to the patient's level of cooperation as well as the specimen collection site. Address concerns about pain and explain that there may be some discomfort during the procedure.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label

the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

- ▶ Specific collection instructions are found in the associated culture monographs.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Administer antibiotics as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include amniotic fluid analysis, relevant biopsies, bronchoscopy, cultures bacterial and viral, CSF analysis, CBC, pericardial fluid analysis, peritoneal fluid analysis, pleural fluid analysis, procalcitonin, synovial fluid analysis, and UA.
- ▶ Refer to the Gastrointestinal, Genitourinary, Immune, Reproductive, and Respiratory systems tables at the end of the book for related tests by body system.

Group A Streptococcal Screen

SYNONYM/ACRONYM: Strep screen, rapid strep screen, direct strep screen.

COMMON USE: To detect a group A streptococcal infection such as strep throat.

SPECIMEN: Throat swab (two swabs should be submitted so that a culture can be performed if the screen is negative).

NORMAL FINDINGS: (Method: Enzyme immunoassay or latex agglutination) Negative.

DESCRIPTION: Rheumatic fever is a possible sequela to an untreated streptococcal infection. Early diagnosis and treatment appear to lessen the seriousness of symptoms during the acute phase and overall duration of the infection and sequelae. The onset of strep throat is sudden and includes symptoms such as chills, headache, sore throat, malaise, and exudative gray-white patches on the tonsils or pharynx. The group A streptococcal screen should not be ordered unless the results would be available within 1 to 2 hr of specimen collection to make rapid, effective therapeutic decisions. A positive result can be a reliable basis for the initiation of therapy. A negative result is presumptive for infection and should be backed up by culture results. In general, specimens showing growth of less than 10 colonies on culture yield negative results by the rapid screening method. Evidence of group A streptococci disappears rapidly after the initiation of antibiotic therapy. A nucleic acid probe method has also been developed for rapid detection of group A streptococci.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the rapid determination of the presence of group A streptococci

POTENTIAL DIAGNOSIS

Positive findings in

- Rheumatic fever
- Scarlet fever
- Strep throat
- Streptococcal glomerulonephritis
- Tonsillitis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Polyester (rayon or Dacron) swabs are favored over cotton for best chance of detection. Fatty acids are created on cotton fibers during the sterilization process. Detectable target antigens on the streptococcal cell wall are destroyed without killing the organism when there is contact between the specimen and the fatty acids on the cotton collection swab. False-negative test results can be obtained on specimens collected with cotton tip swabs.

Negative strep screens should always be followed with a traditional culture.

- Sensitivity of the method varies among manufacturers.

- Adequate specimen collection in children may be difficult to achieve, which explains the higher percentage of false-negative results in this age group.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to exposure to bacterial organisms secondary to, inadequate defense mechanism; insufficient nutrition; chronic disease</i>)	Temperature; increased heart rate; increased blood pressure; shaking; chills; mottled skin; lethargy; fatigue; swelling; pain; night sweats; confusion; positive Streptococcal throat swab; swollen tender lymph nodes in neck; headache; rash; vomiting; red, tender, pus-filled tonsils	Promote good hygiene; assist with hygiene as needed; administer prescribed antibiotics, antipyretics; provide cooling measures; monitor vital signs and trend temperatures; encourage oral fluids; adhere to standard or universal precautions; obtain cultures as ordered; assess nutritional status and provide supplements as needed
Airway (<i>Related to infection; inflammation</i>)	Difficulty swallowing; tonsils that are red, swollen, with puss or white patches; swollen tender lymph nodes in neck; dyspnea; tachypnea	Assess respiratory characteristics (rate, rhythm, depth, accessory muscle use); use pulse oximetry; administer prescribed oxygen; administer prescribed antibiotics; provide humidification of oxygen as appropriate
Fatigue (<i>Related to infection and inflammation</i>)	Report of tiredness; inability to maintain activities of daily living at current level; inability to restore energy after rest or sleep	Discuss the implementation of energy conservation activities (even pace when working, frequent rest periods, items in easy reach, push items instead of pulling); limit naps to increase nighttime sleeping; set priorities for energy expenditures; administer ordered antibiotics

Problem	Signs & Symptoms	Interventions
Health management (<i>Related to inadequate access to care; low income; inadequate support systems; cultural influences</i>)	Unable to or fails to recognize or process information toward improving health and preventing illness with associated mental and physical effects; fails to keep appointments; fails to comply with recommended therapeutic regime	Collaborate with health-care provider to develop a plan of care that supports health; ensure patient adheres to recommended medication regime; ensure patient complies with health-care follow-up appointments; assess diet and lifestyle choices; assess health history; identify specific questions and reservations related to health management

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identifying a streptococcal infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a history of prior antibiotic therapy.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Before specimen collection, verify with the laboratory whether wet or dry swabs are preferred for collection.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the swabbing procedure.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Vigorous swabbing of both tonsillar pillars and the posterior throat enhances the probability of streptococcal antigen detection.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Administer antibiotics as ordered, and emphasize to the patient or caregiver the importance of completing the entire course of antibiotic therapy even if no symptoms are present.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ Discusses the effects of noncompliance on overall health
- ▶ States importance of completing antibiotic therapy to prevent infection recurrence

Skills

- ▶ Demonstrates proficiency in self-administration of prescribed antibiotics
- ▶ Relates symptoms of infection that should be reported to the HCP

Attitude

- ▶ Recognizes the importance of accepting financial assistance as necessary to maintain health
- ▶ Exhibits willingness to break long-held habits to improve health

RELATED MONOGRAPHS:

- ▶ Related laboratory tests include analgesic and antipyretic drugs, antimicrobial drugs, ASO, chest x-ray, CBC, culture (throat, viral), and Gram stain.
- ▶ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Growth Hormone, Stimulation and Suppression Tests

SYNONYM/ACRONYM: Somatotropic hormone, somatotropin, GH, hGH.

COMMON USE: To assess pituitary function and evaluate the amount of secreted growth hormone to assist in diagnosing diseases such as gigantism and dwarfism.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

Growth Hormone

Age	Conventional Units	SI Units (Conventional Units × 1)
Cord blood	8–40 ng/mL	8–40 mcg/L
1 day	5–50 ng/mL	5–50 mcg/L
1 wk	5–25 ng/mL	5–25 mcg/L
Child	2–10 ng/mL	2–10 mcg/L

Age	Conventional Units	SI Units (Conventional Units × 1)
Adult		
Male	0–5 ng/mL	0–5 mcg/L
Female	0–10 ng/mL	0–10 mcg/L
Male older than 60 yr	0–10 ng/mL	0–10 mcg/L
Female older than 60 yr	0–14 ng/mL	0–14 mcg/L
Stimulation Tests		
Rise above baseline	Greater than 5 ng/mL	Greater than 5 mcg/L
Peak response	Greater than 10 ng/mL	Greater than 10 mcg/L
Suppression Tests	0–2 ng/mL	0–2 mcg/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Production of GH is modulated by numerous factors, including stress, exercise, sleep, nutrition, and response to circulating levels of GH.

- Acromegaly
- Anorexia nervosa
- Cirrhosis
- Diabetes (uncontrolled)
- Ectopic GH secretion (neoplasms of stomach, lung)

- Exercise
- Gigantism (pituitary)
- Hyperpituitarism
- Laron dwarfism
- Malnutrition
- Renal failure
- Stress

Decreased in

- Adrenocortical hyperfunction (*inhibits secretion of GH*)
- Dwarfism (pituitary) (*related to GH deficiency*)
- Hypopituitarism (*related to lack of production*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Ham's Test for Paroxysmal Nocturnal Hemoglobinuria

SYNONYM/ACRONYM: Acid hemolysis test for PNH.

COMMON USE: To assist in diagnosing a rare condition called paroxysmal nocturnal hemoglobinuria (PNH), wherein red blood cells undergo lysis during and after sleep with hemoglobin excreted in the urine.

SPECIMEN: Whole blood (5 mL) collected in lavender-top (EDTA) tube and serum (3 mL) collected in red-top tube.

NORMAL FINDINGS: (Method: Acidified hemolysis) No hemolysis seen.

This procedure is contraindicated for: N/A

Decreased in: N/A

CRITICAL FINDINGS: N/A

POTENTIAL DIAGNOSIS

Increased in

- Congenital dyserythropoietic anemia, type II
- PNH

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Haptoglobin

SYNONYM/ACRONYM: Hapto, HP, Hp.

COMMON USE: To assist in evaluating for intravascular hemolysis related to transfusion reactions, chronic liver disease, hemolytic anemias, and tissue inflammation or destruction.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunoturbidimetric)

Age	Conventional Units	SI Units (Conventional Units × 0.01)
Newborn	5–48 mg/dL	0.05–0.48 g/L
6 mo–16 yr	25–138 mg/dL	0.25–1.38 g/L
Adult	15–200 mg/dL	0.15–2 g/L

DESCRIPTION: Haptoglobin is an α_2 -globulin produced in the liver.

It binds with the free hemoglobin released when red blood cells

(RBCs) are lysed. The complexed hemoglobin is then removed from circulation by the spleen.

Haptoglobin is used as a marker for intravascular hemolysis because the amount of free hemoglobin from a significant number of lysed RBCs will exceed the amount of haptoglobin normally available for binding. In conditions such as hemolytic anemia (e.g., drug induced, inherited, acute transfusion reaction) the liver is unable to compensate so consumption exceeds production, and haptoglobin levels are decreased.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the investigation of suspected transfusion reaction
- Evaluate known or suspected chronic liver disease, as indicated by decreased levels of haptoglobin
- Evaluate known or suspected disorders characterized by excessive RBC hemolysis, as indicated by decreased levels of haptoglobin
- Evaluate known or suspected disorders involving a diffuse inflammatory process or tissue destruction, as indicated by elevated levels of haptoglobin

POTENTIAL DIAGNOSIS

Increased in

Haptoglobin is an acute-phase reactant protein, and any condition that stimulates an acute-phase response will result in elevations of haptoglobin.

- Biliary obstruction
- Disorders involving tissue destruction, such as cancers, burns, and acute myocardial infarction
- Infection or inflammatory diseases, such as ulcerative colitis, arthritis, and pyelonephritis
- Neoplasms
- Steroid therapy

Decreased in

- Autoimmune hemolysis (*related to increased excretion rate of haptoglobin bound to free hemoglobin; rate of excretion exceeds the liver's immediate ability to replenish*)
- Hemolysis due to drug reaction (*related to increased excretion rate of haptoglobin bound to free hemoglobin; rate of excretion exceeds the liver's immediate ability to replenish*)
- Hemolysis due to mechanical destruction (e.g., artificial heart valves, contact sports, subacute bacterial endocarditis) (*related to increased excretion rate of haptoglobin bound to free hemoglobin; rate of excretion exceeds the liver's immediate ability to replenish*)
- Hemolysis due to RBC membrane or metabolic defects (*related to increased excretion rate of haptoglobin bound to free hemoglobin; rate of excretion exceeds the liver's immediate ability to replenish*)
- Hemolysis due to transfusion reaction (*related to increased excretion rate of haptoglobin bound to free hemoglobin; rate of excretion exceeds the liver's immediate ability to replenish*)
- Hypersplenism (*related to increased excretion rate of haptoglobin bound to free hemoglobin due to increased red blood cell destruction; rate of excretion exceeds the liver's immediate ability to replenish*)
- Ineffective hematopoiesis due to conditions such as folate deficiency or hemoglobinopathies (*related to decreased numbers of RBCs or dysfunctional binding in the presence of abnormal hemoglobins*)
- Liver disease (*related to decreased production*)
- Pregnancy (*related to effect of estrogen*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase haptoglobin levels include anabolic steroids, danazol, ethylestrenol, fluoxymesterone, methandrosterone, norethandrolone, oxandrolone, oxymetholone, and stanozolol.
- Drugs that may decrease haptoglobin levels include acetanilid, aminosalicic acid, chlorpromazine, dapsone, dextran, diphenhydramine, furadaltone, furazolidone, isoniazid, nitrofurantoin, norethindrone, oral contraceptives, quinidine, resorcinol, stibophen, tamoxifen, thiazolsulfone, and tripeleminamine.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with evaluating causes of red blood cell loss.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic, hepatobiliary, and immune systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to immediately report symptoms of hemolysis, including chills, fever, flushing, back pain, and fast heartbeat, to the HCP.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, AST, bilirubin, blood group and type, CBC, CBC RBC count, CBC RBC indices, CBC RBC morphology, Coombs' antiglobulin, folate, G6PD, GGT, Ham's test, hepatobiliary scan, and osmotic fragility.
- ▶ Refer to the Hematopoietic, Hepatobiliary, and Immune systems tables at the end of the book for related tests by body system.

Helicobacter Pylori Antibody

SYNONYM/ACRONYM: *H. pylori*.

COMMON USE: To test blood for findings that would indicate past or current *Helicobacter pylori* infection.

SPECIMEN: Serum (1 mL) collected in a plain gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 h of collection.

NORMAL FINDINGS: (Method: Enzyme-linked immunosorbent assay [ELISA]) Negative.

DESCRIPTION: There is a strong association between *Helicobacter pylori* infection and gastric cancer, duodenal and gastric ulcer, and chronic gastritis. Immunoglobulin G (IgG) antibodies can be detected for up to 1 yr after treatment. The presence of *H. pylori* can also be demonstrated by a positive urea breath test, positive stool culture, or positive endoscopic biopsy. Patients with symptoms and evidence of *H. pylori* infection are considered to be infected with the organism; patients who demonstrate evidence of *H. pylori* but are without symptoms are said to be colonized.

The urea breath test is an accurate way to identify the presence of *H. pylori*. For the urea breath test, the patient swallows a capsule containing urea made from an isotope of carbon. If *H. pylori* is present in the stomach, the bacteria will metabolize the urea and isotope labeled carbon dioxide will be released. The carbon dioxide is absorbed by the stomach tissue, passes into the blood where it travels to the lungs, and is excreted during respiration. Samples of exhaled breath are collected 10–15 minutes after the capsule has been ingested, and the presence of isotope labeled

carbon in the exhaled carbon dioxide is measured. If the isotope is present, *H. pylori* is present in the stomach. When the organism has been effectively treated with antibiotics, the test changes from positive to negative.

A stool antigen test may be used to identify the presence of *H. pylori*. This is an accurate test and may be requested for patients who are unable to cooperate for the urea breath test.

Examination of tissue biopsy, obtained by endoscopy, from the lining of the stomach is another way to identify the presence of *H. pylori*. The sample is tested for urease activity and is histologically examined for the presence of inflammatory epithelial cells in the presence of the characteristically curve shaped *H. pylori* bacteria.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in differentiating between *H. pylori* infection and NSAID use as the cause of gastritis or peptic or duodenal ulcer
- Assist in establishing a diagnosis of gastritis, gastric carcinoma, or peptic or duodenal ulcer

POTENTIAL DIAGNOSIS**Positive findings in**

- *H. pylori* infection
- *H. pylori* colonization

Negative findings in: N/A**CRITICAL FINDINGS:** N/A**INTERFERING FACTORS:** N/A**NURSING IMPLICATIONS AND PROCEDURE****Potential Nursing Problems:**

Problem	Signs & Symptoms	Interventions
Infection <i>(Related to fecal matter–contaminated food or water)</i>	Dark- or tar-colored stools; bloating; abdominal pain; feeling full after eating a small meal; lack of appetite; nausea and vomiting; development of stomach cancer	Administer prescribed proton pump inhibitors; administer prescribed antibiotics; avoid alcoholic beverages
Pain <i>(Related to gastric irritation; gastric inflammation)</i>	Abdominal cramping; abdominal distention; report of pain; emotional symptoms of distress; crying; agitation; facial grimace; moaning; verbalization of pain; irritability; disturbed sleep; altered blood pressure and heart rate; nausea; vomiting	Collaborate with the patient and physician to identify the best pain management modality to provide relief; refrain from activities that may aggravate pain; monitor pain severity; administer prescribed proton pump inhibitors; administer prescribed antibiotics; administer H ₂ receptor antagonists; administer prescribed antacids
Nutrition <i>(Related to nausea and vomiting; alcohol use; diarrhea; gastrointestinal bleed; abdominal pain)</i>	Known inadequate caloric intake; weight loss; muscle wasting in arms and legs; skin that is flaky with loss of elasticity; inadequate absorption of iron, vitamins, and minerals	Document food intake with possible calorie count; assess barriers to eating; consider using a food diary; monitor daily weight; arrange dietary consult with assessment of cultural food selections; encourage limitation of coffee and other caffeinated beverages; discuss refraining from excessive alcohol use
Fatigue <i>(Related to bleeding; pain; inadequate nutrition;</i>	Decreased concentration; increased physical complaints; inability to restore energy with	Assess for physical cause of fatigue; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over

Problem	Signs & Symptoms	Interventions
nausea; vomiting)	sleep; reports being tired; inability to maintain normal routine; decreasing HGB/HCT; nausea; vomiting; inadequate dietary intake; self-report of abdominal pain	time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia; monitor for black tarry stools that are indicative of bleeding; administer prescribed blood or blood products; administer prescribed antiemetic and antidiarrheal medication; monitor and trend HGB/HCT

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ Inform the patient that the test is used to assist in the diagnosis of *H. pylori* infection in patients with duodenal and gastric disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Assess for chronic use of medications known to irritate gastrointestinal (GI) tract. Information should also be collected regarding diet, use of alcohol, use of tobacco products, and any relationship between GI symptoms and timing of meals, medications, or ingestion of coffee or alcohol. Assess the patient's level of emotional stress and inquire about factors that trigger feelings of anxiety or stress.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to

10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Provide education regarding the disease, factors that can trigger symptoms, and possible treatment options that may include surgery.
- ▶ Stress the importance of adhering to requests for follow-up visits as ordered.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Inform the patient that a positive test result constitutes an independent risk factor for gastric cancer.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:**Knowledge**

- ▶ States the importance of taking prescribed antibiotics until completed to ensure infection is resolved
- ▶ States the importance of taking prescribed medications to manage infection and decrease pain

Skills

- ▶ Demonstrates proficient use of guided imagery and relaxation techniques to assist with pain management
- ▶ Identifies foods that cause gastric distress and develops a plan to avoid those foods

Attitude

- ▶ Complies with the request to abstain from excessive alcohol use
- ▶ Complies with the request to refrain from eating foods that cause gastric irritation

RELATED MONOGRAPHS:

- ▶ Related tests include capsule endoscopy, EGD, gastric acid stimulation, gastric emptying scan, gastrin, and upper GI series.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related test by body system.

Hemoglobin Electrophoresis

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in evaluating hemolytic anemias and identifying hemoglobin variants, diagnose thalassemias, and sickle cell anemia.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Electrophoresis)

	Hgb A
Adult	Greater than 95%
	Hgb A₂
Adult	1.5–3.7%
	Hgb F
Newborns and infants	
1 day–3 wk	70–77%
6–9 wk	42–64%
3–4 mo	7–39%
6 mo	3–7%
8–11 mo	0.6–2.6%
Adult–older adult	Less than 2%

DESCRIPTION: Hemoglobin (Hgb) electrophoresis is a separation process used to identify normal and abnormal forms of Hgb. Electrophoresis and high-performance liquid chromatography as well as molecular genetics testing for mutations can also be used to identify abnormal forms of Hgb. Hgb A is the main form of Hgb in the normal adult. Hgb F is the main form of Hgb in the fetus, the remainder being composed of Hgb A₁ and A₂. Small amounts of Hgb F are normal in the adult. Hgb D, E, H, S, and C result from abnormal amino acid substitutions during the formation of Hgb and are inherited hemoglobinopathies.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of Hgb C disease
- Assist in the diagnosis of thalassemia, especially in patients with a family history positive for the disorder
- Differentiate among thalassemia types
- Evaluate hemolytic anemia of unknown cause

- Evaluate a positive sickle cell screening test to differentiate sickle cell trait from sickle cell disease

POTENTIAL DIAGNOSIS

Increased in

Hgb A₂

- Hyperthyroidism
- Megaloblastic anemia
- β -Thalassemias
- Sickle trait

Hgb F

- Anemia (aplastic, associated with chronic disease or due to blood loss)
- Erythropoietic porphyria
- Hereditary elliptocytosis or spherocytosis
- Hereditary persistence of fetal Hgb
- Hyperthyroidism
- Leakage of fetal blood into maternal circulation
- Leukemia (acute or chronic)
- Myeloproliferative disorders
- Paroxysmal nocturnal hemoglobinuria
- Pernicious anemia
- Sickle cell disease
- Thalassemias
- Unstable hemoglobins

Hgb C

- Hgb C disease (second most common variant in the United States; has a higher prevalence among African Americans)

Hgb D

- Hgb D (rare hemoglobinopathy that may also be found in combination with Hgb S or thalassemia)

Hgb E

- Hgb E disease; thalassemia-like condition (second most common hemoglobinopathy in the world; occurs with the highest frequency in Southeast Asians and African Americans)

Hgb S

- Sickle cell trait or disease (most common variant in the United States; occurs with a frequency of about 8% among African Americans)

Hgb H

- α -Thalassemias
- Hgb Bart's hydrops fetalis syndrome

Decreased in**Hgb A₂**

- Erythroleukemia
- Hgb H disease
- Iron-deficiency anemia (untreated)
- Sideroblastic anemia

CRITICAL FINDINGS: N/A**INTERFERING FACTORS**

- High altitude *related to a compensatory mechanism whereby red blood cell (RBC) production is increased to increase availability of oxygen binding to Hgb* and dehydration *related to hemoconcentration* may increase values.
- Iron deficiency may decrease Hgb A₂, C, and S *related to decreased amounts of Hgb in smaller, iron-deficient RBCs.*
- In patients less than 3 mo of age, false-negative results for Hgb S occur in coincidental polycythemia *related to technical limitations of the procedure where increased total Hgb levels reflect a small, possibly undetectable percentage of Hgb S when compared to large amounts of Hgb F.*
- Red blood cell transfusion within 4 mo of test can mask abnormal Hgb levels.

NURSING IMPLICATIONS AND PROCEDURE**Potential Nursing Problems:**

Problem	Signs & Symptoms	Interventions
Health management (<i>Related to excessive demands; support deficit; conflicted decision making; limited resources; sense of powerlessness</i>)	Inability or failure to recognize or process information toward improving health and preventing illness with associated mental and physical effects	Assess health habits to obtain an interventional baseline; obtain a current health history; identify the patient's and family's learning styles; refrain from using medical jargon; observe for altered literacy cues; provide most important information first and reinforce with additional education; ensure the patient understands the ramifications of a lack of healthy behaviors on

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to hypoxic vaso-occlusive crisis secondary to sickling disease</i>)	Emotional symptoms of distress; crying; agitation; facial grimace; moaning; verbalization of pain; rocking motions; irritability; disturbed sleep; diaphoresis; altered blood pressure and heart rate; nausea; vomiting; self-report of pain; limited mobility	sickling events; identify number of emergency department visits for sickling crises; instruct the patient and family on situations that can precipitate a crisis; recommend genetic counseling Collaborate with the patient and physician to identify the best pain management modality to provide relief; refrain from activities that may aggravate pain; use the application of heat or cold to the best effect in managing the pain; monitor pain severity; assess sickle pain characteristics, location, type, and duration; monitor pain severity (severe joint pain, abdominal, or back pain may last for days); administer prescribed pain medication (typically IV morphine, hydromorphone, or fentanyl, NSAIDs); monitor HGB/HCT and transfuse with blood as ordered; use splinting of joints, joint support, moist heat to manage pain; consider distraction and rest periods
Coping (<i>Related to sense of powerlessness secondary to sickling event; feeling loss of control; poor</i>)	Anxiety; demonstrated inability to cope; poor problem solving; inability to meet role expectations; fatigue; frequent illness; poor goal-directed behavior;	Assess the ability to convey feelings clearly and appropriately; assess presence and stability of support structure; evaluate number of emergency

(table continues on page 902)

Problem	Signs & Symptoms	Interventions
<i>support system; chronic nature of the disease process)</i>	fear; difficulty asking for help	department visits with sickling events; discuss concerns with the patient at a time that the pain is controlled; provide education related to the treatment of and chronic nature of the disease; consult with social services and case management for home support and community resources
Mobility (<i>Related to pain hypoxic vaso-occlusive crisis secondary to sickling disease)</i>	Difficulty in the performance of purposeful movement (walking, turning, transfers); pain with movement; reluctance or refusal to move; inability to perform directed movement	Assess baseline ability to move; assess need for assistive devices, encourage appropriate use; assess pain level; assess pain medication effectiveness; administer prescribed pain medication; assess emotional response to mobility deficits; ensure a safe environment with side rail up; ensure that room is not cluttered; facilitate ambulation as appropriate; monitor for skin breakdown and deep vein thrombosis (DVT)

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing various types of anemias.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological

support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Teach the patient that the frequency of sickling crises is reflective of disease control and need for review of therapeutic management.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach patient and family the pathophysiology of sickle cell disease in understandable terms.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that the support of similar patients may assist with coping and disease management
- ▶ States understanding that adherence to disease management recommendations can decrease sickling events

Skills

- ▶ Describes lifestyle changes that can be made to decrease hypoxic episodes and the incidence of sickling crises
- ▶ Identifies symptoms of infection that should be reported to the HCP

Attitude

- ▶ Complies with the request for genetic counseling
- ▶ Complies with recommended therapeutic management for sickle cell disease

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, blood gases, CBC, CBC hematocrit, CBC hemoglobin, CBC RBC morphology, methemoglobin, newborn screening, osmotic fragility, and sickle cell screen.
- ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Hemosiderin

SYNONYM/ACRONYM: Hemosiderin stain, Pappenheimer body stain, iron stain.

COMMON USE: To assist in investigating recent intravascular hemolysis and to assist in the diagnosis of unexplained anemias, hemochromatosis, and renal tube damage.

SPECIMEN: Urine (5 mL) from a random first morning sample, collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Microscopic examination of Prussian blue-stained specimen) None seen.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Any condition that involves hemolysis will release hemoglobin from RBCs into circulation. Hemoglobin is converted to hemosiderin in the renal tubular epithelial cells.

- Burns
- Cold hemagglutinin disease
- Hemochromatosis

- Hemolytic transfusion reactions
- Mechanical trauma to RBCs
- Megaloblastic anemia
- Microangiopathic hemolytic anemia
- Paroxysmal nocturnal hemoglobinuria
- Pernicious anemia
- Sickle cell anemia
- Thalassemia major

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Hepatitis A Antibody

SYNONYM/ACRONYM: HAV serology.

COMMON USE: To test blood for the presence of antibodies that would indicate a past or current hepatitis A infection.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Enzyme immunoassay) Negative.

DESCRIPTION: The hepatitis A virus (HAV) is classified as a picornavirus. Its primary mode of transmission is by the fecal-oral route under conditions of poor personal hygiene or inadequate sanitation. The incubation period is about 28 days, with a range of 15 to 50 days. Onset is usually abrupt, with the acute disease lasting about 1 wk. Therapy is supportive, and there is no development of chronic or carrier states. Assays for total (immunoglobulin G and immunoglobulin M [IgM]) hepatitis A antibody and IgM-specific hepatitis A antibody assist in differentiating recent infection from prior exposure. If results from the IgM-specific or from both assays are positive, recent infection is suspected. If the IgM-specific test results are negative and the total antibody test results are positive, past infection is indicated. The clinically significant assay—IgM-specific antibody—is

often the only test requested. Jaundice occurs in 70% to 80% of adult cases of HAV infection and in 70% of pediatric cases.

This procedure is contraindicated for: N/A

INDICATIONS

- Screen individuals at high risk of exposure, such as those in long-term residential facilities or correctional facilities
- Screen individuals with suspected HAV infection

POTENTIAL DIAGNOSIS

Positive findings in

- Individuals with current HAV infection
- Individuals with past HAV infection

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fatigue (<i>Related to decreased energy secondary to liver dysfunction associated with disease process and resulting inadequate absorption, metabolism and storage of nutrients</i>)	Decreased concentration; increased physical complaints; inability to restore energy with sleep; reports being tired; inability to maintain normal routine	Assess for physical cause of fatigue; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia

(table continues on page 906)

Problem	Signs & Symptoms	Interventions
Knowledge <i>(Related to new condition or diagnosis; lack of familiarity or understanding with disease and treatment)</i>	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management	Teach the patient that the disease is transmitted by fecal-oral route, crowded living conditions, poor personal hygiene, contaminated water, contaminated food, contaminated milk, and raw shellfish; assess patient's and family's knowledge regarding disease, transmission, and treatment; assess for cultural, literacy, or vision and hearing concerns that would interfere with learning; explain that adequate nutrition and rest can prevent disease complications; demonstrate proper hand-washing technique with re-demonstration; emphasize vigilant hand washing; explain that crowded living conditions and poor sanitation should be avoided; encourage family members to receive hepatitis vaccine; make patients aware that sexual partners should receive the hepatitis vaccine
Infection <i>(Related to crowded living conditions with poor sanitation; poor personal hygiene; fecal-oral exposure; exposure to contaminated water, milk, food; raw shellfish)</i>	Fever; fatigue; loss of appetite; jaundice; nausea and vomiting; dark-colored urine; abdominal pain; stool that is clay colored; joint pain; it is possible to be infected and have no symptoms	Explain that the best treatment is adequate rest, good nutrition, and adequate fluid intake; recommend that family and significant others receive the hepatitis vaccination; explain that alcohol should be avoided to decrease risk of liver damage; explain that over-the-counter medication should be checked with the physician before taking to ensure there is no risk to the liver; explain that jaundice can last several months

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating for hepatitis infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hepatobiliary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Dietary recommendations may be indicated and will vary depending on the type and severity of the condition. Elimination of alcohol ingestion and a diet optimized for convalescence are commonly included in the treatment plan. Explain the importance of providing an adequate daily fluid intake of at least 4 L. Monitor the patient's weight, intake, and output each day and assess for development of ascites. Elimination of alcohol ingestion and a diet optimized for convalescence are commonly included in the treatment plan. As a general rule, small, frequent meals that are high in carbohydrates and low in fat will provide the required energy while not burdening the inflamed liver.
- ▶ **Social and Cultural Considerations:** Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis. Stress the importance of hand hygiene to prevent transmission of the virus. Immune globulin can be given before exposure (in the case of individuals who may be traveling to a location where the disease is endemic) or after exposure, during the incubation period. Prophylaxis is most effective when administered 2 wk after exposure.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

- ▶ Provide information regarding vaccine-preventable diseases where indicated (e.g., hepatitis A).
- ▶ Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac) and (www.cdc.gov/DiseasesConditions).
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States the importance of washing hands after using the bathroom and prior to food preparation
- ▶ States understanding that this disease is spread by contact with infected fecal matter

Skills

- ▶ Demonstrates proficient hand washing
- ▶ Grasps the importance of using protective personal equipment, such as gloves if necessary, to prevent disease transmission

Attitude

- ▶ Complies with the request to avoid drinking untreated water
- ▶ Complies with the request to avoid washing food in untreated water

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, ALP, AST, bilirubin, GGT, and HBV, HBC, HBD, and HBE antigens and antibodies.
- ▶ Refer to the Hepatobiliary and Immune systems tables at the end of the book for related tests by body system.

Hepatitis B Antigen and Antibody

SYNONYM/ACRONYM: HBeAg, HBeAb, HBcAb, HBsAb, HBsAg.

COMMON USE: To test blood for the presence of antibodies that would indicate a past or current hepatitis B infection.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Enzyme immunoassay) Negative.

DESCRIPTION: The hepatitis B virus (HBV) is classified as a double-stranded DNA retrovirus of the Hepadnaviridae family. Its primary modes of transmission are parenteral, perinatal, and sexual contact. Serological profiles vary with different scenarios (i.e., asymptomatic infection, acute/resolved infection, coinfection, and chronic carrier state). The formation and detectability of markers is also dose dependent. The following

description refers to HBV infection that becomes resolved. The incubation period is generally 6 to 16 wk. The hepatitis B surface antigen (HBsAg) is the first marker to appear after infection. It is detectable 8 to 12 wk after exposure and often precedes symptoms. At about the time liver enzymes fall back to normal levels, the HBsAg titer has fallen to nondetectable levels. If the HBsAg remains detectable after 6 mo, the

patient will likely become a chronic carrier who can transmit the virus. Hepatitis Be antigen (HBeAg) appears in the serum 10 to 12 wk after exposure. HBeAg can be found in the serum of patients with acute or chronic HBV infection and is a sign of active viral replication and infectivity. Levels of hepatitis Be antibody (HBeAb) appear about 14 wk after exposure, suggesting resolution of the infection and reduction of the patient's ability to transmit the disease. The more quickly HBeAg disappears, the shorter the acute phase of the infection. Immunoglobulin M-specific hepatitis B core antibody (HBcAb) appears 6 to 14 wk after exposure to HBsAg and continues to be detectable either until the infection is resolved or over the life span in patients who are in a chronic carrier state. In some cases, HBcAb may be the only detectable marker; hence, its lone appearance has sometimes been referred to as the *core window*. HBcAb is not an indicator of recovery or immunity; however, it does indicate current or previous infection. Hepatitis B surface antibody (HBsAb) appears 2 to 16 wk after HBsAg disappears. Appearance of HBsAb represents clinical recovery and immunity to the virus.

Onset of HBV infection is usually insidious. Most children and half of infected adults are asymptomatic. During the acute phase of infection, symptoms range from mild to severe. Chronicity decreases with age. HBsAg and HBcAb tests are used to screen

donated blood before transfusion. HBsAg testing is often part of the routine prenatal screen. Vaccination of infants, children, and young adults is becoming a standard of care and in some cases a requirement.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect exposure to HBV
- Detect possible carrier status
- Pre- and postvaccination testing
- Routine prenatal testing
- Screen donated blood before transfusion
- Screen for individuals at high risk of exposure, such as hemodialysis patients, persons with multiple sex partners, persons with a history of other sexually transmitted diseases, IV drug abusers, infants born to infected mothers, individuals residing in long-term residential facilities or correctional facilities, recipients of blood- or plasma-derived products, allied health-care workers, and public service employees who come in contact with blood and blood products

POTENTIAL DIAGNOSIS

Positive findings in

- Patients currently infected with HBV
- Patients with a past HBV infection

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may decrease HBeAb and HBsAb include interferon.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fatigue <i>(Related to decreased energy secondary to liver dysfunction associated with disease process and resulting inadequate absorption, metabolism and storage of nutrients)</i>	Decreased concentration; increased physical complaints; unable to restore energy with sleep; reports being tired; unable to maintain normal routine	Assess for physical cause of fatigue; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia
Knowledge <i>(Related to new condition or diagnosis; lack of familiarity or understanding with disease and treatment)</i>	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management	Teach the process of disease transmission, sharing needles with infected persons, unprotected sex with an infected person, sharing blood or body fluid with an infected person, blood products from an infected person; assess the patient and family knowledge of disease, transmission, and treatment; assess for cultural, literacy, or vision and hearing concerns that would interfere with learning; explain that adequate nutrition and rest can prevent disease complications; demonstrate proper hand-washing technique with re-demonstration; emphasize vigilant hand washing; discuss the implications of the disease as related to future blood donations (not possible);

Problem	Signs & Symptoms	Interventions
Infection (Related to unprotected sex; exposure to blood and body fluids of an infected person; sharing needles with an infected person)	Fever; fatigue; loss of appetite; jaundice; nausea and vomiting; dark-colored urine; abdominal pain; stool that is clay colored; joint pain; it is possible there will be no symptoms	<p>discuss safe sex; explain that razors, toothbrushes, and other personal care items should not be shared; encourage family member to receive hepatitis vaccine; make patients aware that sexual partners should receive the hepatitis vaccine; explain that infected pregnant women can pass the disease to the child at birth</p> <p>Explain that the best treatment is adequate rest, good nutrition, and adequate fluid intake; recommend that family and significant others receive the hepatitis vaccination; explain that alcohol should be avoided to decrease risk of liver damage; explain that over-the-counter medication should be checked with the physician before taking to ensure there is no risk to the liver; explain that jaundice can last several months; administer prescribed medications</p>
Activity (Related to inadequate nutrient metabolism; increased basal metabolic rate associated with viral infection)	Verbal report of weakness; inability to tolerate activity; shortness of breath with activity; altered heart rate, blood pressure, and respiratory rate with activity	Assess current level of physical activity; take baseline vital signs; trend vital signs with activity; assess response to activity; monitor for oxygen desaturation with activity; administer prescribed oxygen with activity; collaborate with physical therapy to support activity; monitor blood pressure for orthostatic changes; collaborate with the patient to establish activity goals and guidelines; pace activities to match energy stores; assist with self-care;

(table continues on page 912)

Problem

Signs & Symptoms

Interventions

monitor liver enzyme levels; encourage long, uninterrupted periods of rest; consider use of bedside commode; assist patient in setting realistic activity goals

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating for hepatitis infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hepatobiliary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a history of IV drug use, high-risk sexual activity, or occupational exposure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the

patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Dietary recommendations may be indicated and will vary depending on the type and severity of the condition. Explain the importance of providing an adequate daily fluid intake of at least 4 L. Monitor the patient's weight, intake, and output each day, and assess for development of ascites. Elimination of alcohol ingestion and a diet optimized for convalescence are commonly included in the treatment plan. As a general rule, small frequent meals that are high in carbohydrates and low in fat will provide the required energy while not burdening the inflamed liver.
- ▶ **Cultural and Social Considerations:** Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and

fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis. Stress the importance of hand hygiene to prevent transmission of the virus. Hepatitis B immune globulin (HBIG) vaccination should be given immediately after situations in which there is a potential for HBV exposure (e.g., accidental needle stick, perinatal period, sexual contact) for temporary, passive protection. Some studies have indicated that interferon alfa may be useful in the treatment of chronic hepatitis B.

- ▶ Counsel the patient and significant contacts, as appropriate, that HBIG immunization is available and has in fact become a requirement in many places as part of childhood immunization and employee health programs. Parents may choose to sign a waiver preventing their newborns from receiving the vaccine; they may choose not to vaccinate on the basis of philosophical, religious, or medical reasons. Vaccination regulations vary by state.

- ▶ Inform the patient that positive findings must be reported to local health department officials, who will question him or her regarding sexual partners.

- ▶ **Cultural and Social Considerations:** Offer support, as appropriate, to patients who may be the victims of rape or other forms of sexual assault, including children and elderly individuals.

Educate the patient regarding access to counseling services. Provide a non-judgmental, nonthreatening atmosphere for a discussion during which the risks of sexually transmitted diseases are explained. It is also important to discuss the problems that the patient may experience (e.g., guilt, depression, anger).

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation

to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Provide information regarding vaccine-preventable diseases where indicated (e.g., hepatitis B).
- ▶ Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac) and (www.cdc.gov/DiseasesConditions).
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States the importance of family members and sexual partners receiving hepatitis vaccine to protect against infection
- ▶ States the importance of using family or significant other to use personal protective equipment such as gloves to protect from infection and use good hand washing practices

Skills

- ▶ Family and significant other demonstrate the proper technique in the application and removal of gloves as personal protective equipment and hand washing
- ▶ Relates the importance of hepatitis vaccine immunization to family members and significant others, as well as sexual partners

Attitude

- ▶ Complies with the request to abstain from alcohol use
- ▶ Complies with the request to rest prior to meals to increase appetite and calorie intake

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, ALP, antibodies, antimitochondrial, AST, bilirubin, biopsy liver, *Chlamydia* group antibody, cholangiography percutaneous transhepatic, culture anal, GGT, hepatitis C serology, HIV serology, liver and spleen scan, syphilis serology, and US liver.
- ▶ Refer to the Hepatobiliary and Immune systems tables at the end of the book for related tests by body system.

Hepatitis C Antibody

SYNONYM/ACRONYM: HCV serology, hepatitis non-A/non-B.

COMMON USE: To test blood for the presence of antibodies that would indicate a past or current hepatitis C infection.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Enzyme immunoassay, branched chain DNA [bDNA], polymerase chain reaction [PCR], recombinant immunoblot assay [RIBA]) Negative.

DESCRIPTION: The hepatitis C virus (HCV) causes the majority of bloodborne non-A/non-B hepatitis cases. Its primary modes of transmission are parenteral, perinatal, and sexual contact. The virus is thought to be a flavivirus and contains a single-stranded RNA core. The incubation period varies widely, from 2 to 52 wk. Onset is insidious, and the risk of chronic liver disease after infection is high. On average, antibodies to hepatitis C are detectable in approximately 45% of infected individuals within 6 wk of infection. The remaining 55% produce antibodies within the next 6 to 12 mo. Once infected with HCV, 50% of patients will become chronic carriers. Infected individuals and carriers have a high frequency of chronic liver diseases such as cirrhosis and chronic active hepatitis, and they have a higher risk of developing hepatocellular cancer. The transmission of hepatitis C by blood transfusion has decreased dramatically since it became part of the routine screening panel for blood donors. The possibility of prenatal transmission exists, especially in the presence of HIV coinfection. Therefore, this test is often

included in prenatal testing packages. Currently, nucleic acid amplification testing (NAAT) is the only way to document the presence of ongoing infection. PCR and bDNA methods are recognized by the Centers for Disease Control and Prevention (CDC) as appropriate supplemental testing for the confirmation of anti-HCV antibody.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of non-A/non-B viral hepatitis infection
- Monitor patients suspected of HCV infection but who have not yet produced antibody
- Routine prenatal testing
- Screen donated blood before transfusion

POTENTIAL DIAGNOSIS

Positive findings in

- Patients currently infected with HCV
- Patients with a past HCV infection

Negative findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may decrease hepatitis C antibody levels include interferon.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Knowledge <i>(Related to new condition or diagnosis; lack of familiarity or understanding with disease and treatment)</i>	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management	Teach the process of disease transmission, sharing needles with infected persons, unprotected sex with an infected person, sharing blood or body fluid with an infected person, blood products from an infected person; assess the patient's and family's knowledge of the disease, transmission, and treatment; assess for cultural, literacy, or vision and hearing concerns that would interfere with learning; explain that adequate nutrition and rest can prevent disease complications; demonstrate proper hand-washing technique with re-demonstration; emphasize vigilant hand washing; discuss the implications of the disease as related to future blood donations (not possible); discuss safe sex; explain that razors, toothbrushes, and other personal care items should not be shared
Infection <i>(Related to unprotected sex; exposure to blood and body fluids of an infected person; sharing needles with an infected person)</i>	Fever; fatigue; loss of appetite; jaundice; nausea and vomiting; dark-colored urine; abdominal pain; stool that is clay colored; joint pain; there may be no symptoms with chronic disease	Explain that the best treatment is adequate rest, good nutrition, and adequate fluid intake; administer prescribed interferon and ribavirin for chronic hepatitis

(table continues on page 916)

Problem	Signs & Symptoms	Interventions
Fatigue (<i>Related to decreased energy secondary to liver dysfunction associated with disease process and resulting inadequate absorption, metabolism, and storage of nutrients</i>)	Decreased concentration; increased physical complaints; inability to restore energy with sleep; reports of being tired; inability to maintain normal routine	Assess for physical cause of fatigue; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia
Nutrition (<i>Related to the inability to adequately store or metabolize foods; lack of appetite; refusal to eat; nausea and vomiting</i>)	Unintended weight loss; pale dry skin; dry mucous membranes; documented inadequate caloric intake; subcutaneous tissue loss; hair pulls out easily; paresthesias	Record accurate daily weight at the same time each day with the same scale; obtain an accurate nutritional history; assess for nausea and administer prescribed medication; assess attitude toward eating; promote a dietary consult to evaluate current eating habits and best method of nutritional supplementation; develop short- and long-term eating strategies; monitor nutritional laboratory values such as albumin, transferrin, red blood cells (RBC), white blood cells (WBC), and serum electrolytes; encourage cultural home foods; provide a pleasant environment for eating; alter food seasoning to enhance flavor; provide parenteral or enteral nutrition as prescribed; encourage appropriate use of recommended vitamin supplements

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- Patient Teaching:** Inform the patient this test can assist in evaluating for hepatitis infection.
- Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's hepatobiliary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a history of IV drug use, high-risk sexual activity, and occupational exposure.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Dietary recommendations may be indicated and will vary depending on the type and severity of the condition. Explain the importance of providing an adequate daily fluid intake of at least 4 L. Monitor the patient's weight, intake, and output each day, and assess for development of ascites. Elimination of alcohol ingestion and a diet optimized for convalescence are commonly included in the treatment plan. As a general rule, small, frequent meals that are high in carbohydrates and low in fat will provide the required energy while not burdening the inflamed liver.
- ▶ **Cultural and Social Considerations:** Recognize anxiety related to test results, and be supportive of impaired activity related to lack of neuromuscular control, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Counsel the patient, as appropriate, regarding the risk of transmission and proper prophylaxis. Stress the importance of hand hygiene to prevent transmission of the virus. Interferon alfa was approved in 1991 by the U.S. Food and Drug Administration for use as a therapeutic agent in the treatment of chronic HCV infection.
- ▶ Inform the patient that positive findings must be reported to local health department officials, who will question him or her regarding sexual partners.
- ▶ **Cultural and Social Considerations:** Offer support, as appropriate, to patients who may be the victims of rape or other forms of sexual assault, including children and elderly individuals. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a

discussion during which the risks of sexually transmitted diseases are explained. It is also important to discuss the problems that the patient may experience (e.g., guilt, depression, anger).

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Provide contact information, if desired, for the CDC (www.cdc.gov/vaccines/vpd-vac) and (www.cdc.gov/DiseasesConditions).
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that this disease can lead to liver scarring and liver cancer.

- ▶ States understanding that this disease can last a lifetime and may result in liver transplant.

Skills

- ▶ Avoids situations where there can be exposure to infected blood
- ▶ Takes precautions to avoid infecting others

Attitude

- ▶ Accurately relates that it is possible that this disease may be present without significant symptoms
- ▶ Complies with recommendation to eat several small meals a day to support adequate nutrition

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, ALP, antibodies, antimitochondrial, AST, bilirubin, biopsy liver, Chlamydia group antibody, cholangiography percutaneous transhepatic, culture anal, GGT, hepatitis B serology, hepatobiliary scan, HIV serology, liver and spleen scan, syphilis serology, and US liver.
- ▶ Refer to the Hepatobiliary and Immune systems tables at the end of the book for related tests by body system.

Hepatitis D Antibody

SYNONYM/ACRONYM: Delta hepatitis.

COMMON USE: To test blood for the presence of antibodies that would indicate a past or current hepatitis D infections.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Enzyme immunoassay, EIA) Negative.

This procedure is contraindicated for: N/A

- Individuals with a past HDV infection

POTENTIAL DIAGNOSIS

Positive findings in

- Individuals currently infected with HDV

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

CRITICAL FINDINGS: N/A

Hepatitis E Antibody

SYNONYM/ACRONYM: HEV.

COMMON USE: To test blood for the presence of antibodies that would indicate a past or current hepatitis E infection.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 h of collection.

NORMAL FINDINGS: (Method: Enzyme immunoassay) Negative.

This procedure is contraindicated for: N/A

- Individuals with past HEV infection

POTENTIAL DIAGNOSIS

Positive findings in

- Individuals with current HEV infection

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

CRITICAL FINDINGS: N/A

Hepatobiliary Scan

SYNONYM/ACRONYM: Biliary tract radionuclide scan, cholescintigraphy, hepatobiliary imaging, hepatobiliary scintigraphy, gallbladder scan, HIDA (a technetium-99m diisopropyl analogue) scan.

COMMON USE: To visualize and assess the cystic and common bile ducts of the gall bladder toward diagnosing obstructions, stones, inflammation, and tumor.

AREA OF APPLICATION: Bile ducts.

CONTRAST: IV contrast medium (iminodiacetic acid compounds), usually combined with technetium-99m.

DESCRIPTION: The hepatobiliary scan is a nuclear medicine study of the hepatobiliary excretion system. It is primarily used to determine the patency of the cystic and common bile ducts, but it can also be used to determine overall hepatic function, gallbladder function, presence of gallstones (indirectly), and sphincter of Oddi dysfunction. Technetium (Tc-99m) HIDA (tribromoethyl, an iminodiacetic acid) is injected IV and excreted into the bile duct system. A gamma camera detects the radiation emitted from the injected contrast medium, and a representative image of the duct system is obtained. The results are correlated with other diagnostic studies, such as IV cholangiography, computed tomography (CT) scan of the gallbladder, and ultrasonography. Gallbladder emptying or ejection fraction can be determined by administering a fatty meal or cholecystikinin to the patient. This procedure can be used before and after surgery to determine the extent of bile reflux.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of acute and chronic cholecystitis

- Aid in the diagnosis of suspected gallbladder disorders, such as inflammation, perforation, or calculi
- Assess enterogastric reflux
- Assess obstructive jaundice when done in combination with radiography or ultrasonography
- Determine common duct obstruction caused by tumors or choledocholithiasis
- Evaluate biliary enteric bypass patency
- Postoperatively evaluate gastric surgical procedures and abdominal trauma

POTENTIAL DIAGNOSIS

Normal findings in

- Normal shape, size, and function of the gallbladder with patent cystic and common bile ducts

Abnormal findings in

- Cholecystitis (acalculous, acute, chronic)
- Common bile duct obstruction secondary to gallstones, tumor, or stricture
- Congenital biliary atresia or choledochal cyst
- Postoperative biliary leak, fistula, or obstruction
- Trauma-induced bile leak or cyst

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field,

which may inhibit organ visualization and cause unclear images.

- Bilirubin levels greater than or equal to 30 mg/dL, depending on the radionuclide used, indicate significant liver damage, which may decrease hepatic uptake.
- Other nuclear scans done within the previous 24 to 48 hr.
- Fasting for more than 24 hr before the procedure, total parenteral nutrition, and alcoholism.
- Ingestion of food or liquids within 2 to 4 hr before the scan.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue can produce erroneous hot spots.
- Inaccurate timing of imaging after the radionuclide injection can affect the results.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in detecting inflammation or obstruction of the gallbladder or ducts.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support

before, during, and after the procedure.

- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to restrict food and fluids for 4 to 6 hr prior to the procedure. Protocols may vary among facilities.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide.

Establishing an IV site and injection of radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; hematoma **related to blood leakage into the tissue following needle insertion**; infection **that might occur if bacteria from the skin surface is introduced at the puncture site**; or nerve injury **that might occur if the needle strikes a nerve**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluids, and medication restrictions for 4 to 6 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to radionuclides or medications.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie still during the procedure because movement produces unclear images.
- ▶ Administer sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- ▶ IV radionuclide is administered, and the upper right quadrant of the abdomen is scanned immediately, with images then taken every 5 min for the first 30 min and every 10 min for the next 30 min. If the gallbladder cannot be visualized, delayed views are taken in 2, 4, and 24 hr in order to differentiate acute from chronic cholecystitis or to detect the degree of obstruction.
- ▶ IV morphine may be administered during the study to initiate spasms of the sphincter of Oddi, forcing the radionuclide into the gallbladder, if the organ is not visualized within 1 hr of injection of the radionuclide. Imaging is then done 20 to 50 min later to determine delayed visualization or nonvisualization of the gallbladder.
- ▶ If gallbladder function or bile reflux is being assessed, the patient will be given a fatty meal or cholecystokinin 60 min after the injection.
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Unless contraindicated, advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity as directed by the HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing

- gloves. Then wash ungloved hands after the gloves are removed.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include amylase, bilirubin, CT abdomen, lipase, liver and spleen scan, MRI abdomen, radiofrequency ablation liver, US abdomen, and US liver and bile ducts.
- ▶ Refer to the Hepatobiliary System table at the end of the book for related tests by body system.

Hexosaminidase A and B

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing Tay-Sachs disease by identifying a hexosaminidase enzyme deficiency.

SPECIMEN: Serum (3 mL) collected in a red-top tube. After the specimen is collected, it must be brought immediately to the laboratory. Once in the laboratory, the specimen must be allowed to clot for 1 to 1.5 hr in the refrigerator. The serum should then be removed and frozen immediately.

NORMAL FINDINGS: (Method: Fluorometry)

Total Hexosaminidase	Conventional Units	SI Units (Conventional Units × 0.0167)
Noncarrier	589–955 nmol/hr/mL	9.83–15.95 units/L
Heterozygote	465–675 nmol/hr/mL	7.77–11.27 units/L
Tay-Sachs homozygote	Greater than 1,027 nmol/hr/mL	Greater than 17.15 units/L

Hexosaminidase A	Conventional Units	SI Units (Conventional Units × 0.0167)
Noncarrier	456–592 nmol/hr/mL	7.62–9.88 units/L
Heterozygote	197–323 nmol/hr/mL	3.29–5.39 units/L
Tay-Sachs homozygote	0 nmol/hr/mL	0 units/L

Hexosaminidase B	Conventional Units	SI Units (Conventional Units × 0.0167)
Noncarrier	12–32 nmol/hr/mL	0.2–0.54 units/L
Heterozygote	21–81 nmol/hr/mL	0.35–1.35 units/L
Tay-Sachs homozygote	Greater than 305 nmol/hr/mL	Greater than 5.09 units/L

This procedure is contraindicated for

- Parents who are not emotionally capable of understanding the test results and managing the ramifications of the test results.

POTENTIAL DIAGNOSIS

Increased in

Alterations in lysosomal enzymes metabolism are associated with various conditions.

- Total
 - Gastric cancer
 - Hepatic disease
 - Myeloma
 - Myocardial infarction
 - Pregnancy
 - Symptomatic porphyria
 - Vascular complications of diabetes

- Hexosaminidase A
 - Diabetes
 - Pregnancy
- Hexosaminidase B
 - Tay-Sachs disease

Decreased in

- Total
 - Sandhoff's disease (*inherited disorder of enzyme metabolism lacking both essential enzymes for metabolizing gangliosides*)
- Hexosaminidase A
 - Tay-Sachs disease (*inherited disorder of enzyme metabolism lacking only the hexosaminidase A enzyme for metabolizing gangliosides*)
- Hexosaminidase B
 - Sandhoff's disease

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Holter Monitor

SYNONYM/ACRONYM: Ambulatory electrocardiography, ambulatory monitoring, event recorder, Holter electrocardiography.

COMMON USE: To evaluate cardiac symptoms associated with activity to assist with diagnosis of arrhythmias and cardiomegaly.

AREA OF APPLICATION: Heart.

CONTRAST: None.

DESCRIPTION: The Holter monitor records electrical cardiac activity on a continuous basis for 24 to 72 hr. This noninvasive study includes the use of a portable device worn around the waist or over the shoulder that records cardiac electrical impulses on a magnetic tape. The recorder has a clock that allows accurate time markings on the tape and the patient is asked to keep a log or diary of daily activities and record any occurrence of cardiac symptoms. When the patient pushes a button indicating that symptoms (e.g., pain, palpitations, dyspnea, syncope) have occurred, an event marker is placed on the tape for later comparison with the cardiac activity recordings and the daily activity log. Some recorders allow the data to be transferred to the physician's office by telephone, where the tape is interpreted by a computer to detect any significantly abnormal variations in the recorded waveform patterns.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect arrhythmias that occur during normal daily activities and correlate them with symptoms experienced by the patient
- Evaluate activity intolerance related to oxygen supply and demand imbalance
- Evaluate chest pain, dizziness, syncope, and palpitations
- Evaluate the effectiveness of antiarrhythmic medications for dosage adjustment, if needed
- Evaluate pacemaker function
- Monitor for ischemia and arrhythmias after myocardial infarction or cardiac surgery before changing rehabilitation and other therapy regimens

POTENTIAL DIAGNOSIS

Normal findings in

- Normal sinus rhythm

Abnormal findings in

- Arrhythmias such as premature ventricular contractions, bradyarrhythmias, tachyarrhythmias, conduction defects, and bradycardia
- Cardiomyopathy
- Hypoxic or ischemic changes
- Mitral valve abnormality
- Palpitations

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Improper placement of the electrodes or movement of the electrodes.
- Failure of the patient to maintain a daily log of symptoms or to push the button to produce a mark on the strip when experiencing a symptom.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating the heart's response to exercise or medication.
- ▶ Obtain a history of the patient's complaints or symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain related to the procedure and explain that no electricity is delivered to the body during this procedure and no discomfort is experienced during monitoring. Inform the patient that the electrocardiography (ECG) recorder is worn for 24 to 48 hr, at which time the patient is to return to the laboratory with an activity log to have the monitor and strip removed for interpretation.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological

support before, during, and after the procedure.

- ▶ Instruct the patient to wear loose-fitting clothing over the electrodes and not to disturb or disconnect the electrodes or wires.
- ▶ Advise the patient to avoid contact with electrical devices that can affect the strip tracings (e.g., shavers, toothbrush, massager, blanket) and to avoid showers and tub bathing.
- ▶ Instruct the patient to perform normal activities, such as walking, sleeping, climbing stairs, sexual activity, bowel or urinary elimination, cigarette smoking, emotional upsets, and medications, and to record them in an activity log.
- ▶ Instruct the patient regarding recording and pressing the button upon experiencing pain or discomfort.
- ▶ Advise the patient to report a light signal on the monitor, which indicates equipment malfunction or that an electrode has come off.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Place the patient in a supine position.
- ▶ Expose the chest. Prepare the skin surface with alcohol and remove excess hair. Use clippers to remove hair from the site if appropriate; cleanse thoroughly with alcohol and rub until red in color.
- ▶ Apply electropaste to the skin sites to provide conduction between the skin and electrodes, or apply prelubricated disposable disk electrodes.
- ▶ Apply two electrodes (negative electrodes) on the manubrium, one in the V₁ position (fourth intercostal space at the border of the right sternum), and one at the V₅ position (level of the fifth

intercostal space at the midclavicular line, horizontally and at the left axillary line). A ground electrode is also placed and secured to the skin of the chest or abdomen.

- ▶ After checking to ensure that the electrodes are secure, attach the electrode cable to the monitor and the lead wires to the electrodes.
- ▶ Check the monitor for paper supply and battery, insert the tape, and turn on the recorder. Tape all wires to the chest, and place the belt or shoulder strap in the proper position.

POST-TEST:

- ▶ After the patient has worn the monitor for the required 24 to 48 hr, gently remove the tape and other items securing the electrodes to him or her.
- ▶ Compare the activity log and tape recording for changes during the monitoring period.
- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Advise the patient to immediately report symptoms such as fast heart rate or difficulty breathing.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of

independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antiarrhythmic drugs, blood pool imaging, calcium, chest x-ray, echocardiography, echocardiography transesophageal, electrocardiogram, exercise stress test, magnesium, myocardial perfusion heart scan, PET heart, and potassium.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Homocysteine and Methylmalonic Acid

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in evaluating increased risk for blood clots, plaque formation, and platelet aggregations associated with atherosclerosis and stroke risk.

SPECIMEN: Serum (4 mL) collected in a gold-, red-, or red/gray-top tube if methylmalonic acid and homocysteine are to be measured together. Alternatively, plasma collected in a lavender-top (EDTA) tube may be acceptable for the homocysteine measurement. The laboratory should be consulted before specimen collection because specimen type may be method dependent. Care must be taken to use the same type of collection container if serial measurements are to be taken.

NORMAL FINDINGS: (Method: Chromatography)

Conventional & SI Units

Homocysteine	4.6–11.2 micromol/L
Methylmalonic Acid	70–270 nmol/L

DESCRIPTION: Homocysteine is an amino acid formed from methionine. Normally, homocysteine is rapidly remethylated in a biochemical pathway that requires vitamin B₁₂ and folate, preventing the buildup of homocysteine in the blood.

Excess levels damage the endothelial lining of blood vessels; change coagulation factor levels, increasing the risk of blood clot formation and stroke; prevent smaller arteries from dilating, increasing the risk of plaque formation; cause platelet aggregation; and cause smooth muscle cells lining the arterial wall to multiply, promoting atherosclerosis.

Approximately one-third of patients with hyperhomocystinuria have normal fasting levels. Patients with a heterozygous biochemical enzyme defect in cystathionine B synthase or with a nutritional deficiency in vitamin B₆ can be identified through the administration of a methionine challenge or loading test.

Specimens are collected while fasting and 2 hr later. An increase in homocysteine after 2 hr is indicative of hyperhomocystinuria. In patients with vitamin B₁₂ deficiency, elevated levels of methylmalonic acid and homocysteine develop fairly early in the course of the disease. Unlike vitamin B₁₂ levels, homocysteine levels will remain elevated for at least 24 hr after the start of vitamin therapy. This may be useful if vitamin therapy is

inadvertently begun before specimen collection. Patients with folate deficiency, for the most part, will only develop elevated homocysteine levels. A methylmalonic acid level can differentiate between vitamin B₁₂ and folate deficiency, since it is increased in vitamin B₁₂ deficiency, but not in folate deficiency. Hyperhomocystinemia due to folate deficiency in pregnant women is believed to increase the risk of neural tube defects. Elevated levels of homocysteine are thought to chemically damage the exposed neural tissue of the developing fetus.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate inherited enzyme deficiencies that result in homocystinuria
- Evaluate the risk for cardiovascular disease
- Evaluate the risk for venous thrombosis

POTENTIAL DIAGNOSIS
Increased in

- Cerebrovascular disease (CVD) *(there is a relationship, but the pathophysiology is unclear)*
- Chronic renal failure *(pathophysiology is unclear)*
- Coronary artery disease (CAD) *(there is a relationship, but the pathophysiology is unclear)*
- Folic acid deficiency *(folate is required for completion of biochemical reactions involved in homocysteine metabolism)*
- Homocystinuria *(inherited disorder of methionine metabolism that results in accumulation of homocysteine)*
- Peripheral vascular disease *(related to vascular wall damage and*

formation of occlusive plaque)

- Vitamin B₁₂ deficiency (*vitamin B₁₂ is required for completion of biochemical reactions involved in homocysteine metabolism*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase plasma homocysteine levels include anticonvulsants, cycloserine, hydralazine, isoniazid, methotrexate, penicillamine, phenelzine, and procabazine.
- Drugs that may decrease plasma homocysteine levels include folic acid.
- Specimens should be kept at a refrigerated temperature and delivered immediately to the laboratory for processing.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in screening for risk of cardiovascular disease and stroke.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular and hematopoietic systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen

collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate collection container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture; collect the specimen for combined methylmalonic acid and homocysteine studies in two 5-mL red-, green-, or red/gray-top tubes. If only homocysteine is to be measured, a 5-mL lavender-top tube is acceptable.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased homocysteine levels may be associated with atherosclerosis and CAD. Nutritional therapy is recommended for

the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Nutritional Considerations:** Diets rich in fruits, grains, and cereals, in addition to a multivitamin containing B₁₂ and folate, may be recommended for patients with elevated homocysteine levels related to a dietary deficiency. Processed and refined foods should be kept to a minimum.

▶ **Nutritional Considerations:** Instruct the folate-deficient patient (especially pregnant women), as appropriate, to eat foods rich in folate, such as liver, salmon, eggs, asparagus, green leafy vegetables, broccoli, sweet potatoes, beans, and whole wheat.

▶ **Nutritional Considerations:** Instruct the patient with vitamin B₁₂ deficiency, as appropriate, in the use of vitamin supplements. Inform the patient, as appropriate, that the best dietary sources of vitamin B₁₂ are meats, fish, poultry, eggs, and milk.

▶ **Social and Cultural Considerations:** Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.

▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).

▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Educate the patient regarding access to nutritional counseling services. Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).

▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process

and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▶ Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BMD, BNP, BUN, calcitonin, calcium, cholesterol (total, HDL, and LDL), CBC, CBC RBC count, CBC RBC indices, CBC RBC morphology, CBC WBC count and

differential, CRP, CK and isoenzymes, creatinine, folate, glucose, glycosylated hemoglobin, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, myoglobin, osteocalcin, PTH, pericardial fluid analysis, potassium, prealbumin, renogram, triglycerides, troponin, US kidney, UA, and vitamin B₁₂.

▶ Refer to the Cardiovascular and Hematopoietic systems tables at the end of the book for related tests by body system.

Homovanillic Acid

SYNONYM/ACRONYM: HVA.

COMMON USE: To assist in diagnosis of neuroblastoma, pheochromocytoma, and ganglioblastoma and to monitor therapy.

SPECIMEN: Urine (10 mL) from a timed specimen collected in a clean plastic collection container with 6N HCl as a preservative.

NORMAL FINDINGS: (Method: Chromatography)

Age	Conventional Units	SI Units
<i>Homovanillic Acid</i>		(Conventional Units × 5.49)
3–6 yr	1.4–4.3 mg/24 hr	8–24 micromol/24 hr
7–10 yr	2.1–4.7 mg/24 hr	12–26 micromol/24 hr
11–16 yr	2.4–8.7 mg/24 hr	13–48 micromol/24 hr
Adult–older adult	1.4–8.8 mg/24 hr	8–48 micromol/24 hr
<i>Vanillylmandelic Acid</i>		(Conventional Units × 5.05)
3–6 yr	1–2.6 mg/24 hr	5–13 micromol/24 hr
7–10 yr	2–3.2 mg/24 hr	10–16 micromol/24 hr
11–16 yr	2.3–5.2 mg/24 hr	12–26 micromol/24 hr
Adult–older adult	1.4–6.5 mg/24 hr	7–33 micromol/24 hr

DESCRIPTION: Homovanillic acid (HVA) is the main terminal metabolite of dopamine. Vanillylmandelic acid is a major metabolite of epinephrine and norepinephrine.

Both of these tests should be evaluated together for the diagnosis of neuroblastoma. Excretion may be intermittent; therefore, a 24-hr specimen is preferred.

Creatinine is usually measured simultaneously to ensure adequate collection and to calculate an excretion ratio of metabolite to creatinine.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of pheochromocytoma, neuroblastoma, and ganglioblastoma
- Monitor the course of therapy

POTENTIAL DIAGNOSIS

Increased in
HVA is excreted in excessive amounts in the following conditions:

- Ganglioblastoma
- Neuroblastoma
- Pheochromocytoma
- Riley-Day syndrome

Decreased in

- Schizotypal personality disorders

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase HVA levels include acetylsalicylic acid, disulfiram, levodopa, pyridoxine, and reserpine.
- Drugs that may decrease HVA levels include moclobemide.
- All urine voided for the timed collection period must be included in the collection, or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in screening for presence of a tumor.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- ▶ Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- ▶ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ If possible, and with medical direction, patients should withhold acetylsalicylic acid, disulfiram, pyridoxine, and reserpine for 2 days before specimen collection. Levodopa should be withheld for 2 wk before specimen collection.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Ensure that the patient has complied with medication restrictions; assure that specified medications, with medical direction, have been restricted for at least 2 days prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

Timed Specimen

- ▶ Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- ▶ Begin the test between 6 and 8 a.m. if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger refrigerated container periodically during the collection

period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.

- ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- ▶ Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography adrenal, CEA, catecholamines, CT renal, metanephrines, renin, and VMA.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Human Chorionic Gonadotropin

SYNONYM/ACRONYM: Chorionic gonadotropin, pregnancy test, HCG, hCG, α -HCG, β -subunit HCG.

COMMON USE: To assist in verification of pregnancy, screen for neural tube defects, and evaluate human chorionic gonadotropin (HCG)-secreting tumors.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Immunoassay)

	Conventional Units	SI Units (Conventional Units \times 1)
Males and nonpregnant females	Less than 5 milli international units/mL	Less than 5 international units/L
Pregnant females by week of gestation:		
2 wk	5–100 milli international units/mL	5–100 international units/L
3 wk	200–3,000 milli international units/mL	200–3,000 international units/L
4 wk	10,000–80,000 milli international units/mL	10,000–80,000 international units/L
5–12 wk	90,000–500,000 milli international units/mL	90,000–500,000 international units/L
13–24 wk	5,000–80,000 milli international units/mL	5,000–80,000 international units/L
26–28 wk	3,000–15,000 milli international units/mL	3,000–15,000 international units/L

DESCRIPTION: Human chorionic gonadotropin (HCG) is a hormone secreted by the placenta beginning 8 to 10 days after conception, which coincides with implantation of the fertilized ovum. It stimulates secretion of progesterone by the corpus luteum. HCG levels peak at 8 to 12 wk of gestation and then fall to less than 10% of first trimester levels by the end of pregnancy. By postpartum

week 2, levels are undetectable. HCG levels increase at a slower rate in ectopic pregnancy and spontaneous abortion than in normal pregnancy; a low rate of change between serial specimens is predictive of a nonviable fetus. As assays improve in sensitivity over time, ectopic pregnancies are increasingly being identified before rupture. HCG is used along with α -fetoprotein, dimeric

inhibin-A, and estriol in prenatal screening for neural tube defects. These prenatal measurements are also known as *triple* or *quad markers*, depending on which tests are included. Serial measurements are needed for an accurate estimate of gestational stage and determination of fetal viability. Triple- and quad-marker testing has also been used to screen for trisomy 21 (Down syndrome). (To compare HCG to other tests in the triple- and quad-marker screening procedure, see monograph titled “ α_1 -Fetoprotein.”) HCG is also produced by some germ cell tumors. Most assays measure both the intact and free β -HCG subunit, but if HCG is to be used as a tumor marker, the assay must be capable of detecting both intact and free β -HCG.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of suspected HCG-producing tumors, such as choriocarcinoma, germ cell tumors of the ovary and testes, or hydatidiform moles
- Confirm pregnancy, assist in the diagnosis of suspected ectopic pregnancy, or determine threatened or incomplete abortion
- Determine adequacy of hormonal levels to maintain pregnancy
- Monitor effects of surgery or chemotherapy
- Monitor ovulation induction treatment
- Prenatally detect neural tube defects and trisomy 21 (Down syndrome)

POTENTIAL DIAGNOSIS

Increased in

- Choriocarcinoma (*related to HCG-producing tumor*)
- Ectopic HCG-producing tumors (stomach, lung, colon, pancreas, liver, breast) (*related to HCG-producing tumor*)
- Erythroblastosis fetalis (*bemolytic anemia as a result of fetal sensitization by incompatible maternal blood group antigens such as Rh, Kell, Kidd, and Duffy is associated with increased HCG levels*)
- Germ cell tumors (ovary and testes) (*related to HCG-producing tumors*)
- Hydatidiform mole (*related to HCG-secreting mole*)
- Islet cell tumors (*related to HCG-producing tumors*)
- Multiple gestation pregnancy (*related to increased levels produced by the presence of multiple fetuses*)
- Pregnancy (*related to increased production by placenta*)

Decreased in

Any condition associated with diminished viability of the placenta will reflect decreased levels.

- Ectopic pregnancy (*HCG levels increase slower than in viable intrauterine pregnancies, plateau, and then decrease prior to rupture*)
- Incomplete abortion
- Intrauterine fetal demise
- Spontaneous abortion
- Threatened abortion

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may decrease HCG levels include epostane and mifepristone.

- Results may vary widely depending on the sensitivity and specificity of the assay. Performance of the test too early in pregnancy may cause false-negative results. HCG is composed of an α and a β subunit. The structure of the α subunit is essentially identical to the β subunit of

follicle-stimulating hormone, luteinizing hormone, and thyroid-stimulating hormone. The structure of the β subunit differentiates HCG from the other hormones. False-positive results can therefore be obtained if the HCG assay does not detect β subunit.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Spirituality <i>(Related to potential or actual; fear of fetal death; loss of potential child)</i>	Forgiveness; acceptance; anger at spiritual leaders; expressed feelings of hopeless, powerlessness; abandonment; refusals or inability to participate in spiritual activities (prayer); expresses feelings over lack of meaning with life or serenity	Encourage the verbalization of feelings in a safe, nonjudgmental environment; assess the desire for contact from associated spiritual leader; foster a supportive relationship with the patient and family; encourage a display of objects (spiritual, religious) that provide emotional relief; assess for expressions of hope
Fear <i>(Related to possible loss of potential child; ineffective coping; unfamiliar therapeutic regime; unknown)</i>	Expression of fear; preoccupation with fear; increased tension; increased blood pressure; increased heart rate; vomiting; diarrhea; nausea; fatigue; weakness; insomnia; shortness of breath; increased respiratory rate; withdrawal; panic attacks	Provide specific education related to pregnancy confirmation and identification of viability; provide specific information related to ongoing pregnancy; communicate with social services for needed support; ensure education is culturally appropriate; assist the patient and family to recognize effective coping strategies; assist the patient and family to acknowledge their fear; provide a safe environment to discuss fear; explore cultural influences that may enhance fear; utilize therapeutic touch as appropriate to decrease fear
Family process <i>(Related to failure to maintain a</i>	Stated feelings of failing to provide children; change in communication	Offer family counseling; facilitate opportunities for the patient and spouse to express their

Problem	Signs & Symptoms	Interventions
viable pregnancy)	patterns between partners regarding having children; alterations in intimacy	feelings and their perception of the problem; evaluate patient and family weaknesses, strengths, and coping strategies; help the family and patient break down concerns into manageable parts
Grief (Related to fetal loss; inability to carry child to term)	Apparent psychological and emotional distress; withdrawal; detachment; loss of appetite; refusal to participate in activities of daily living; anger; blame	Assess decision-making ability; encourage expression of grief; provide contact information for grief support group; assist to identify current support group; provide social services referral as appropriate; allow the patient and spouse to relieve the loss and express feelings

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in screening for pregnancy, identifying tumors, and evaluating fetal health.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine, immune, and reproductive systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP),

who will discuss the results with the patient.

▶ **Social and Cultural Considerations:**

Recognize anxiety related to abnormal test results, and encourage the family to seek counseling if concerned with pregnancy termination or to seek genetic counseling if a chromosomal abnormality is determined. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant, as well as exploring other options (termination of pregnancy or adoption). It is also important to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if fetal abnormalities are detected.

▶ **Social and Cultural Considerations:** Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the victim of sexual assault may experience (e.g., guilt, depression, anger) if there is possibility of pregnancy related to the assault.

▶ **Social and Cultural Considerations:** In patients with carcinoma, recognize anxiety related to test results and offer support. Provide teaching and information regarding the clinical implications of abnormal test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate.

▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor the patient's condition and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Instruct the patient in the use of home test kits for pregnancy approved by the U.S. Food and Drug Administration, as appropriate.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that surgical intervention may be necessary in the event of fetal demise.
- ▶ States understanding that the purpose of surgical intervention post-miscarriage is to ensure all of the tissue is removed to prevent infection and facilitate future viable pregnancies.

Skills

- ▶ Accurately describes symptoms that may indicate a miscarriage and should be reported to the HCP.
- ▶ Accurately describes the purpose of future laboratory (HCG) studies to monitor and verify the continuation of the pregnancy.

Attitude

- ▶ Agrees to attend a support group for those who have experienced fetal loss.
- ▶ Complies with scheduled follow-up laboratory studies to monitor pregnancy.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy chorionic villus, *Chlamydia* group antibody, chromosome analysis, CMV, estradiol, fetal fibronectin, α_1 -fetoprotein, CBC, hematocrit, CBC hemoglobin, CBC WBC count and differential, progesterone, rubella antibody, rubeola antibody, syphilis serology, toxoplasma antibody, US abdomen, and US biophysical profile obstetric.
- ▶ Refer to the Endocrine, Immune, and Reproductive systems tables at the end of the book for related tests by body system.

Human Immunodeficiency Virus Type 1 and Type 2 Antibodies

SYNONYM/ACRONYM: HIV-1/HIV-2.

COMMON USE: Test blood for the presence of antibodies that would indicate a human immunodeficiency virus (HIV) infection.

SPECIMEN: Serum (1 mL) collected in a red-top tube. Place separated serum into a standard transport tube within 2 h of collection.

NORMAL FINDINGS: (Method: Enzyme immunoassay) Negative.

DESCRIPTION: HIV is the etiological agent of AIDS and is transmitted through bodily secretions, especially by blood or sexual contact. The virus preferentially binds to the T4 helper lymphocytes and replicates within the cells using viral reverse transcriptase, integrase and protease enzymes. Current assays detect antibodies to one or more of several viral proteins. Public health guidelines recommend CD4 counts and viral load testing upon initiation of care for HIV; 3 to 4 mo before commencement of ART; every 3 to 4 mo, but no later than 6 mo, thereafter; and if treatment failure is suspected or otherwise when clinically indicated. Additionally, viral load testing should be requested 2 to 4 wk, but no later than 8 wk, after initiation of ART to verify success of therapy. In clinically stable patients, CD4 testing may be recommended every 6 to 12 mo rather than every 3 to 6 mo. Guidelines also state that treatment of asymptomatic patients should begin when CD4 count is less than 350 cells/microL; treatment is recommended when the patient is symptomatic regardless

of test results or when the patient is asymptomatic and CD4 count is between 350 and 500 cells/microL. Failure to respond to therapy is defined as a viral load greater than 200 copies/mL. Increased viral load may be indicative of viral mutations, drug resistance, or noncompliance to the therapeutic regimen. Testing for drug resistance is recommended if viral load is greater than 1,000 copies/mL. Initial screening is generally performed using a third-generation immunoassay for antibodies to HIV1/HIV2. The antibody screening tests most commonly used do not distinguish between HIV1 and HIV2. A reactive screen result is followed by repeat testing in duplicate. Positive or indeterminate results should be confirmed by Western blot assay where positive is defined by the Centers for Disease Control and Prevention (CDC) as presence of two of the three viral proteins: gp41, gp120 (from the viral membrane), and p24 (from the viral core). The newest HIV testing algorithm was developed jointly by the Association of Public Health Laboratories and the CDC. This

H new algorithm provides for earlier detection of acute infection as well as identification of established infection. Recommendations for initial screening call for the use of a fourth-generation immunoassay capable of the simultaneous detection of HIV antigen and antibody. The fourth-generation assays demonstrate the ability to detect infection 7 days earlier than third-generation assays. Positive initial screens should be followed by a rapid immunoassay that differentiates between HIV1 and HIV2 antibody. A negative or indeterminate supplemental antibody result should be followed by a nucleic acid amplification test (NAAT), during the period after infection has occurred but before the development of antibodies to the virus, to determine if HIV viral RNA is present. The HIV screening test is routinely recommended as part of a prenatal work-up and is required for evaluating donated blood units before release for transfusion. The CDC has structured its recommendations to increase identification of HIV-infected patients as early as possible; early identification increases treatment options, increases frequency of successful treatment, and can decrease further spread of disease. The CDC recommends the following:

- Include HIV testing in routine medical care; screening of all patients between the ages of 13 and 64 years of age as part of routine medical care, unless the patient requests to opt out.
- Implement new models to diagnose HIV infections outside medical settings; promote availability of rapid waived testing kits like OraQuick.

- Prevent new infections by working with persons diagnosed with HIV and their partners; adapt a voluntary opt-out approach that includes elimination of pretest counseling and written consent requirements.
- Further decrease prenatal transmission of HIV by incorporating HIV testing as a routine part of prenatal medical care and also perform third-trimester testing in areas with high rates of HIV infection among pregnant women.

HIV genotyping by polymerase chain reaction (PCR) methods may also be required to guide selection of medications for therapeutic regimens, assess potential for drug resistance, and monitor for transmission of drug resistant HIV. Genotyping is also useful to determine eligibility for new medications once resistance to conventional drugs has been identified.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate donated blood units before transfusion
- Perform as part of prenatal screening
- Screen organ transplant donors
- Test individuals who have documented and significant exposure to other infected individuals
- Test exposed high-risk individuals for detection of antibody (e.g., persons with multiple sex partners, persons with a history of other sexually transmitted diseases, IV drug users, infants born to infected mothers, allied health-care workers, public service employees who have contact with blood and blood products)

POTENTIAL DIAGNOSIS**Positive findings in**

- HIV1 or HIV2 infection

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may decrease HIV antibody levels include didanosine, dideoxycytidine, zalcitabine, and zidovudine.

- Nonreactive HIV test results occur during the acute stage of the disease, when the virus is present but antibodies have not sufficiently developed to be detected. It may take up to 6 mo for the test to become positive. During this stage, the test for HIV antigen may not confirm an HIV infection.
- Test kits for HIV are very sensitive. As a result, nonspecific reactions may occur, leading to a false-positive result.

NURSING IMPLICATIONS AND PROCEDURE**Potential Nursing Problems:**

Problem	Signs & Symptoms	Interventions
Knowledge <i>(Related to the emotional nature of the disease; new condition or diagnosis; lack of familiarity or understanding with disease and treatment; treatment complexity; fear; misinterpretation provided information)</i>	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management; verbalization of inaccurate information; lack of follow-through with directions	Identify patient's, family's, and significant others' concerns about HIV infection; explain the importance of receiving a hepatitis B vaccine, annual influenza vaccine and pneumococcal vaccine to protect health; assist patient to identify at-risk behaviors (sexual activities and IV drug use); instruct to avoid raw foods that can cause infection from bacteria and protozoa in compromised individuals; avoid emptying cat litter boxes to avoid organism exposure; discuss safe sex practices, ways to express intimacy without infection exposure; discuss the importance of using safe needles for recreational drug use; encourage drug rehabilitation and provide contact information; explain the importance of refraining from blood donation

(table continues on page 942)

Problem	Signs & Symptoms	Interventions
Infection (Related to decreased CD4 cells; detectable viral load; confirmed HIV antibody secondary to HIV infection)	Fever; swollen lymph glands in the armpit, neck, and groin; sore throat; rash; unexplained fatigue; achy muscles and joints with pain; headache; weight loss; fever and night sweats; diarrhea lasting more than a week; mouth, anal, and genital sores; pneumonia; blotches (red, brown, pink, or purplish) on or under the skin located in the mouth, or nose; depression; memory loss; neurologic disorders	Monitor and trend vial load and CD4 laboratory results; explain the purpose of antiviral medication; administer prescribed antiviral medication (nucleoside and nonnucleoside reverse transcriptase inhibitors, protease inhibitors, integrase strand transfer inhibitors, fusion inhibitors); ensure legal regulations regarding testing are adhered to; reinforce the necessity of strict adherence to the designated treatment plan
Nutrition (Related to fatigue; no appetite; oral candidiasis; nausea; vomiting; malabsorption; secondary to HIV infection)	Weight loss; pale dry skin; dry mucous membranes; documented inadequate caloric intake; loss of subcutaneous tissue, muscle, fat; hair pulls out easily; loss of muscle; decreased body mass index	Record accurate daily weight at the same time each day with the same scale; obtain an accurate nutritional history; assess for nausea and administer prescribed medication; inspect the mouth and assess for oral candidiasis infection; administer prescribed medications antimonial, anabolic steroids, testosterone supplements, human growth hormones, dronabinol; administer prescribed medications to enhance nutrient absorption within the gastrointestinal (GI) tract; discuss the patient use of total parenteral nutrition (TPN) to support nutrition with the health-care provider (HCP); assess attitude toward eating;

Problem**Signs & Symptoms****Interventions**

promote a dietary consult to evaluate current eating habits and best method of nutritional supplementation; develop short- and long-term eating strategies; monitor nutritional laboratory values such as albumin, transferrin, red blood cells (RBC), white blood cells (WBC), and serum electrolytes; encourage cultural home foods; provide a pleasant environment for eating; alter food seasoning to enhance flavor; ensure appropriate use of recommended vitamin supplements

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that this laboratory test can assist in evaluating for HIV infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune system, a history of high-risk behaviors, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform that patient that a report of the results will be made available to the

requesting HCP, who will discuss the results with the patient.

- Warn the patient that false-positive results occur and that the absence of antibody does not guarantee absence of infection, because the virus may be latent or may not have produced detectable antibody at the time of testing.

Social and Cultural Considerations:

Recognize anxiety related to test results, and be supportive of impaired activity related to weakness, perceived loss of independence, and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for AIDS information provided by the National Institutes of Health (www.aidsinfo.nih.gov) or the CDC (www.cdc.gov).

Social and Cultural Considerations:

Counsel the patient, as appropriate, regarding risk of transmission and proper prophylaxis, and reinforce the importance of strict adherence to the treatment regimen, including consultation with a pharmacist.

- Social and Cultural Considerations:** Inform patient that positive findings must be reported to local health department officials, who will question him or her regarding sexual partners.

- Social and Cultural Considerations:** Offer support, as appropriate, to patients who may be the victims of rape or sexual assault. Educate the patient regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases are explained. It is also important to discuss problems the patient may experience (e.g., guilt, depression, anger).

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- Inform the patient that retesting may be necessary.
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- Provide information regarding vaccine-preventable diseases where indicated (e.g., hepatitis B, human papillomavirus). Provide contact information, if desired, for the CDC (www.cdc.gov/vaccines/vpd-vac) and (www.cdc.gov/DiseasesConditions).
- Instruct the patient in the use of home test kits approved by the U.S. Food and Drug Administration, if prescribed. Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- States understanding of the importance of avoiding activities that can cause exposure to infecting organisms.
- States understanding that donating infected blood can put others at risk, and that donation is prohibited.

Skills

- Accurately describes interventions that can prevent exposure to opportunistic infections.
- Proficiently self-administers prescribed medication to treat or prevent opportunistic infection.

Attitude

- Complies with the recommendation to take precautions during sexual activity to avoid placing others at risk.
- Complies with suggested dietary changes and takes the recommended medication designed to improve caloric intake.

RELATED MONOGRAPHS:

- Related tests include biopsy bone marrow, bronchoscopy, CD4/CD8 enumeration, *Chlamydia* group antibody, CBC, CBC platelet count, CBC WBC count and differential, culture and smear mycobacteria, culture viral, cytology sputum, CMV, culture skin, gallium scan, HBV antibody and antigen, HCV antibody, human T-cell lymphotropic virus types I and II, laparoscopy abdominal, LAP, lymphangiogram, MRI

musculoskeletal, mediastinoscopy, β_2 -microglobulin, newborn screening, and syphilis serology.

Refer to the Immune System table at the end of the book for related tests by body system.

Human Leukocyte Antigen B27

SYNONYM/ACRONYM: HLA-B27.

COMMON USE: To assist in diagnosing juvenile rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, and Reiter's syndrome.

SPECIMEN: Whole blood (5 mL) collected in a green-top (heparin) or a yellow-top (acid-citrate-dextrose [ACD]) tube.

NORMAL FINDINGS: (Method: Flow cytometry) Negative (indicating absence of the antigen).

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Positive findings in

- Ankylosing spondylitis
- Inflammatory bowel disease

- Juvenile rheumatoid arthritis
- Psoriatic arthritis
- Reiter's syndrome
- Sacroiliitis
- Uveitis

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Human T-Lymphotropic Virus Type I and Type II Antibodies

SYNONYM/ACRONYM: HTLV-I/HTLV-II.

COMMON USE: To test the blood for the presence of antibodies that would indicate past or current human T-lymphocyte virus (HTLV) infection. Helpful in diagnosing certain types of leukemia.

SPECIMEN: Serum (1 mL) collected in a red-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Enzyme immunoassay) Negative.

This procedure is contraindicated for: N/A

Positive findings in
• HTLV-I/HTLV-II infection

POTENTIAL DIAGNOSIS

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

5-Hydroxyindoleacetic Acid

SYNONYM/ACRONYM: 5-HIAA.

COMMON USE: To assist in diagnosing carcinoid tumors.

SPECIMEN: Urine (10 mL) from a timed specimen collected in a clean plastic collection container with boric acid as a preservative.

NORMAL FINDINGS: (Method: High-pressure liquid chromatography)

Conventional Units	SI Units (Conventional Units × 5.23)
2–7 mg/24 hr	10.5–36.6 micromol/24 hr

This procedure is contraindicated for: N/A

- Ovarian carcinoid tumors
- Whipple's disease

POTENTIAL DIAGNOSIS

Increased in
Serotonin is produced by the enterochromaffin cells of the small intestine and secreted ectopically by tumor cells. It is converted to 5-HIAA in the liver and excreted in the urine. Increased values are associated with malabsorption conditions, but the relationship is unclear.

- Celiac and tropical sprue
- Cystic fibrosis
- Foregut and midgut carcinoid tumors
- Oat cell carcinoma of the bronchus

Decreased in
The documented relationship between decreased levels of serotonin, defective amino acid metabolism, and mental illness is not well understood.

- Depressive illnesses
- Hartnup's disease
- Mastocytosis
- Phenylketonuria
- Renal disease (*related to decreased renal excretion*)
- Small intestine resection (*related to a decrease in enterochromaffin-producing cells*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Hypersensitivity Pneumonitis Serology

SYNONYM/ACRONYM: Farmer's lung disease serology, extrinsic allergic alveolitis.

COMMON USE: To assist in identification of pneumonia related to inhaled allergens containing *Aspergillus* or actinomycetes (dust, mold, or chronic exposure to moist organic materials).

SPECIMEN: Serum (2 mL) collected in a red-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Immunodiffusion) Negative.

This procedure is contraindicated for: N/A

Increased in

- Hypersensitivity pneumonitis

POTENTIAL DIAGNOSIS

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

H

Hysterosalpingography

SYNONYM/ACRONYM: Hysterogram, uterography, uterosalpingography.

COMMON USE: To visualize and assess the uterus and fallopian tubes to assess for obstruction, adhesions, malformations, or injuries that may be related to infertility.

AREA OF APPLICATION: Uterus and fallopian tubes.

CONTRAST: Iodinated contrast medium.

DESCRIPTION: Hysterosalpingography (HSG) is performed as part of an infertility study to identify anatomical abnormalities of the uterus or occlusion of the fallopian tubes. The procedure allows visualization of the uterine cavity, fallopian tubes, and peritubal area after the injection of contrast medium into the cervix. The

contrast medium should flow through the uterine cavity, through the fallopian tubes, and into the peritoneal cavity, where it is absorbed if no obstruction exists. The procedure has therapeutic indications in that passage of the contrast medium through the tubes may clear mucous plugs, straighten kinked tubes, or break

up adhesions, thus restoring fertility. This procedure is also used to evaluate the fallopian tubes after tubal ligation and to evaluate the results of reconstructive surgery.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
-  Conditions associated with pre-existing renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic.**

-  Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
-  Patients with bleeding disorders, **because the puncture site may not stop bleeding.**
-  Patients with menses, undiagnosed vaginal bleeding, or pelvic inflammatory disease.

INDICATIONS

- Assist in the investigation of abnormal uterine bleeding, amenorrhea, or recurrent abortion.
- Confirm the presence of fistulas, adhesions, polyps, or pelvic masses.
- Confirm tubal abnormalities such as adhesions and occlusions; evaluate the patency of the tubes.
- Confirm uterine abnormalities such as congenital malformation, traumatic injuries, missing or ectopic contraceptive devices, or indicate the presence of foreign bodies.
- Detect bicornate uterus.
- Evaluate adequacy of surgical tubal ligation and reconstructive surgery.

POTENTIAL DIAGNOSIS

Normal findings in

- Contrast medium flowing freely into the fallopian tubes and from the uterus into the peritoneal cavity
- Normal position, shape, and size of the uterine cavity

Abnormal findings in

- Bicornate uterus
- Developmental abnormalities
- Extrauterine pregnancy
- Internal scarring
- Kinking of the fallopian tubes due to adhesions
- Partial or complete blockage of fallopian tube(s)
- Tumors
- Uterine cavity anomalies
- Uterine fistulas

- Uterine masses or foreign body
- Uterine fibroid tumors (leiomyomas)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Insufficient injection of contrast medium.
- Excessive traction during the test or tubal spasm, which may cause the appearance of a stricture in an otherwise normal fallopian tube.

Other considerations

- Excessive traction during the test may displace adhesions, making the fallopian tubes appear normal.
- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow pretesting preparations may cause the procedure to be canceled or repeated.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the uterus and fallopian tubes.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent barium or other radiological contrast procedures. Ensure that barium studies were performed more than 4 days before the hysterosalpingography.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**

Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Explain to the patient that she may feel temporary sensations of nausea, dizziness, slow heartbeat, and menstrual-like cramping during the procedure, as well as shoulder pain from subphrenic irritation from the contrast medium as it spills into the peritoneal cavity. Inform the patient that the procedure is performed in a radiology department by a health-care provider (HCP), with support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during and after the procedure.
- ▶ Instruct the patient to take a laxative or a cathartic, as ordered, on the evening before the examination.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction or department protocol.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

- Risks from HSG can include uterine perforation, exposure to radiation, infection, allergic reaction to contrast medium, heavy vaginal bleeding, uterine perforation, severe abdominal pain or cramping, pelvic infection (uterine or of the fallopian tubes), and pulmonary embolism.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure the patient has complied with pretesting preparations prior to the procedure.

- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Assess for completion of bowel preparation according to the institution's procedure. Administer enemas or suppositories on the morning of the test, as ordered.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in a lithotomy position on the fluoroscopy table.
- ▶ A kidney, ureter, and bladder film is taken to ensure that no stool, gas, or barium will obscure visualization of the uterus and fallopian tubes.
- ▶ A speculum is inserted into the vagina, and contrast medium is introduced into the uterus through the cervix via a cannula, after which both fluoroscopic and radiographic images are taken.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications and activity, as directed by the HCP.
- ▶ Observe for delayed reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Inform the patient that a vaginal discharge is common and that it may

be bloody, lasting 1 to 2 days after the test.

- ▶ Inform the patient that dizziness and cramping may follow this procedure, and that analgesia may be given if there is persistent cramping. Instruct the patient to contact the HCP in the event of severe cramping or profuse bleeding.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CT abdomen, laparoscopy gynecological, MRI abdomen, US obstetric, US pelvis, and uterine fibroid embolization.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Hysteroscopy

SYNONYM/ACRONYM: N/A.

COMMON USE: To visualize and assess the endometrial lining of the uterus to assist in diagnosing disorders such as fibroids, cancer, and polyps.

AREA OF APPLICATION: Uterus.

CONTRAST: Carbon dioxide, saline.

DESCRIPTION: Hysteroscopy is a diagnostic or surgical procedure of the uterus done using a thin telescope (hysteroscope), which is inserted through the cervix with minimal or no dilation. Normal saline, glycine, or carbon dioxide is used to fill and distend the uterus. The inner surface of the uterus is examined, and laser beam or electrocautery can be accomplished during the procedure. Diagnostic hysteroscopy is used to diagnose uterine abnormalities and may be completed in conjunction with a dilatation and

curettage (D & C). This minor surgical procedure is generally done to assess abnormal uterine bleeding or repeated miscarriages. An operative hysteroscopy is done instead of abdominal surgery to treat many uterine conditions such as septums or fibroids (myomas). A resectoscope (a hysteroscope that uses high-frequency electrical current to cut or coagulate tissue) may be used to remove any localized myomas. Local, regional, or general anesthesia can be used, but usually general anesthesia is needed. The procedure

may done in a health-care practitioner's office, but if done as an outpatient surgical procedure, it is usually completed in a hospital setting.

This procedure is contraindicated for

- ◆ Patients with bleeding disorders or receiving anticoagulant therapy *related to the potential for continued bleeding as a result of the procedure.*

INDICATIONS

- Confirm the presence of uterine fibroids
- Aid in the diagnosis and/or treatment of intrauterine adhesions
- Investigate abnormal uterine bleeding
- Assist in the removal of intrauterine devices
- Assist in the removal of uterine polyps

POTENTIAL DIAGNOSIS

Normal findings in

- Normal uterine appearance

Abnormal findings in

- Areas of active bleeding
- Adhesions
- Displaced intrauterine devices
- Fibroid tumors
- Polyps
- Uterine septum

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status may interfere with the test results.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ◆ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ◆ **Patient Teaching:** Inform the patient that this procedure can assist in assessing uterine health.
- ◆ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ◆ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ◆ Record the date of last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ◆ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ◆ Review the procedure with the patient. Address concerns about pain and explain that a local anesthetic spray or liquid may be applied to the cervix to ease with insertion of the hysteroscope if general anesthesia is not used. Inform the patient that the procedure is usually performed in the office of a health-care provider (HCP) or a surgery suite and takes about 30–45 min.
- ◆ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ◆ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ◆ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be

located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ Instruct the patient not to douche or use tampons or vaginal medications for 24 hr prior to the procedure.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Complications of the procedure may include bleeding.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary and fluid restrictions for 8 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Place the patient in the supine position on an exam table. Cleanse

the vaginal area, and cover with a sterile drape.

- ▶ Monitor the patient for complications related to the procedure.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity as directed by the HCP.
- ▶ Instruct the patient to immediately report symptoms such as excessive uterine bleeding or fever.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CBC hematocrit, CBC hemoglobin, CT abdomen, HCG, KUB, and US pelvis.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Immunofixation Electrophoresis, Blood and Urine

SYNONYM/ACRONYM: IFE.

COMMON USE: To identify the individual types of immunoglobulins, toward diagnosing diseases such as multiple myeloma, and to evaluate effectiveness of chemotherapy.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum in a standard transport tube within 2 hr of collection. Urine (10 mL) from a random or timed collection in a clean plastic container.

NORMAL FINDINGS: (Method: Immunoprecipitation combined with electrophoresis) Test results are interpreted by a pathologist. Normal placement and intensity of staining provide information about the immunoglobulin bands.

DESCRIPTION: Immunofixation electrophoresis (IFE) is a qualitative technique that provides a detailed separation of individual immunoglobulins according to their electrical charges followed by the application of specific antiserum (anti-IgM, anti kappa, etc.) and a stain, to help visualize the patterns. It is usually requested when there is an abnormality in the gamma globulin fraction of a serum protein electrophoresis; either monoclonal or polyclonal. IFE is frequently used to identify the three main immunoglobulin groups (IgG, IgM, and IgA) and the light chain proteins (kappa and lambda). Antisera for IgE and IgD are available for use, if indicated. Abnormalities are revealed by changes produced in the individual bands, such as displacement compared to a normal pattern, intense color which reflects an increase, or absence of color which reflects a decrease. Urine IFE has replaced the Bence Jones screening test for light chains. IFE has replaced immunoelectrophoresis because it is more sensitive and easier to interpret. IFE is used to help detect, diagnose, and monitor the course and treatment of conditions like

kidney disease, multiple myeloma and Waldenström's macroglobulinemia.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of multiple myeloma and amyloidosis
- Assist in the diagnosis of suspected immunodeficiency
- Assist in the diagnosis of suspected immunoproliferative disorders, such as multiple myeloma and Waldenström's macroglobulinemia
- Identify biclonal or monoclonal gammopathies
- Identify cryoglobulinemia
- Monitor the effectiveness of chemotherapy or radiation therapy

POTENTIAL DIAGNOSIS

See the "Immunoglobulins A, D, G, and M" and "Protein, total and fractions" studies.

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase immunoglobulin levels include asparaginase, cimetidine, and narcotics.

- Drugs that may decrease immunoglobulin levels include dextran, oral contraceptives, methylprednisolone (high doses), and phenytoin.
- Chemotherapy and radiation treatments may alter the width of the bands and make interpretation difficult.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Powerlessness <i>(Related chronic illness; treatment for illness; loss of ability to provide self-care; progressive debilitation; terminal prognosis)</i>	Expression of loss of control over situation, self, outcome of disease; passive; apathetic; submissive; decreased participation in self-care; reluctant to express feelings	Assess need to be in control; assess feelings of hopelessness, depression, apathy; assist to identify situations that contribute to a feeling of powerlessness; assess the impact of the sense of powerlessness on the patient's sense of self; encourage verbalization of feelings; discuss therapeutic options offered by health-care provider (HCP); assist to identify strengths; identify coping strategies; encourage being responsible for self-care and personal environment to increase sense of control; give positive feedback
Hopelessness <i>(Related to chronic illness; impaired functionality; prolonged pain and discomfort)</i>	Decreased affect; decreased response to stimuli; feeling of emptiness; alterations in sleep patterns and appetite; expressions of apathy; withdrawn; states life has no meaning	Assess role of illness in relation to expressions of helplessness; assess grooming (energy to provide good personal hygiene); assess level of appetite; assess verbalization of helplessness; provide opportunities to express feelings in a safe environment; support development of a trusting relationship to decrease feelings of isolation; encourage verbalization of personal strengths and weaknesses; encourage realistic hope; assist in identification of coping skills

(table continues on page 956)

Problem	Signs & Symptoms	Interventions
Mobility (<i>Related to pain; weakness; depression; fatigue; decreased muscle strength; decreased coordination</i>)	Decreased purposeful movement; difficulty completing activities of daily living; limited range of motion; reluctance to move; pain	Assess the patient's ability to perform independent range-of-motion exercises; encourage performance of range-of-motion exercises; encourage and assist in moving every 2 hr to relieve tissue pressure; assist with activities of daily living; encourage use of assistive devices as needed to support mobility
Protection (<i>Related to failure of bone marrow; replacement of bone marrow by neoplastic cells; insufficient autoimmune response; chemotherapy; bone marrow transplant</i>)	Bleeding; infection; anemia	Monitor and trend HGB/HCT; monitor and trend platelets and red blood cells (RBCs); monitor for symptoms of infection; take temperature every 4 hr; institute bleeding precautions, soft toothbrushes, avoid aspirin, avoid IM or IV injections, coordinate laboratory draws to minimize venipuncture; administer prescribed steroids, erythropoietin; administer prescribed blood and blood products; avoid at-risk activities that could cause trauma; discuss exposure to microbes that could result in infection

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing the immune system.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results. Assess

- whether the patient received any vaccinations or immunizations within the last 6 mo or any blood or blood components within the last 6 wk.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
- ▶ Note that usually a 24-hr time frame for urine collection is ordered. Inform

the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.

- ▶ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture as appropriate.

Blood

- ▶ Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Urine

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the

meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.

- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Blood or Urine

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Provide contact information for support groups.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding of the importance of ambulation to prevent demineralization and support bone health
- ▶ States understanding of the importance of using assistive devices to support mobility and decrease injury risk.

Skills

- ▶ Strictly avoids at-risk activities that could result in trauma and bleeding
- ▶ *Makes dietary selections that include omitting fresh fruit to decrease exposure to bacteria*

Attitude

- Adheres to recommended therapeutic regime
- Makes a positive effort to address feelings of hopelessness and powerlessness

RELATED MONOGRAPHS:

- Related tests include anion gap, biopsy bone, biopsy bone marrow, biopsy liver, biopsy lymph node, cold

agglutinin, CBC, CBC WBC count and differential, cryoglobulin, ESR, fibrinogen, quantitative immunoglobulin levels, LAP, liver and spleen scan, β -2-microglobulin, platelet antibodies, protein total and fractions, and UA.

- Refer to the Hematopoietic and Immune systems tables at the end of the book for related tests by body system.

Immunoglobulin E

SYNONYM/ACRONYM: IgE.

COMMON USE: To assess immunoglobulin E (IgE) levels in order to identify the presence of an allergic or inflammatory immune response.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional & SI Units
Newborn	Less than 12 International Units/L
Less than 1 yr	Less than 50 International Units/L
2–4 yr	Less than 200 International Units/L
5–9 yr	Less than 300 International Units/L
10 yr and older	Less than 100 International Units/L

DESCRIPTION: Immunoglobulin E (IgE) is an antibody whose primary response is to allergic reactions and parasitic infections. Most of the body's IgE is bound to specialized tissue cells; little is available in the circulating blood. IgE binds to the membrane of special granulocytes called *basophils* in the circulating blood and *mast cells* in the tissues. Basophil and mast cell membranes have receptors for IgE. Mast cells are abundant in the skin and the tissues lining the respiratory and

alimentary tracts. When IgE antibody becomes cross-linked with antigen/allergen, the release of histamine, heparin, and other chemicals from the granules in the cells is triggered. A sequence of events follows activation of IgE that affects smooth muscle contraction, vascular permeability, and inflammatory reactions. The inflammatory response allows proteins from the bloodstream to enter the tissues. Helminths (worm parasites) are especially susceptible to

immunoglobulin-mediated cytotoxic chemicals. The inflammatory reaction proteins attract macrophages from the circulatory system and granulocytes, such as eosinophils, from circulation and bone marrow. Eosinophils also contain enzymes effective against the parasitic invaders.

A nasal smear can be examined for the presence of eosinophils to screen for allergic conditions. Either a single smear or smears of nasal secretions from each side of the nose should be submitted, at room temperature, for Hansel staining and evaluation. Normal findings vary by laboratory but generally, greater than 10–15% is considered eosinophilia or increased presence of eosinophils. Results may be invalid for patients already taking local or systemic corticosteroids.

This procedure is contraindicated for: N/A

INDICATIONS

Assist in the evaluation of allergy and parasitic infection

POTENTIAL DIAGNOSIS

Increased in

Conditions involving allergic reactions or infections that stimulate production of IgE.

- Alcoholism (*alcohol may play a role in the development of*

environmentally instigated IgE-mediated hypersensitivity)

- Allergy
- Asthma
- Bronchopulmonary aspergillosis
- Dermatitis
- Eczema
- Hay fever
- IgE myeloma
- Parasitic infestation
- Rhinitis
- Sinusitis
- Wiskott-Aldrich syndrome

Decreased in

- Advanced carcinoma (*related to generalized decrease in immune system response*)
- Agammaglobulinemia (*related to decreased production*)
- Ataxia-telangiectasia (*evidenced by familial immunodeficiency disorder*)
- IgE deficiency

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may cause a decrease in IgE levels include phenytoin and tryptophan.
- Penicillin G has been associated with increased IgE levels in some patients with drug-induced acute interstitial nephritis.
- Normal IgE levels do not eliminate allergic disorders as a possible diagnosis.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Powerlessness (<i>Related to chronic illness;</i>	Expression of loss of control over situation, self,	Assess need to be in control; assess feelings of hopelessness, depression,

(table continues on page 960)

Problem	Signs & Symptoms	Interventions
<i>treatment for illness; loss of ability to provide self-care; progressive debilitation; terminal prognosis)</i>	outcome of disease; passive; apathetic; submissive; decreased participation in self-care; reluctant to express feelings	apathy; assist to identify situations that contribute to a feeling of powerlessness; assess the impact of the sense of powerlessness on the patient's sense of self; encourage verbalization of feelings; discuss therapeutic options offered by health-care provider (HCP); assist to identify strengths; identify coping strategies; encourage being responsible for self-care and personal environment to increase sense of control; provide positive feedback
Mobility (<i>Related to pain; weakness; depression; fatigue; decreased muscle strength; decreased coordination)</i>	Decreased purposeful movement; difficulty completing activities of daily living; limited range of motion; reluctance to move; pain	Assess the patient's ability to perform independent range-of-motion exercises; encourage performance of range-of-motion exercises; encourage and assist in moving every 2 hr to relieve tissue pressure; assist with activities of daily living; encourage use of assistive devices as needed to support mobility
Knowledge (<i>Related to recent diagnosis; complexity of treatment; poor understanding of provided information; cultural or language barriers; anxiety; emotional disturbance; unfamiliarity with medical management)</i>	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management; verbalizes inaccurate information; lack of follow-through with directions	Identify patient's, family's, and significant others' concerns about disease process; provide information about disease process, bone marrow analysis, and associated diagnostic studies that may be necessary (computed tomography [CT], bone scan); facilitate and monitor ordered laboratory studies (CBC, immunoglobulin levels, C-reactive protein [CRP], protein electrophoresis); discuss possible treatment modalities, chemotherapy, proteasome inhibitors, palliative radiation therapy, drug administration, stem cell transplant, pain management

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identification of an allergic or inflammatory response.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop

bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased IgE levels may be associated with allergy. Consideration should be given to diet if the patient has food allergies.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the patient's condition and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Explain that a negative result does not necessarily preclude the presence of a sensitivity to an allergen.

Expected Patient Outcomes:**Knowledge**

- ▶ Understands the importance of maintaining an uncluttered home environment to decrease injury risk
- ▶ Understands the importance of conserving energy by including frequent rest periods during times of activity

Skills

- ▶ Successfully changes position every 2 hr to decrease risk of skin breakdown
- ▶ Demonstrates the ability to perform range-of-motion exercises proficiently

Attitude

- ▶ Agrees to accept assistance with activities of daily living to enhance comfort and safety

▸ Agrees to perform range-of-motion activities 3 times a day to decrease contracture risk

RELATED MONOGRAPHS:

▸ Related tests include allergen-specific IgE, alveolar/arterial gradient, biopsy intestine, biopsy liver, biopsy muscle,

blood gases, carbon dioxide, CBC, CBC platelet count, CBC WBC count and differential, eosinophil count, fecal analysis, hypersensitivity pneumonitis, lung perfusion scan, and PFT.

▸ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Immunoglobulins A, D, G, and M

SYNONYM/ACRONYM: IgA, IgD, IgG, and IgM.

COMMON USE: To quantitate immunoglobulins A, D, G, and M as indicators of immune system function, to assist in the diagnosis of immune system disorders such as multiple myeloma, and to investigate transfusion anaphylaxis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum in a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Nephelometry)

Age	Conventional Units	SI Units
<i>Immunoglobulin A</i>		<i>(Conventional Units × 0.01)</i>
Newborn	1–4 mg/dL	0.01–0.04 g/L
1–9 mo	2–80 mg/dL	0.02–0.8 g/L
10–12 mo	15–90 mg/dL	0.15–0.9 g/L
2–3 yr	18–150 mg/dL	0.18–1.5 g/L
4–5 yr	25–160 mg/dL	0.25–1.6 g/L
6–8 yr	35–200 mg/dL	0.35–2 g/L
9–12 yr	45–250 mg/dL	0.45–2.5 g/L
Older than 12 yr	40–350 mg/dL	0.40–3.5 g/L
<i>Immunoglobulin D</i>		<i>(Conventional Units × 10)</i>
Newborn	Greater than 2 mg/dL	Greater than 20 mg/L
Adult	Less than 15 mg/dL	Less than 150 mg/L
<i>Immunoglobulin G</i>		<i>(Conventional Units × 0.01)</i>
Newborn	650–1,600 mg/dL	6.5–16 g/L
1–9 mo	250–900 mg/dL	2.5–9 g/L
10–12 mo	290–1,070 mg/dL	2.9–10.7 g/L
2–3 yr	420–1,200 mg/dL	4.2–12 g/L
4–6 yr	460–1,240 mg/dL	4.6–12.4 g/L
Greater than 6 yr	650–1,600 mg/dL	6.5–16 g/L
<i>Immunoglobulin M</i>		<i>(Conventional Units × 0.01)</i>
Newborn	Less than 25 mg/dL	Less than 0.25 g/L
1–9 mo	20–125 mg/dL	0.2–1.25 g/L
10–12 mo	40–150 mg/dL	0.4–1.5 g/L
2–8 yr	45–200 mg/dL	0.45–2 g/L

Age	Conventional Units	SI Units
9–12 yr	50–250 mg/dL	0.5–2.5 g/L
Greater than 12 yr	50–300 mg/dL	0.5–3 g/L

DESCRIPTION: Immunoglobulins A, D, E, G, and M are made by plasma cells in response to foreign substances. Immunoglobulins neutralize toxic substances, support phagocytosis, and destroy invading microorganisms. They are made up of heavy and light chains.

Immunoglobulins produced by the abnormal proliferation of a single plasma cell (clone) are called *monoclonal*. Polyclonal increases result when multiple cell lines produce excessive amounts of antibody. IgA is found mainly in secretions such as tears, saliva, and breast milk. It is believed to protect mucous membranes from viruses and bacteria. The function of IgD is not well understood. For details on IgE, see the monograph titled “Immunoglobulin E.” IgG is the predominant serum immunoglobulin and is important in long-term defense against disease. It is the only antibody that crosses the placenta. IgM is the largest immunoglobulin, and it is the first antibody to react to an antigenic stimulus. IgM also forms natural antibodies, such as ABO blood group antibodies. The presence of IgM in cord blood is an indication of congenital infection.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of multiple myeloma
- Evaluate humoral immunity status
- Monitor therapy for multiple myeloma

- IgA: Evaluate patients suspected of IgA deficiency prior to transfusion. Evaluate anaphylaxis associated with the transfusion of blood and blood products (anti-IgA antibodies may develop in patients with low levels of IgA, possibly resulting in anaphylaxis when donated blood is transfused)

POTENTIAL DIAGNOSIS

Increased in

IgA

Polyclonal

- Chronic liver disease (*pathophysiology is unclear*)
- Immunodeficiency states, such as Wiskott-Aldrich syndrome (*inherited condition of lymphocytes characterized by increased IgA and IgE*)
- Inflammatory bowel disease (*IgG and/or IgA antibody positive for Saccharomyces cerevisiae with negative perinuclear-antineutrophil cytoplasmic antibody is indicative of Crohn's disease*)
- Lower gastrointestinal (GI) cancer (*pathophysiology is unclear*)
- Rheumatoid arthritis (*pathophysiology is unclear*)

Monoclonal

- IgA-type multiple myeloma (*related to excessive production by a single clone of plasma cells*)

IgD

Polyclonal (*pathophysiology is unclear, but increases are associated with increases in IgM*)

- Certain liver diseases
- Chronic infections
- Connective tissue disorders

Monoclonal

- IgD-type multiple myeloma (*related to excessive production by a single clone of plasma cells*)

IgG

(Conditions that involve inflammation and/or development of an infection stimulate production of IgG.)

Polyclonal

- Autoimmune diseases, such as systemic lupus erythematosus, rheumatoid arthritis, and Sjögren's syndrome
- Chronic liver disease
- Chronic or recurrent infections
- Intrauterine devices (*the IUD creates a localized inflammatory reaction that stimulates production of IgG*)
- Sarcoidosis

Monoclonal

- IgG-type multiple myeloma (*related to excessive production by a single clone of plasma cells*)
- Leukemias
- Lymphomas

IgM

Polyclonal (*humoral response to infections and inflammation; both acute and chronic*)

- Active sarcoidosis
- Chronic hepatocellular disease
- Collagen vascular disease
- Early response to bacterial or parasitic infection
- Hyper-IgM dysgammaglobulinemia
- Rheumatoid arthritis
- Variable in nephrotic syndrome
- Viral infection (hepatitis or mononucleosis)

Monoclonal

- Cold agglutinin hemolysis disease
- Malignant lymphoma

- Neoplasms (especially in GI tract)
- Reticulosis
- Waldenström's macroglobulinemia (*related to excessive production by a single clone of plasma cells*)

Decreased in

IgA

- Ataxia-telangiectasia
- Chronic sinopulmonary disease
- Genetic IgA deficiency

IgD

- Genetic IgD deficiency
- Malignant melanoma of the skin
- Pre-eclampsia

IgG

- Burns
- Genetic IgG deficiency
- Nephrotic syndrome
- Pregnancy

IgM

- Burns
- Secondary IgM deficiency associated with IgG or IgA gammopathies

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase immunoglobulin levels include asparaginase, cimetidine, and narcotics.
- Drugs that may decrease immunoglobulin levels include dextran, oral contraceptives, methylprednisolone (high doses), and phenytoin.
- Chemotherapy, immunosuppressive therapy, and radiation treatments decrease immunoglobulin levels.
- Specimens with macroglobulins, cryoglobulins, or cold agglutinins tested at cold temperatures may give falsely low values.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Hopelessness <i>(Related to chronic illness; impaired functionality; prolonged pain and discomfort)</i>	Decreased affect; decreased response to stimuli; feeling of emptiness; alterations in sleep patterns and appetite; expressions of apathy; withdrawn; states life has no meaning	Assess role of illness in relation to expressions of helplessness; assess grooming (energy to provide good personal hygiene); assess level of appetite; assess verbalization of helplessness; provide opportunities to express feelings in a safe environment; support development of a trusting relationship to decrease feelings of isolation; encourage verbalization of personal strengths and weaknesses; encourage realistic hope; assist in identification of coping skills
Protection <i>(Related to failure of bone marrow; replacement of bone marrow by neoplastic cells; insufficient autoimmune response; chemotherapy; bone marrow transplant)</i>	Bleeding; infection; anemia	Monitor and trend HGB/HCT; monitor and trend platelets and red blood cells (RBCs); monitor for symptoms of infection; take temperature every 4 hr; institute bleeding precautions, soft toothbrushes, avoid aspirin, avoid IM or IV injections, coordinate laboratory draws to minimize venipuncture; administer prescribed steroids, erythropoietin; administer prescribed blood and blood products; avoid at-risk activities that could cause trauma; discuss exposure to microbes that could result in infection
Pain <i>(Related to invasion of bone marrow and</i>	Self-report of pain; guarding; crying; moaning;	Assess pain characteristics, skeletal pain, low back, ribs; assess level of pain with

(table continues on page 966)

Problem	Signs & Symptoms	Interventions
pathological fractures secondary to medication diagnosis [multiple myeloma]	sleeplessness; restlessness; emotional symptoms of distress; agitation; facial grimace; rocking motions; irritability; diaphoresis; altered blood pressure and heart rate; nausea; vomiting	movement; identify pain modalities that have relieved pain in the past; administer prescribed pain medication; monitor and trend vital signs; recommend use of nonpharmacologic pain management modalities, imagery, distraction, music, relaxation, correct body alignment

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assess the immune system by evaluating the levels of immunoglobulins in the blood.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain to the patient that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological

support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient. A patient with IgA deficiency should not receive gamma globulin. Administration of gamma globulin may initiate sensitization of the immune system that could result in an anaphylactic shock during a subsequent RBC product transfusion, related to instigation by donor IgA in the product. IgA deficiency is a lifelong condition, if transfusion is necessary and products from an IgA-deficient donor are unavailable, washed RBCs can be used to decrease the risk of transfusion reaction.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Provide information on the disease process as it relates to altered laboratory results.

Expected Patient Outcomes:**Knowledge**

- ▶ States understanding of the importance of notifying the HCP

if the pain management regime is ineffective

- ▶ States understanding that a combination of pain management modalities may be most effective in managing pain

Skills

- ▶ Describes appropriate use of pain scale for quantifying the severity of pain experienced
- ▶ Demonstrates proficiency in using a selected nonpharmacological pain management strategy to decrease pain intensity

Attitude

- ▶ Complies with the recommendation to try using nonpharmacological measures to decrease pain
- ▶ Complies with the recommendation to take pain medication around the clock to decrease the risk of peak pain periods

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, anion gap, ANA, bilirubin, biopsy bone, biopsy bone marrow, biopsy liver, biopsy lymph node, blood groups and antibodies, cold agglutinin, CBC, CBC WBC count and differential, Coomb's antiglobulin (direct and indirect), cryoglobulin, ESR, fibrinogen, IFE, quantitative immunoglobulin levels, GGT, LAP, liver and spleen scan, beta-2-microglobulin, platelet antibodies, protein total and fractions, RF, and uric acid.
- ▶ Refer to the Hematopoietic and Immune systems tables at the end of the book for related tests by body system.

Immunosuppressants: Cyclosporine, Methotrexate, Everolimus, Sirolimus, and Tacrolimus

SYNONYM/ACRONYM: *Cyclosporine* (Sandimmune), *methotrexate* (MTX, amethopterin, Folex, Rheumatrex), *methotrexate sodium* (Mexate), *everolimus* (Afinitor, Certican, Zortress), *sirolimus* (Rapamycin), *tacrolimus* (Prograf).

COMMON USE: To monitor appropriate drug dosage of immunosuppressant related to organ transplant maintenance.

SPECIMEN: Whole blood (1 mL) collected in lavender-top tube for cyclosporine, everolimus; sirolimus; tacrolimus. Serum (1 mL) collected in a red-top tube for methotrexate; specimen must be protected from light.

Immunosuppressant	Route of Administration	Recommended Collection Time
Cyclosporine	Oral or intravenous	12 hr after dose or immediately prior to next dose
Methotrexate	Oral	Varies according to dosing protocol
	Intramuscular	Varies according to dosing protocol
Everolimus	Oral	Immediately prior to next dose
Sirolimus	Oral	Immediately prior to next dose
Tacrolimus	Oral	Immediately prior to next dose

Leucovorin therapy, also called leucovorin rescue, is used in conjunction with administration of methotrexate. Leucovorin, a fast-acting form of folic acid, protects healthy cells from the toxic effects of methotrexate.

NORMAL FINDINGS: (Method: Immunoassay for cyclosporine and methotrexate; liquid chromatography with tandem mass spectrometry for everolimus, sirolimus, and tacrolimus)

Therapeutic Dose	SI Units (Conventional Units x 0.832)	Half-Life (hr)	Volume of Distribution (L/kg)	Protein Binding (%)	Excretion
Cyclosporine	<i>Conventional Units</i> 100–300 ng/mL renal transplant 200–350 ng/mL cardiac, hepatic, pancreatic transplant	8–24 8–24	4–6 4–6	90 90	Renal Renal
Methotrexate	100–300 ng/mL bone marrow transplant Dependent on therapeutic approach Low dose: 0.5–1 micromol/L High dose: Less than 5 micromol/L at 24 h; less than 0.5 micromol/L at 48 h; less than 0.1 micromol/L at 72 h	8–24 5–9	4–6 0.4–1	90 50–70	Renal Renal
Everolimus	<i>Conventional Units</i> Transplant: 3–8 ng/mL	18–35 (kidney); 30–35 (liver) 18–35	128–589	75	Biliary
Sirolimus	Oncology: 5–10 ng/mL Maintenance phase: renal transplant: 4–12 ng/mL; liver transplant: 12–20 ng/mL	46–78	128–589 4–20	75 92	Biliary Biliary
Tacrolimus	Maintenance phase: renal transplant: 6–12 ng/mL; liver transplant: 4–10 ng/mL; pancreas transplant: 10–18 ng/mL; bone marrow transplant: 10–20 ng/mL	10–14	1.5	99	Biliary

Therapeutic targets for the initial phase post-transplantation are slightly higher than during the maintenance phase and are influenced by the specific therapy chosen for each patient with respect to coordination of treatment for other conditions and corresponding therapies. Therapeutic ranges for everolimus, sirolimus, and tacrolimus assume concomitant administration of cyclosporine and steroids.

DESCRIPTION: Cyclosporine is an immunosuppressive drug used in the management of organ rejection, especially rejection of heart, liver, pancreas, and kidney transplants. Its most serious side effect is renal impairment or renal failure. Cyclosporine is often administered in conjunction with corticosteroids (e.g., prednisone) for its anti-inflammatory or immune-suppressing properties and with other drugs (e.g., everolimus, sirolimus, tacrolimus) to reduce graft-versus-host disease. Methotrexate is a highly toxic drug that causes cell death by disrupting DNA synthesis. Methotrexate is also used in the treatment of rheumatoid arthritis, psoriasis, polymyositis, and Reiter's syndrome. These drugs are metabolized by the cytochrome enzyme, CYP3A4 or CYP3A5, which is essential to achieve the desired therapeutic effect. Testing for specific CYP450 genotype defects can be performed in some laboratories on blood and buccal specimens. Counseling and informed written consent are generally required for genetic testing. Test results can identify poor and ultrasensitive drug metabolizers. This allows for the possibility of personalized adjustments to their medication regimen or decisions to seek alternative drugs which in turn results in safer, more effective treatment.

Many factors must be considered in effective dosing and monitoring of therapeutic drugs, including patient age; weight; interacting medications; electrolyte balance; protein levels; water balance; conditions that affect absorption and excretion; as well as foods, herbals, vitamins, and minerals that can either potentiate or inhibit the intended target concentration.

Important note: These medications are metabolized and excreted by the

kidneys and are therefore contraindicated in patients with renal disease and cautiously advised in patients with renal impairment. Information regarding medications must be clearly and accurately communicated to avoid misunderstanding of the dose time in relation to the collection time. Miscommunication between the individual administering the medication and the individual collecting the specimen is the most frequent cause of subtherapeutic levels, toxic levels, and misleading information used in the calculation of future doses. Some pharmacies use a computerized pharmacokinetics approach to dosing that eliminates the need to be concerned about peak and trough collections; random specimens are adequate. If administration of the drug is delayed, notify the appropriate department(s) to reschedule the blood draw and notify the requesting health-care provider (HCP) if the delay has caused any real or perceived therapeutic harm.

This procedure is contraindicated for: N/A

INDICATIONS

Cyclosporine, Sirolimus, Tacrolimus

- Assist in the management of treatments to prevent organ rejection
- Monitor for toxicity

Everolimus

- Assist in the management of treatments to prevent organ rejection
- Assist in the management of treatments for subependymal giant cell astrocytoma
- Monitor effectiveness of treatment of renal cell carcinoma
- Monitor for toxicity

Methotrexate

- Monitor effectiveness of treatment of cancer and some autoimmune disorders
- Monitor for toxicity

POTENTIAL DIAGNOSIS

Level	Response
Normal levels	Therapeutic effect
Toxic levels	Adjust dose as indicated
Cyclosporine	Renal impairment
Methotrexate	Renal impairment
Everolimus, sirolimus, tacrolimus	Hepatic impairment

CRITICAL FINDINGS

It is important to note the adverse effects of toxic and subtherapeutic levels. Care must be taken to investigate signs and symptoms of too little and too much medication.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms. It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding

may require completion of a notification form with review by Risk Management.

Cyclosporine: Greater Than 500 ng/mL (SI: Greater Than 416 nmol/L)

Signs and symptoms of cyclosporine toxicity include increased severity of expected side effects, which include nausea, stomatitis, vomiting, anorexia, hypertension, infection, fluid retention, hypercalcemic metabolic acidosis, tremor, seizures, headache, and flushing. Possible interventions include close monitoring of blood levels to make dosing adjustments, inducing emesis (if orally ingested), performing gastric lavage (if orally ingested), withholding the drug, and initiating alternative therapy for a short time until the patient is stabilized.

Methotrexate: Greater Than 1 micromol/L After 48 Hr With High-Dose Therapy; Greater Than 0.02 micromol/L After 48 Hr With Low-Dose Therapy

Signs and symptoms of methotrexate toxicity include increased severity of expected side effects, which include nausea, stomatitis, vomiting, anorexia, bleeding, infection, bone marrow depression, and, over a prolonged period of use, hepatotoxicity. The effect of methotrexate on normal cells can be reversed by administration of 5-formyltetrahydrofolate (citrovorum or leucovorin). 5-Formyltetrahydrofolate allows higher doses of methotrexate to be given.

Everolimus: Greater Than 15 ng/mL (SI: Greater than 15 mcg/L)

Signs and symptoms of everolimus pulmonary toxicity include hypoxia, pleural effusion, cough, and dyspnea. Possible interventions include dosing adjustments, administration of corticosteroids, and monitoring of pulmonary function with chest x-ray. Use of everolimus is contraindicated in patients with severe hepatic impairment. Concomitant administration of strong CYP3A4 inhibitors may significantly increase everolimus levels.

Sirolimus: Greater Than 25 ng/mL (SI: Greater than 25 mcg/L)

Signs and symptoms of sirolimus pulmonary toxicity include cough, shortness of breath, chest pain, and rapid heart rate. Possible interventions include dosing adjustments, administration of corticosteroids, and monitoring of pulmonary function with chest x-ray.

Tacrolimus: Greater Than 25 ng/mL (SI: Greater than 25 mcg/L)

Signs and symptoms of tacrolimus toxicity include tremors, seizures, headache, high blood pressure, hyperkalemia, tinnitus, nausea, and vomiting. Possible interventions include treatment of hypertension, administration of antiemetics for nausea and vomiting, and dosing adjustments.

INTERFERING FACTORS

- Numerous drugs interact with cyclosporine and either increase cyclosporine levels or increase the risk of toxicity. These drugs include acyclovir, aminoglycosides, amiodarone, amphotericin B, anabolic steroids, cephalosporins, cimetidine, danazol, erythromycin, furosemide, ketoconazole, melphalan, methylprednisolone, miconazole, NSAIDs, oral contraceptives, and trimethoprim-sulfamethoxazole.
- Drugs that may decrease cyclosporine levels include carbamazepine, ethotoin, mephenytoin, phenobarbital, phenytoin, primidone, and rifampin.
- Drugs that may increase methotrexate levels or increase the risk of toxicity include NSAIDs, probenecid, salicylate, and sulfonamides.
- Antibiotics may decrease the absorption of methotrexate.
- Drugs and foods that may increase everolimus levels include ketoconazole, amprenavir, aprepitant, atazanavir, clarithromycin, delavirdine, diltiazem, erythromycin, fluconazole, fosamprenavir, grapefruit juice, indinavir, itraconazole, nefazodone,

nelfinavir, ritonavir, saquinavir, telithromycin, verapamil, and voriconazole.

- Drugs and herbs that may decrease everolimus levels include carbamazepine, dexamethasone, phenobarbital, phenytoin, rifabutin, rifampin, and St. John's Wort.
- Drugs and foods that may increase sirolimus levels include bromocriptine, cimetidine, cisapride, clotrimazole, danazol, diltiazem, fluconazole, indinavir, metoclopramide, nifedipine, ritonavir, troleandomycin, and verapamil.
- Drugs and herbs that may increase sirolimus levels include carbamazepine, phenobarbital, phenytoin, rifampentine, and St. John's Wort.
- Drugs and foods that may increase tacrolimus levels include bromocriptine, chloramphenicol, cimetidine, cisapride, clarithromycin, clotrimazole, cyclosporine, danazol, diltiazem, erythromycin, fluconazole, grapefruit juice, itraconazole, ketoconazole, methylprednisolone, metoclopramide, nelfinavir, nifedipine, torinavir, troleandomycin, verapamil, and voriconazole.
- Drugs and herbs that may decrease tacrolimus levels include carbamazepine, ethotoin, mephenytoin, octreotide, phenobarbital, primidone, rifabutin, rifampin, sirolimus, and St. John's Wort.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assess in monitoring therapeutic and toxic drug levels.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary and immune systems,

symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Some considerations prior to medication administration include documentation of adequate renal function with creatinine and BUN levels, documentation of adequate hepatic function with alanine aminotransferase (ALT) and bilirubin levels, and documentation of adequate hematological and immune function with platelet and white blood cell (WBC) count. Patients receiving methotrexate must be well hydrated and, depending on the therapy, may be treated with sodium bicarbonate for urinary alkalization to enhance drug excretion. Leucovorin calcium rescue therapy may also be part of the protocol.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Note that lack of consideration for the proper collection time in relation to the dosing schedule can provide misleading information that may result in an erroneous interpretation of levels, creating the potential for a medication-error-related injury to the patient.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in

Appendix A. Consider recommended collection time in relation to the dosing schedule. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection, noting the last dose of medication taken. Perform a venipuncture.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Patients taking immunosuppressant therapy tend to have decreased appetites due to the side effects of the medication. Instruct patients to consume a variety of foods within the basic food groups, maintain a healthy weight, be physically active, limit salt intake, limit alcohol intake, and be a nonsmoker.
- ▶ Recognize anxiety related to test results, and offer support. Patients receiving these drugs usually have conditions that can be intermittently moderately to severely debilitating, resulting in significant lifestyle changes. Educate the patient regarding access to counseling services, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain to the patient the importance of following the medication regimen and give instructions regarding drug interactions. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient to be prepared to provide the pharmacist with a list of other medications he or she is already taking in the event that the requesting HCP prescribes a medication.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include ALT, AST, bilirubin, BUN, CBC platelet count, CBC WBC count and differential, and creatinine.
- Refer to the Genitourinary and Immune systems tables at the end of the book for related tests by body system.

Infectious Mononucleosis Screen

SYNONYM/ACRONYM: Monospot, heterophil antibody test, IM serology.

COMMON USE: To assess for Epstein-Barr virus and assist with diagnosis of infectious mononucleosis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum in a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method:Agglutination) Negative.

DESCRIPTION: Infectious mononucleosis is caused by the Epstein-Barr virus (EBV). The incubation period is 10 to 50 days, and the symptoms last 1 to 4 wk after the infection has fully developed. The hallmark of EBV infection is the presence of heterophil antibodies, also called Paul-Bunnell-Davidsohn antibodies, which are immunoglobulin M (IgM) antibodies that agglutinate sheep or horse red blood cells. The disease induces formation of abnormal lymphocytes in the lymph nodes; stimulates increased formation of heterophil antibodies; and is characterized by fever, cervical lymphadenopathy, tonsillopharyngitis, and hepatosplenomegaly. EBV is also thought to play a role in Burkitt's lymphoma, nasopharyngeal carcinoma, and chronic fatigue syndrome. If the results of the heterophil antibody screening test are negative and

infectious mononucleosis is highly suspected, EBV-specific serology should be requested.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in confirming infectious mononucleosis

POTENTIAL DIAGNOSIS*Positive findings in*

- Infectious mononucleosis

Negative findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- False-positive results may occur in the presence of narcotic

addiction, serum sickness, lymphomas, hepatitis, leukemia, cancer of the pancreas, and phenytoin therapy.

- A false-negative result may occur if treatment was begun before antibodies developed or if the test was done less than 6 days after exposure to the virus.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to Epstein-Barr viral infection secondary to exposure through kissing, cough, sneeze, sharing food utensils of an infected person</i>)	Fatigue, malaise, sore throat, fever, enlarged lymph nodes in the neck and armpits, swollen tonsils, headache, rash, swollen spleen	Rest, drink plenty of fluids (water and fruit juice), administer prescribed antibiotics to treat strep throat; administer prescribed steroids to treat swollen throat or tonsils; discuss gargling with warm saltwater to decrease pain of sore throat; discuss using over-the-counter ibuprofen or acetaminophen; discuss the importance of avoiding at-risk activities that may cause trauma and spleen rupture
Fatigue (<i>Related to Epstein-Barr viral infection secondary to exposure through kissing, cough, sneeze, sharing food utensils of an infected person</i>)	Decreased concentration; increased physical complaints; unable to restore energy with sleep; reports being tired; unable to maintain normal routine	Monitor and trend mononucleosis screening results; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia

(table continues on page 976)

Problem	Signs & Symptoms	Interventions
Knowledge (<i>Related to recent diagnosis; complexity of treatment; poor understanding of provided information; cultural or language barriers; anxiety; emotional disturbance; unfamiliarity with medical management</i>)	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management; verbalizes inaccurate information; lack of follow-through with directions	Identify patient's, family's, and significant others' concerns about disease process; discuss the importance of fluids and rest for recovery; discuss the importance of avoiding vigorous activities, heavy lifting, roughhousing, or contact sports for at least 1 mo or as recommended by the health-care provider (HCP)

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with diagnosing a mononucleosis infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex. Obtain a history of exposure.
- ▶ Obtain a history of the patient's hepatobiliary and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent therapies that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and inform the patient that signs and symptoms of infection include fever,

chills, sore throat, enlarged lymph nodes, and fatigue. Self-care while the disease runs its course include adequate fluid and nutritional intake along with sufficient rest. Activities that cause fatigue or stress should be avoided. Advise the patient to refrain from direct contact with others because the disease is transmitted through saliva.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Advise the patient to refrain from direct contact with others because the disease is transmitted through saliva. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Inform the patient that approximately 10% of all results are false-negative or false-positive.
- ▶ Inform the patient that signs and symptoms of infection include fever, chills, sore throat, enlarged lymph nodes, and fatigue.

- ▶ Emphasize the importance of self-care while the disease runs its course, which includes adequate fluid and nutritional intake along with sufficient rest.

Expected Patient Outcomes:

Knowledge

- ▶ Verbalizes understanding of how to pace activities to conserve energy and manage fatigue in relation to activities of daily living
- ▶ States the importance of lengthy rest periods for recovery from mononucleosis

Skills

- ▶ Follows the recommendation to increase fluid intake (water and juice)
- ▶ Follows the recommendation to take over-the-counter ibuprofen or acetaminophen for comfort as needed

Attitude

- ▶ Complies with the request to get plenty of rest to facilitate the recovery process
- ▶ Complies with the recommendation to avoid kissing to prevent infection of another individual with mononucleosis

RELATED MONOGRAPHS:

- ▶ Related tests include CBC with peripheral blood smear evaluation and US abdomen.
- ▶ Refer to the Hepatobiliary and Immune systems tables at the end of the book for related tests by body system.

Insulin and Insulin Response to Glucose

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess the amount of insulin secreted in response to blood glucose to assist in diagnosis of types of hypoglycemia and insulin-resistant pathologies.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

75-g Glucose Load	Insulin	SI Units (Conventional Units × 6.945)	Tolerance for Glucose (Hypoglycemia)
Fasting	Less than 17 micro international units/L	Less than 118.1 pmol/L	Less than 110 mg/dL
30 min	6–86 micro international units/L	41.7–597.3 pmol/L	Less than 200 mg/dL
1 hr	8–118 micro international units/L	55.6–819.5 pmol/L	Less than 200 mg/dL
2 hr	5–55 micro international units/L	34.7–382 pmol/L	Less than 140 mg/dL
3 hr	Less than 25 micro international units/L	Less than 174 pmol/L	65–120 mg/dL
4 hr	Less than 15 micro international units/L	Less than 104.2 pmol/L	65–120 mg/dL
5 hr	Less than 8 micro international units/L	Less than 55.6 pmol/L	65–115 mg/dL

DESCRIPTION: Insulin is a hormone secreted by the beta cells of the islets of Langerhans in the pancreas in response to elevated blood glucose levels. Its overall effect is to help regulate the metabolism of glucose. Specifically, insulin decreases blood levels of glucose by promoting transport of glucose into the liver and muscles to be stored as glycogen. Insulin also participates in regulation of the processes required for metabolism of fats, carbohydrates, and proteins. The insulin response test measures insulin response to a standardized dose of glucose, administered over fixed period of time and is useful in evaluating patients with hypoglycemia and suspected insulin-resistance.

relation to blood glucose levels (best shown with glucose tolerance tests or 2-hr postprandial tests)

- Assist in the diagnosis of insulinoma, as indicated by sustained high levels of insulin and absence of blood glucose-related variations
- Confirm functional hypoglycemia, as indicated by circulating insulin levels appropriate to changing blood glucose levels
- Differentiate between insulin-resistant diabetes, in which insulin levels are high, and non-insulin-resistant diabetes, in which insulin levels are low
- Evaluate fasting hypoglycemia of unknown cause
- Evaluate postprandial hypoglycemia of unknown cause
- Evaluate uncontrolled insulin-dependent (type 1) diabetes

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of early or developing non-insulin-dependent (type 2) diabetes, as indicated by excessive production of insulin in

POTENTIAL DIAGNOSIS

Increased in

- Acromegaly (*related to excess production of growth hormone, which increases insulin levels*)
- Alcohol use (*related to stimulation of insulin production*)

- Cushing's syndrome (*related to overproduction of cortisol, which increases insulin levels*)
- Excessive administration of insulin
- Insulin- and proinsulin-secreting tumors (insulinomas)
- Obesity (*related to development of insulin resistance; body does not respond to insulin being produced*)
- Persistent hyperinsulinemic hypoglycemia (*collection of hypoglycemic disorders of infants and children*)
- Reactive hypoglycemia in developing diabetes
- Severe liver disease

Decreased in

- Beta cell failure (*pancreatic beta cells produce insulin; therefore, damage to these cells will decrease insulin levels*)
- Insulin-dependent diabetes (*related to lack of endogenous insulin*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that may increase insulin levels include acetohexamide, albuterol, amino acids, beclomethasone, betamethasone, broxaterol, calcium gluconate, cannabis, chlorpropamide, glibornuride, glipizide, glisoxepide, glucagon, glyburide, ibopamine, insulin, oral contraceptives, pancreozymin, prednisolone, prednisone, rifampin, terbuthaline, tolazamide, tolbutamide, trichlor-methiazide, and verapamil.
- Drugs that may decrease insulin levels include acarbose, calcitonin, cimetidine, clofibrate, dexfenfluramine, diltiazem, doxazosin, enalapril, enprostil, ether, hydroxypropyl methylcellulose, metformin (Glucophage), niacin, nifedipine, nitrendipine, octreotide, phenytoin, propranolol, and psyllium.

- Administration of insulin or oral hypoglycemic agents within 8 hr of the test can lead to falsely elevated levels.
- Hemodialysis destroys insulin and affects test results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in the evaluation of low blood sugar.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ If a single sample is to be collected, the patient should have fasted and refrained, with medical direction, from taking insulin or other oral hypoglycemic agents for at least 8 hr before specimen collection. Protocols may vary among facilities.

▶ **Hypoglycemia:** Serial specimens for insulin levels are collected in conjunction with glucose levels after administration of a 75-g glucose load. The patient should be prepared as for a standard oral glucose tolerance test over a 5-hr period. Protocols may vary among facilities.

▶ Note that there are no fluid restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Note that the patient may have difficulty drinking the extremely sweet glucose beverage and become nauseous.

▶ Ensure that the patient has complied with dietary and medication restrictions and other pretesting preparations; assure that food or medications have been restricted as instructed prior to the specific procedure's protocol.

▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.

▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.

▶ Instruct the patient to resume usual diet and medication, as directed by the HCP.

▶ **Nutritional Considerations:** There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) with the appropriate HCPs, particularly professionals trained in nutrition.

▶ Note that abnormal insulin response and impaired glucose tolerance may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).

▶ **Social and Cultural Considerations:** Numerous studies point to the prevalence of excess body weight in American children and adolescents.

Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight control education.

- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, if indicated, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org), the American Heart Association (www.americanheart.org), or the NHLBI (www.nhlbi.nih.gov).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient in the use of home test kits approved by the U.S. Food and Drug Administration, if prescribed. Answer any questions or address any

concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. The American Diabetes Association (ADA) recommends A1C testing 4 times a year for insulin-dependent type 1 or type 2 diabetes and twice a year for non-insulin-dependent type 2 diabetes. The ADA also recommends that testing for diabetes commence at age 45 for asymptomatic individuals and continue every 3 yr in the absence of symptoms. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, ALT, angiography adrenal, bilirubin, BUN, calcium, catecholamines, cholesterol (HDL, LDL, total), cortisol, C-peptide, DHEA, creatinine, fecal analysis, fecal fat, fructosamine, GGT, gastric emptying scan, glucagon, glucose, GTT, glycated hemoglobin, GH, HVA, insulin antibodies, ketones, lipoprotein electrophoresis, metanephrines, microalbumin, and myoglobin.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Insulin Antibodies

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in the prediction, diagnosis, and management of type 1 diabetes as well as insulin resistance and insulin allergy.

SPECIMEN: Serum (1 mL) collected in a red-top tube.

NORMAL FINDINGS: (Method: Radioimmunoassay) Less than 0.4 Units/mL.

DESCRIPTION: The onset of Type I diabetes has been shown to correspond to the development of a number of autoantibodies. The most common anti-insulin antibody is immunoglobulin (Ig) G, but IgA, IgM, IgD, and IgE antibodies also have anti-insulin properties. IgM is thought to participate in insulin resistance and IgE in insulin allergy. Increased use of human insulin instead of purified animal insulin has resulted in a significant decrease in the incidence of insulin antibody formation as a result of treatment for diabetics using insulin. The presence of insulin antibodies has been demonstrated to be a strong predictor for development of Type I diabetes in individuals who do not have diabetes but are genetically predisposed.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in confirming insulin resistance
- Assist in determining if hypoglycemia is caused by insulin abuse
- Assist in determining insulin allergy

POTENTIAL DIAGNOSIS

Increased in

- Factitious hypoglycemia (**assists in differentiating lack of response due to the presence of insulin antibodies from secretive self-administration of insulin**)
- Insulin allergy or resistance (**antibodies bind to insulin and decrease amount of free insulin available for glucose metabolism**)
- Polyendocrine autoimmune syndromes

- Steroid-induced diabetes (**a side effect of treatment for systemic lupus erythematosus**)

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in the diagnosis and management of type 1 diabetes.
- ▶ Obtain a history of the patient's complaints, including a list of known allergies, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet and medication, as directed by the HCP.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with diabetes. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline empha-

- sizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, if indicated, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org) or the American Heart Association (www.americanheart.org).
 - ▶ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
 - ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor

progression of the disease process and determine the need for a change in therapy. The American Diabetes Association (ADA) recommends A1C testing 4 times a year for insulin-dependent type 1 or type 2 diabetes and twice a year for non-insulin-dependent type 2 diabetes. The ADA also recommends that testing for diabetes commence at age 45 for asymptomatic individuals and continue every 3 yr in the absence of symptoms.

Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include C-peptide, glucose, GTT, glycated hemoglobin, and insulin.
- ▶ Refer to the Endocrine and Immune systems tables at the end of the book for related tests by body system.

Intraocular Muscle Function

SYNONYM/ACRONYM: IOM function.

COMMON USE: To assess the function of the extraocular muscle to assist with diagnosis of strabismus, amblyopia, and other ocular disorders.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: Evaluation of ocular motility is performed to detect and measure muscle imbalance in conditions classified as heterophorias or heterotropias. This evaluation is performed in a manner to assess fixation of each eye, alignment of both eyes in all directions, and the ability of both eyes to work together binocularly. Heterophorias are latent ocular deviations kept in check by the binocular power of fusion and made intermittent by disrupting fusion. Heterotropias are conditions that manifest constant ocular deviations. The prefixes *eso-* (tendency for the eye to turn in), *exo-* (tendency for the eye to turn out), and *hyper-* (tendency for one eye to turn up) indicate the direction in which the affected eye moves spontaneously. *Strabismus* is the failure of both eyes to spontaneously fixate on the same

object because of a muscular imbalance (crossed eyes). *Amblyopia*, or lazy eye, is a term used for loss of vision in one or both eyes that cannot be attributed to an organic pathological condition of the eye or optic nerve. There are six extraocular muscles in each eye; their movement is controlled by three nerves. The actions of the muscles vary depending on the position of the eye when they become innervated. The cover test is commonly used because it is reliable, easy to perform, and does not require special equipment. The cover test method is described in this monograph. Another method for evaluation of ocular muscle function is the corneal light reflex test. It is useful with patients who cannot cooperate for prism cover testing or for patients who have poor fixation.

This procedure is contraindicated for: N/A

INDICATIONS

- Detection and evaluation of extra-ocular muscle imbalance

POTENTIAL DIAGNOSIS

The examiner should determine the range of ocular movements in all gaze positions, usually to include up and out, in, down and out, up and in, down and in, and out. Limited movements in gaze position can be recorded semiquantitatively as -1 (minimal), -2 (moderate), -3 (severe), or -4 (total).

Normal findings in

- Normal range of ocular movements in all gaze positions.

Abnormal findings in

- Amblyopia
- Heterophorias
- Heterotropias
- Strabismus

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to cooperate and remain still during the test because of age, significant pain, or mental status may interfere with the test results.
- Rubbing or squeezing the eyes may affect results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating eye muscle function.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens.
- ▶ Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- ▶ Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that a health-care provider (HCP) performs the test in a quiet room and that to evaluate both eyes, the test can take 2 to 4 min.
- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Note that one eye is tested at a time. The patient is given a fixation point, usually the testing personnel's index finger. An object, such as a small toy, can be used to ensure fixation in pediatric patients. The patient is asked to follow the fixation point with his or her gaze in the direction the fixation point

moves. When testing is completed, the procedure is repeated using the other eye. The procedure is performed at a distance and near, first with and then without corrective lenses. The examiner should determine the range of ocular movements in all gaze positions, usually to include up and out, in, down and out, up and in, down and in, and out.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss, anticipated loss of driving privileges, or the possibility of requiring corrective lenses (self-image).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Educate the patient, as appropriate, that he or she may be referred for special therapy to correct the anomaly, which may include glasses, prisms, eye exercises, eye patches, or chemical patching with drugs that modify the

focusing power of the eye. The patient and family should be educated that the chosen therapy involves a process of mental retraining. The mode of therapy in itself does not correct vision.

It is the process by which the brain becomes readapted to accept, receive, and store visual images received by the eye that results in vision correction. Therefore, the patient must be prepared to be alert, cooperative, and properly motivated. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include refraction and slit-lamp biomicroscopy.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Intraocular Pressure

SYNONYM/ACRONYM: IOP.

COMMON USE: To evaluate changes in ocular pressure to assist in diagnosis of disorders such as glaucoma.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: The intraocular pressure (IOP) of the eye depends on a number of factors.

The two most significant are the amount of aqueous humor present in the eye and the

circumstances by which it leaves the eye. Other physiological variables that affect IOP include respiration, pulse, and the degree of hydration of the body. Individual eyes respond to IOP differently. Some can tolerate high pressures (20 to 30 mm Hg), and some will incur optic nerve damage at lower pressures. With respiration, variations of up to 4 mm Hg in IOP can occur, and changes of 1 to 2 mm Hg occur with every pulsation of the central retinal artery. IOP is measured with a tonometer; normal values indicate the pressure at which no damage is done to the intraocular contents. The rate of fluid leaving the eye, or its ability to leave the eye unimpeded, is the most important factor regulating IOP. There are three primary conditions that result in occlusion of the outflow channels for fluid. The most common condition is open-angle glaucoma, in which the diameter of the openings of the trabecular meshwork becomes narrowed, resulting in an increased IOP due to an increased resistance of fluid moving out of the eye. In secondary or angle closure glaucoma, the trabecular meshwork becomes occluded by tumor cells, pigment, red blood cells in hyphema, or other material. Additionally, the obstructing material may cover parts of the meshwork itself, as with scar tissue or other types of adhesions that form after severe iritis, an angle-closure glaucoma attack, or a central retinal vein occlusion. The third condition impeding fluid outflow in the trabecular channels occurs with pupillary

block, most commonly associated with primary angle-closure glaucoma. In eyes predisposed to this condition, dilation of the pupil causes the iris to fold up like an accordion against the narrow-angle structures of the eye. Fluid in the posterior chamber has difficulty circulating into the anterior chamber; therefore, pressure in the posterior chamber increases, causing the iris to bow forward and obstruct the outflow channels even more. Angle-closure attacks occur quite suddenly and therefore do not give the eye a chance to adjust itself to the sudden increase in pressure. The eye becomes very red, the cornea edematous (patient may report seeing halos), and the pupil fixed and dilated, accompanied by a complaint of moderate pain. Pupil dilation can be initiated by emotional arousal or fear, conditions in which the eye must adapt to darkness (movie theaters), or mydriatics. Angle-closure glaucoma is an ocular emergency resolved by a peripheral iridectomy to allow movement of fluid between the anterior and posterior chambers. This procedure constitutes removal of a portion of the peripheral iris either by surgery or by use of an argon or yttrium-aluminum-garnet (YAG) laser.

This procedure is contraindicated for: N/A

INDICATIONS

- Diagnosis or ongoing monitoring of glaucoma

- Screening test included in a routine eye examination

POTENTIAL DIAGNOSIS

Normal findings in

- Normal IOP is between 13 and 22 mm Hg

Abnormal findings in

- Open-angle glaucoma
- Primary angle-closure glaucoma
- Secondary glaucoma

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Inability of the patient to remain still and cooperative during the test may interfere with the test results.
- Rubbing or squeezing the eyes may affect results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in measuring eye pressure.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex or topical anesthetic eyedrops.
- ▶ Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.

- ▶ Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Explain that the patient will be requested to fixate the eyes during the procedure. Address concerns about pain and explain that he or she may feel coldness or a slight sting when the anesthetic/fluorescein drops are instilled at the beginning of the procedure but that no discomfort will be experienced during the test. Instruct the patient as to what should be expected with the use of the tonometer. The patient will experience less anxiety if he or she understands that the tonometer tip will touch the tear film and not the eye directly. Inform the patient that a health-care provider (HCP) performs the test in a quiet, darkened room and that to evaluate both eyes, the test can take 1 to 3 min.
- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because any movement, such as coughing, breath-holding, or wandering eye movements, produces unreliable results.

- ▶ Seat the patient comfortably. Instruct the patient to look at directed target while the eyes are examined.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instill ordered topical anesthetic/fluorescein drops in each eye, as ordered, and allow time for it to work. Topical anesthetic/fluorescein drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (gray, semitransparent area of the eyeball where the cornea and sclera meet). Neither dropper nor bottle should touch the eyelashes.
- ▶ Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- ▶ A number of techniques are used to measure IOP. It can be measured at the slit lamp or with a miniaturized, handheld applanation tonometer or an airpuff tonometer.
- ▶ When the applanation tonometer is positioned on the patient's cornea, the instrument's headrest is placed against the patient's forehead. The tonometer should be held at an angle with the handle slanted away from the patient's nose. The tonometer tip should not touch the eyelids.
- ▶ When the tip is properly aligned and in contact with the fluorescein-stained tear film, force is applied to the tip using an adjustment control to the desired endpoint. The tonometer is removed from the eye. The reading is taken a second time, and if the pressure is elevated, a third reading is taken. The procedure is repeated on the other eye.
- ▶ With the airpuff tonometer, an air pump blows air onto the cornea, and the time it takes for the air puff to flatten the cornea is detected by infrared light and photoelectric cells. This time is directly related to the IOP.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss or anticipated loss of driving privileges. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the Glaucoma Research Foundation (www.glaucoma.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications, usually eyedrops, that are intended to decrease IOP. Explain the importance of adhering to the therapy regimen, especially since increased IOP does not present symptoms. Instruct the patient in both the ocular side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include fundus photography, gonioscopy, nerve fiber analysis, pachymetry, slit-lamp biomicroscopy, and visual field testing.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Intravenous Pyelography

SYNONYM/ACRONYM: Antegrade pyelography, excretory urography (EUG), intravenous urography (IVU, IUG), IVP.

COMMON USE: To assess urinary tract dysfunction or evaluate progression of renal disease such as stones, bleeding, and congenital anomalies.

AREA OF APPLICATION: Kidneys, ureters, bladder, and renal pelvis.

CONTRAST: IV radiopaque iodine-based contrast medium.

DESCRIPTION: Intravenous pyelography (IVP) is most commonly performed to determine urinary tract dysfunction or renal disease. IVP uses IV radiopaque contrast medium to visualize the kidneys, ureters, bladder, and renal pelvis. The contrast medium concentrates in the blood and is filtered out by the glomeruli passing out through the renal tubules and concentrated in the urine. Renal function is reflected by the length of time it takes the contrast medium to appear and to be excreted by each kidney. A series of images is performed during a 30-min period to view passage of the contrast through the kidneys and ureters into the bladder. Tomography may be employed during the IVP to permit the examination of an individual layer or plane of the organ that may be obscured by surrounding overlying structures. Many facilities have replaced the IVP with computed tomography (CT) studies. CT provides better detail of the anatomical structures in the urinary system and therefore greater sensitivity in identification of renal pathology.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate

to severe reactions to ionic contrast medium.

-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic**
-  Elderly and compromised patients who are chronically dehydrated before the test, **because of their risk of contrast-induced renal failure.**
-  Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**

INDICATIONS

- Aid in the diagnosis of renovascular hypertension
- Evaluate the cause of blood in the urine
- Evaluate the effects of urinary system trauma
- Evaluate function of the kidneys, ureters, and bladder
- Evaluate known or suspected ureteral obstruction
- Evaluate the presence of renal, ureter, or bladder calculi
- Evaluate space-occupying lesions or congenital anomalies of the urinary system

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size and shape of kidneys, ureters, and bladder
- Normal bladder and absence of masses or renal calculi, with prompt visualization of contrast medium through the urinary system

Abnormal findings in

- Absence of a kidney (congenital malformation)
- Benign and malignant kidney tumors
- Bladder tumors

- Congenital renal or urinary tract abnormalities
- Glomerulonephritis
- Hydronephrosis
- Prostatic enlargement
- Pyelonephritis
- Renal cysts
- Renal hematomas
- Renal or ureteral calculi
- Soft tissue masses
- Tumors of the collecting system

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging**

Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation over-exposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the kidneys, ureters, and bladder.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Ensure that the results of blood tests, especially BUN and creatinine, are obtained and recorded before the procedure.
- ▶ Note any recent barium or other radiological contrast procedures. Ensure that barium studies were performed more than 4 days before the IVP.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Note the last time and dose of medication taken.

- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**

- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a radiology department by an HCP and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to take a laxative or a cathartic, as ordered, on the evening before the examination.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- ▶ Allergic reaction to contrast media is a potential complication.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.

- ▶ Assess for completion of bowel preparation according to the institution's procedure. Administer enemas or suppositories on the morning of the test, as ordered.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table.
- ▶ A kidney, ureter, and bladder (KUB) or plain film is taken to ensure that no barium or stool obscures visualization of the urinary system.
- ▶ Insert an IV line, if one is not already in place, and inject the contrast medium.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Images are taken at 1, 5, 10, 15, 20, and 30 min following injection of the contrast medium into the urinary system. Instruct the patient to exhale deeply and to hold his or her breath while each image is taken.
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Instruct the patient to void if a post-voiding exposure is required to visualize the empty bladder.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed if contrast was used.
- ▶ Observe for delayed reaction to iodinated contrast medium, including rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Monitor urinary output after the procedure. Decreased urine output may indicate impending renal failure.
- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bladder, biopsy kidney, biopsy prostate, BUN, CT abdomen, CT pelvis, creatinine, cystometry, cystoscopy, gallium scan, KUB, MRI abdomen, renogram, retrograde ureteropyelography, US abdomen, US bladder, US kidney, US prostate, urine markers of bladder cancer, urinalysis, urine cytology, and voiding cystourethrography.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

Intrinsic Factor Antibodies

SYNONYM/ACRONYM: IF antibodies, intrinsic factor blocking antibodies.

COMMON USE: To assist in the investigation of suspected pernicious anemia.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Immunoassay) Negative.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in
Conditions that involve the production of these blocking and binding autoantibodies

- Megaloblastic anemia
- Pernicious anemia
- Some patients with hyperthyroidism
- Some patients with insulin-dependent (type 1) diabetes

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Iron

SYNONYM/ACRONYM: Fe.

COMMON USE: To monitor and assess blood iron levels related to treatment, blood loss, metabolism, anemia, and storage disorders.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.179)
Newborn	100–250 mcg/dL	17.9–44.8 micromol/L
Infant–9 yr	20–105 mcg/dL	3.6–18.8 micromol/L
10–14 yr	20–145 mcg/dL	3.6–26 micromol/L
Adult		
Male	65–175 mcg/dL	11.6–31.3 micromol/L
Female	50–170 mcg/dL	9–30.4 micromol/L

Values tend to decrease in older adults.

DESCRIPTION: Iron plays a principal role in erythropoiesis, the formation and maturation of red blood cells (RBCs), and is required for hemoglobin (Hgb) synthesis. The human body contains between 4 and 5 grams of iron, about 65% of which is present in hemoglobin and 3% of which is present in myoglobin, the oxygen storage protein found in skeletal and cardiac muscle. A small amount is also found in cellular enzymes that catalyze the oxidation and reduction of iron. Excess iron is stored in the liver and spleen as ferritin and hemosiderin. Any iron present in the serum is in transit between the alimentary tract, the bone marrow, and available iron storage forms. Sixty to seventy percent of the body's iron is carried by its specific transport protein, transferrin. Normally, iron enters the body by oral ingestion; only 10% is absorbed, but as much as 20–30% can be absorbed in patients with iron-deficiency anemia. Unbound iron is highly toxic, but there is generally an excess of transferrin available to prevent the buildup of unbound iron in the circulation. Iron overload is as clinically significant as iron deficiency. An example of acute iron overload is the accidental poisoning of children caused by excessive intake of iron-containing multivitamins. Chronic iron overload can occur in patients receiving serial therapeutic transfusions of red blood cells over time for treatment of various cancers, hemoglobinopathies such as sickle cell anemia, the thalassemias, and other hemolytic anemias.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of blood loss, as evidenced by decreased serum iron
- Assist in the diagnosis of hemochromatosis or other disorders of iron metabolism and storage
- Determine the differential diagnosis of anemia
- Determine the presence of disorders that involve diminished protein synthesis or defects in iron absorption
- Evaluate accidental iron poisoning
- Evaluate iron overload in dialysis patients or patients with transfusion-dependent anemias
- Evaluate thalassemia and sideroblastic anemia
- Monitor hematological responses during pregnancy, when serum iron is usually decreased
- Monitor response to treatment for anemia

POTENTIAL DIAGNOSIS

Increased in

- Acute iron poisoning (children) *(related to excessive intake)*
- Acute leukemia
- Acute liver disease *(possibly related to decrease in synthesis of iron storage proteins by damaged liver; iron accumulates and levels increase)*
- Aplastic anemia *(related to repeated blood transfusions)*
- Excessive iron therapy *(related to excessive intake)*
- Hemochromatosis *(inherited disorder of iron overload; the iron is not excreted in proportion to the rate of accumulation)*
- Hemolytic anemias *(related to release of iron from lysed RBCs)*

- Lead toxicity (*lead can biologically mimic iron, displace it, and release it into circulation where its concentration increases*)
- Nephritis (*related to decreased renal excretion; accumulation in blood*)
- Pernicious anemias (PA) (*achlorhydria associated with PA prevents absorption of dietary iron, and it accumulates in the blood*)
- Sideroblastic anemias (*enzyme disorder prevents iron from being incorporated into Hgb, and it accumulates in the blood*)
- Thalassemia (*treatment for some types of thalassemia include blood transfusions, which can lead to iron overload*)
- Transfusions (repeated)
- Vitamin B₆ deficiency (*this vitamin is essential to Hgb formation; deficiency prevents iron from being incorporated into Hgb, and it accumulates in the blood*)
- Pregnancy (*related to depletion of iron stores by developing fetus*)
- Protein malnutrition (kwashiorkor) (*protein is required to form transport proteins, RBCs, and Hgb*)

CRITICAL FINDINGS

- Mild toxicity: greater than 350 mcg/dL (SI: greater than 62.6 micromol/L)
- Serious toxicity: greater than 400 mcg/dL (SI: greater than 71.6 micromol/L)
- Lethal: greater than 1,000 mcg/dL (SI: greater than 179 micromol/L)

Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms. Intervention may include chelation therapy by administration of deferoxamine mesylate (Desferal). It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Decreased in

- Acute and chronic infection (*iron is a nutrient for invading organisms*)
- Carcinoma (*related to depletion of iron stores*)
- Chronic blood loss (gastrointestinal, uterine) (*blood contains iron incorporated in Hgb*)
- Dietary deficiency
- Hypothyroidism (*pathophysiology is unclear*)
- Intestinal malabsorption
- Iron-deficiency anemia (*related to depletion of iron stores*)
- Nephrosis (*anemia is common in people with kidney disease; fewer RBCs are made because of a deficiency of erythropoietin related to the damaged kidneys, blood can be lost in dialysis, and iron intake may be lower due to lack of appetite*)
- Postoperative state

INTERFERING FACTORS

- Drugs that may increase iron levels include blood transfusions, chemotherapy drugs, iron (intramuscular), iron dextran, iron-protein-succinylate, methimazole, methotrexate, oral contraceptives, and rifampin.
- Drugs that may decrease iron levels include acetylsalicylic acid, allopurinol, cholestyramine, corticotropin, cortisone, deferoxamine, and metformin.
- Gross hemolysis can interfere with test results.
- Failure to withhold iron-containing medications 24 hr before the test may falsely increase values.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE**Potential Nursing Problems:**

Problem	Signs & Symptoms	Interventions
Fatigue (<i>Related to decreased oxygenation associated with unhealthy red blood cells secondary to inadequate iron</i>)	Verbalization of fatigue; altered ability to perform activities of daily living due to lack of energy; shortness of breath with exertion; increasingly frequent rest periods; presence of fatigue after sleep; inability to adhere to daily routine; altered level of concentration; complaints of tiredness	Monitor and trend CBC, HGB, HCT, iron; monitor for shortness of breath; administer oxygen and use pulse oximetry as appropriate; assess ability to perform self-care; assess nutritional intake of iron-rich foods; encourage frequent rest periods; teach techniques for conserving energy expenditure; administer blood and blood products as ordered; administer prescribed iron supplements; monitor urine, stool, and sputum for bleeding; assess for medical or psychological factors contributing to fatigue; prioritize and bundle activities to conserve energy and decrease fatigue
Tissue perfusion (cerebral, peripheral, renal) (<i>Related to inadequate cellular oxygen associated with unhealthy red blood cells secondary to iron deficiency</i>)	Confusion; altered mental status; headaches; dizziness; visual disturbances; hypotension; dizziness; cool extremities; capillary refill greater than 3 sec; weak pedal pulses; altered	Monitor blood pressure; assess for dizziness; check skin temperature for warmth; assess capillary refill; assess pedal pulses; monitor level of consciousness; monitor urine output to be in excess of 30 mL/hr; ensure adequate fluid intake or administer intravenous fluids as ordered; administer prescribed iron supplements

(table continues on page 998)

Problem	Signs & Symptoms	Interventions
	level of consciousness; decreased urine output	
Nutrition (<i>Related to inability to digest foods, metabolize foods, ingest foods; refusal to eat; increased metabolic needs associated with disease process; lack of understanding; unable to obtain healthy iron-rich foods</i>)	Unintended weight loss; current weight is 20% below ideal weight; pale dry skin; dry mucous membranes; documented inadequate caloric intake; subcutaneous tissue loss; hair pulls out easily; paresthesia	Record accurate daily weight at the same time each day with the same scale; obtain an accurate nutritional history; assess attitude toward eating; promote a dietary consult to evaluate current eating habits and best method of nutritional supplementation focusing on iron-rich foods; develop short- and long-term eating strategies; monitor serum iron; assess swallowing ability; encourage iron-rich cultural home foods; provide a pleasant environment for eating; alter food seasoning to enhance flavor; provide parenteral or enteral nutrition as prescribed
Bleeding loss (<i>Related to heavy menses; disease process with chronic blood loss [GI ulcer, malignancy]; overuse of NSAIDs</i>)	Altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; decreased serum iron; capillary refill greater than 3 sec; cool extremities; poor dietary selections	Monitor serum iron; increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; assess for disease process that may contribute to chronic blood loss; administer prescribed iron; assess stool for blood; consider dietary consult to support changed dietary selections; assess diet for iron-rich foods, and foods that inhibit absorption of iron

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating the amount of iron in the blood.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal and hematopoietic systems, symptoms, and results of previously

performed laboratory tests and diagnostic and surgical procedures.

- ▶ Note any recent therapies that can interfere with test results. Specimen collection should be delayed for several days after blood transfusion.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for at least 12 hr before testing and, with medical direction, to refrain from taking iron-containing medicines before specimen collection. Protocols may vary among facilities.
- ▶ Note that there are no fluid restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary and medication restrictions; ensure that food has been restricted for at least 12 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop

bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, or activity, as directed by the HCP.
- ▶ **Nutritional Considerations:** Educate the patient with abnormally elevated iron values, as appropriate, on the importance of reading food labels. Foods high in iron include meats (especially liver), eggs, grains, and green leafy vegetables. It is also important to explain that iron levels in foods can be increased if foods are cooked in cookware containing iron.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Patients must be educated to either increase or avoid intake of iron and iron-rich foods depending on their specific condition; for example, a patient with hemochromatosis or acute pernicious anemia should be educated to avoid foods rich in iron.
- ▶ Explain to the patient that the consumption of large amounts of alcohol damages the intestine and allows for the increased absorption of iron.
- ▶ Educate the patient that iron absorption is decreased by the absence (gastric resection) or diminished presence (use of antacids) of gastric acid.
- ▶ Teach the patient that phytic acids from cereals, tannins from tea and coffee, oxalic acid from vegetables, and minerals such as copper, zinc, and

manganese interfere with iron absorption.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family. Educate the patient regarding access to nutritional counseling services.
- ▶ Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).

Expected Patient Outcomes:

Knowledge

- ▶ Educate the patient with abnormal iron values that numerous factors affect the absorption of iron, enhancing or decreasing absorption regardless of the original content of the iron-containing dietary source.
- ▶ Teach patient that iron absorption after a meal is also increased by factors in meat, fish, and poultry, as well as a high intake of calcium and ascorbic acid.

Skills

- ▶ Demonstrates proficiency in taking ordered iron supplements in a manner that enhances absorption
- ▶ Demonstrates proficiency in selecting foods that are high in iron

Attitude

- ▶ Complies with recommended lifestyle changes to increase or decrease iron intake based on laboratory results
- ▶ Understands that a blood transfusion may be necessary to replace lost iron stores quickly to maintain health

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, biopsy liver, CBC, CBC RBC count, CBC RBC indices, CBC RBC morphology, CBC WBC count and differential, erythropoietin, ferritin, folate, FEP, gallium scan, hemosiderin, iron binding/transferrin, lead, porphyrins, reticulocyte count, and vitamin B₁₂.
- ▶ Refer to the Gastrointestinal and Hematopoietic systems tables at the end of the book for related tests by body system.

Iron-Binding Capacity (Total), Transferrin, and Iron Saturation

SYNONYM/ACRONYM: TIBC, Fe Sat.

COMMON USE: To monitor iron replacement therapy and assess blood iron levels to assist in diagnosing types of anemia such as iron deficiency.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Spectrophotometry for TIBC and nephelometry for transferrin)

Test	Conventional Units	SI Units
TIBC	250–350 mcg/dL	(Conventional Units \times 0.179) 45–63 micromol/L
Transferrin	215–380 mg/dL	(Conventional Units \times 0.01) 2.15–3.8 g/L
Iron saturation	20–50%	

TIBC = total iron-binding capacity.

DESCRIPTION: Iron plays a principal role in erythropoiesis, the formation and maturation of red blood cells (RBCs), and is required for hemoglobin (Hgb) synthesis. The human body contains between 4 and 5 grams of iron, about 65% of which is present in hemoglobin and 3% of which is present in myoglobin, the oxygen storage protein found in skeletal and cardiac muscle. A small amount is also found in cellular enzymes that catalyze the oxidation and reduction of iron. Excess iron is stored in the liver and spleen as ferritin and hemosiderin. Any iron present in the serum is in transit between the alimentary tract, the bone marrow, and available iron storage forms. Sixty to seventy percent of the body's iron is carried by its specific transport protein, transferrin. For this reason, total iron-binding capacity (TIBC) and transferrin are sometimes referred to interchangeably, even though other proteins carry iron and contribute to the TIBC. Unbound iron is highly toxic, but there is generally an excess of transferrin available to prevent the buildup of unbound iron in the circulation. The percentage of iron saturation is calculated by dividing the serum iron value by the TIBC value and multiplying by 100.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of iron-deficiency anemia
- Differentiate between iron-deficiency anemia and anemia secondary to chronic disease
- Monitor hematological response to therapy during pregnancy and iron-deficiency anemias
- Provide support for diagnosis of hemochromatosis or diseases of iron metabolism and storage

POTENTIAL DIAGNOSIS

Increased in

- Acute liver disease
- Hypochromic (iron-deficiency) anemias (*insufficient circulating iron levels to saturate binding sites*)
- Late pregnancy

Decreased in

- Chronic infections (*transferrin is a negative acute-phase reactant protein and during periods of inflammation will demonstrate decreased levels*)
- Cirrhosis (*transferrin is a negative acute-phase reactant protein and during periods of inflammation will demonstrate decreased levels*)
- Hemochromatosis (*occurs early in the disease as intestinal absorption of iron available for binding increases*)

- Hemolytic anemias (*transferrin becomes saturated, and the iron-binding capacity is significantly decreased*)
- Neoplastic diseases (*transferrin is a negative acute-phase reactant protein and during periods of inflammation will demonstrate decreased levels*)
- Protein depletion (*transferrin contributes to the total protein concentration and will reflect a decrease in protein depletion*)
- Renal disease (*transferrin is a negative acute-phase reactant protein and during periods of inflammation will demonstrate decreased levels*)
- Sideroblastic anemias (*transferrin becomes saturated, and the iron-binding capacity is significantly decreased*)
- Thalassemia (*transferrin becomes saturated, and the iron-binding capacity is significantly decreased*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase TIBC levels include mestranol and oral contraceptives.
- Drugs that may decrease TIBC levels include asparaginase, chloramphenicol, corticotropin, cortisone, and testosterone.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing anemia.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, biopsy liver, CBC, CBC RBC count, CBC RBC indices, CBC RBC morphology, CBC WBC count and differential, erythropoietin, ferritin, folate, FEP, gallium scan, hemosiderin, lead, porphyrins, reticulocyte count, and vitamin B₁₂.
- ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Ketones, Blood and Urine

SYNONYM/ACRONYM: Ketone bodies, acetoacetate, acetone.

COMMON USE: To investigate diabetes as the cause of ketoacidosis and monitor therapeutic interventions.

SPECIMEN: Serum (1 mL) collected from gold-, red-, or red/gray-top tube. Urine (5 mL), random or timed specimen, collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Colorimetric nitroprusside reaction) Negative.

DESCRIPTION: Ketone bodies refer to the three intermediate products of metabolism: acetone, acetoacetic acid, and β -hydroxybutyrate. Even though β -hydroxybutyrate is not a ketone, it is usually listed with the ketone bodies. In healthy individuals, ketones are produced and completely metabolized by the liver so that measurable amounts are not normally present in serum. Ketones appear in the urine before a significant serum level is detectable. If the patient has excessive fat metabolism, ketones are found in blood and urine. Excessive fat metabolism may occur if the patient has impaired ability to metabolize carbohydrates, inadequate carbohydrate intake, inadequate insulin levels, excessive carbohydrate loss, or increased carbohydrate demand. A strongly positive acetone result without severe acidosis, accompanied by normal glucose, electrolyte, and bicarbonate levels, is strongly suggestive of isopropyl alcohol poisoning. A low-carbohydrate or high-fat diet may cause a positive acetone test. Ketosis in people with diabetes is usually accompanied by increased glucose and decreased bicarbonate and pH. Extremely elevated levels of ketone bodies can result in coma. This situation

is particularly life threatening in children younger than 10 yr.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of starvation, stress, alcoholism, suspected isopropyl alcohol ingestion, glycogen storage disease, and other metabolic disorders
- Detect and monitor treatment of diabetic ketoacidosis
- Monitor the control of diabetes
- Screen for ketonuria due to acute illness or stress in nondiabetic patients
- Screen for ketonuria to assist in the assessment of inborn errors of metabolism
- Screen for ketonuria to assist in the diagnosis of suspected isopropyl alcohol poisoning

POTENTIAL DIAGNOSIS

Increased in

Ketones are generated in conditions that involve the metabolism of carbohydrates, fatty acids, and protein.

- Acidosis
- Branched-chain ketonuria
- Carbohydrate deficiency
- Eclampsia
- Fasting or starvation

- Gestational diabetes
- Glycogen storage diseases
- High-fat or high-protein diet
- Hyperglycemia
- Ketoacidosis of alcoholism and diabetes
- Illnesses with marked vomiting and diarrhea
- Isopropyl alcohol ingestion
- Methylmalonic aciduria
- Postanesthesia period
- Propionyl coenzyme A carboxylase deficiency

Decreased in: N/A

CRITICAL FINDINGS

- Strongly positive test results for glucose and ketones

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a

notification form with review by Risk Management.

Note and immediately report to the health-care provider (HCP) strongly positive results in urine and related symptoms. An elevated level of ketone bodies is evidenced by fruity-smelling breath, acidosis, ketonuria, and decreased level of consciousness. Administration of insulin and frequent blood glucose measurement may be indicated.

INTERFERING FACTORS

- Drugs that may cause an increase in serum ketone levels include acetylsalicylic acid (if therapy results in acidosis, especially in children), albuterol, fenfluramine, nifedipine, and rimiterol.
- Drugs that may cause a decrease in serum ketone levels include acetylsalicylic acid and valproic acid. Increases have been shown in hyperthyroid patients receiving propranolol and propylthiouracil.
- Drugs that may increase urine ketone levels include acetylsalicylic acid (if therapy results in acidosis, especially in children), ether, metformin, and niacin.
- Drugs that may decrease urine ketone levels include acetylsalicylic acid.
- Urine should be checked within 60 min of collection.
- Bacterial contamination of urine can cause false-negative results.
- Failure to keep reagent strip container tightly closed can cause false-negative results. Light and moisture affect the ability of the chemicals in the strip to perform as expected.
- False-negative or weakly false-positive test results can be obtained when β -hydroxybutyrate is the predominating ketone body in cases of lactic acidosis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing metabolic disorders such as diabetes.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that blood specimen collection takes approximately 5 to 10 min. The amount of time required to collect a urine specimen depends on the level of cooperation from the patient. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture as appropriate.

Blood

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Alternatively, a fingerstick or heel stick method of specimen collection can be used.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Urine

- ▶ Review the procedure with the patient. Explain to the patient how to collect a second-voided midstream void, then drink a glass of water, wait 30 min, and then try to void again.
- ▶ Instruct the patient to avoid excessive exercise and stress before specimen collection.

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Blood or Urine

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting HCP, who will discuss the results with the patient.

- ▶ **Nutritional Considerations:** Increased levels of ketone bodies may be associated with diabetes. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association. Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) with the appropriate HCPs, particularly professionals trained in nutrition.
- ▶ Impaired glucose tolerance may be associated with diabetes. Instruct the patient and caregiver to report signs and symptoms of hypoglycemia (weakness, confusion, diaphoresis, rapid pulse) or hyperglycemia (thirst, polyuria, hunger, lethargy).
- ▶ **Nutritional Considerations:** Increased levels of ketone bodies may be associated with poor carbohydrate

intake in an unbalanced diet; therefore, the body breaks down fat instead of carbohydrate for energy. Increasing carbohydrate intake in the patient’s diet reduces the levels of ketone bodies. Carbohydrates can be found in starches and sugars. Starch is a complex carbohydrate that can be found in foods such as grains (breads, cereals, pasta, rice) and starchy vegetables (corn, peas, potatoes). Sugar is a simple carbohydrate that can be found in natural foods (fruits and natural honey) and processed foods (desserts and candy).

- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Emphasize, if indicated, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org) or the American Heart Association (www.americanheart.org).
- ▶ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. The ADA recommends A1C testing 4 times a year for insulin-dependent type 1 or type 2 diabetes and twice a year for non-insulin-dependent type 2 diabetes. The ADA also recommends that testing for diabetes commence at age 45 for asymptomatic individuals and continue every 3 yr in the absence of symptoms. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

▶ Related tests include ACTH, angiography adrenal, anion gap, blood gases, BUN, calcium, catecholamines, cholesterol (HDL, LDL, total), cortisol, C-peptide, DHEA, electrolytes, fecal analysis, fecal fat, fluorescein angiography, fructosamine, fundus photography,

gastric emptying scan, GTT, glycated hemoglobin A_{1c}, HVA, insulin, insulin antibodies, lactic acid, lipoprotein electrophoresis, metanephrines, microalbumin, osmolality, phosphorus, UA, and visual fields test.

▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Kidney, Ureter, and Bladder Study

SYNONYM/ACRONYM: Flat plate of the abdomen, KUB, plain film of the abdomen.

COMMON USE: To visualize and assess the abdominal organs for obstruction or abnormality related to mass, trauma, bleeding, stones, or congenital anomaly.

AREA OF APPLICATION: Kidneys, ureters, bladder, and abdomen.

CONTRAST: None.

DESCRIPTION: A kidney, ureter, and bladder (KUB) x-ray examination provides information regarding the structure, size, and position of the abdominal organs; it also indicates whether there is any obstruction or abnormality of the abdomen caused by disease or congenital malformation. Calcifications of the renal calyces, renal pelvis, and any radiopaque calculi present in the urinary tract or surrounding organs may be visualized in addition to normal air and gas patterns within the intestinal tract. Perforation of the intestinal tract or an intestinal obstruction can be visualized on erect KUB images. KUB x-rays are among the first examinations done to diagnose intra-abdominal diseases such as intestinal obstruction, masses, tumors, ruptured organs,

abnormal gas accumulation, and ascites.

This procedure is contraindicated for

- ▶  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Determine the cause of acute abdominal pain or palpable mass
- Evaluate the effects of lower abdominal trauma, such as internal hemorrhage
- Evaluate known or suspected intestinal obstructions

- Evaluate the presence of renal, ureter, or other organ calculi
- Evaluate the size, shape, and position of the liver, kidneys, and spleen
- Evaluate suspected abnormal fluid, air, or metallic objects in the abdomen

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size and shape of kidneys
- Normal bladder, absence of masses and renal calculi, and no abnormal accumulation of air or fluid

Abnormal findings in

- Abnormal accumulation of bowel gas
- Ascites
- Bladder distention
- Congenital renal anomaly
- Hydronephrosis
- Intestinal obstruction
- Organomegaly
- Renal calculi
- Renal hematomas
- Ruptured viscus
- Soft tissue masses
- Trauma to liver, spleen, kidneys, and bladder
- Vascular calcification

CRITICAL FINDINGS

- Bowel obstruction
- Ischemic bowel
- Visceral injury

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP,

Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Improper adjustment of the radiographic equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study.
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined, for images done by portable equipment.
- Retained barium from a previous radiological procedure.

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding patients younger than 17. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign

can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the status of the abdomen.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that little to no pain is expected during the test, but there may be moments of discomfort. Inform the patient that the procedure is performed in the radiology department or at the bedside by a registered radiologic technologist and takes approximately 5 to 15 min to complete.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove all metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has removed all metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Place the patient on the table in a supine position with hands relaxed at the side.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and

determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▸ Related tests include angiography renal, calculus kidney stone panel, CT

abdomen, CT pelvis, CT renal, IVP, and MRI abdomen, retrograde ureteropyelography, US abdomen, US kidney, US pelvis, and UA.

▸ Refer to the Gastrointestinal and Genitourinary systems tables at the end of the book for related tests by body system.

Kleihauer-Betke Test

SYNONYM/ACRONYM: Fetal hemoglobin, hemoglobin F, acid elution slide test.

COMMON USE: To assist in assessing occurrence and extent of fetal maternal hemorrhage and calculate the amount of Rh immune globulin to be administered.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube. Freshly prepared blood smears are also acceptable. Cord blood may be requested for use as a positive control.

NORMAL FINDINGS: (Method: Microscopic examination of treated and stained peripheral blood smear) Less than 1% fetal cells present.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Positive findings in

- Fetal-maternal hemorrhage (*related to leakage of fetal RBCs into maternal circulation*)

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

- Hereditary persistence of fetal hemoglobin (*the test does not differentiate fetal hemoglobin from neonate and adult*)

Negative findings in: N/A

CRITICAL FINDINGS: N/A

Lactate Dehydrogenase and Isoenzymes

SYNONYM/ACRONYM: LDH and isos, LD, and isos.

COMMON USE: To assess myocardial or skeletal muscle damage toward diagnosing disorders such as myocardial infarction or damage to brain, liver, kidneys, and skeletal muscle.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Enzymatic [L to P] for lactate dehydrogenase, electrophoretic analysis for isoenzymes) Reference ranges are method dependent and may vary among laboratories.

Lactate Dehydrogenase

Age	Conventional & SI Units
0–2 yr	125–275 units/L
2–3 yr	166–232 units/L
4–6 yr	104–206 units/L
7–12 yr	90–203 units/L
13–14 yr	90–199 units/L
15–43 yr	90–156 units/L
Greater than 43 yr	90–176 units/L

LDH Fraction	% of Total	Fraction of Total
LDH ₁	14–26	0.14–0.26
LDH ₂	29–39	0.29–0.39
LDH ₃	20–26	0.2–0.26
LDH ₄	8–16	0.08–0.16
LDH ₅	6–16	0.06–0.16

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Total LDH Increased In

LDH is released from any damaged cell in which it is stored so conditions that affect the heart, liver, kidneys, red blood cells, skeletal muscle, or other tissue source and cause

cellular destruction demonstrate elevated LDH levels.

- Carcinoma of the liver
- Chronic alcoholism
- Cirrhosis
- Congestive heart failure
- Hemolytic anemias
- Hypoxia
- Leukemias
- Megaloblastic and pernicious anemia
- MI or pulmonary infarction
- Musculoskeletal disease
- Obstructive jaundice
- Pancreatitis
- Renal disease (severe)
- Shock
- Viral hepatitis

Total LDH Decreased In: N/A

LDH Isoenzymes

- LDH₁ fraction increased over LDH₂ can be seen in acute MI, anemias (pernicious, hemolytic, acute sickle cell, megaloblastic, hemolytic), and acute renal cortical injury due to any cause. The LDH₁ fraction in particular is elevated in cases of germ cell tumors.
- Increases in the middle fractions are associated with conditions in which massive platelet destruction has occurred (e.g., pulmonary embolism, post-transfusion period) and in

lymphatic system disorders (e.g., infectious mononucleosis, lymphomas, lymphocytic leukemias).

- An increase in LDH₅ occurs with musculoskeletal damage

and many types of liver damage (e.g., cirrhosis, cancer, hepatitis).

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Lactic Acid

SYNONYM/ACRONYM: Lactate.

COMMON USE: To assess for lactic acid acidosis related to poor organ perfusion and liver failure. May also be used to differentiate between lactic acid acidosis and ketoacidosis by evaluating blood glucose levels.

SPECIMEN: Plasma (1 mL) collected in a gray-top (sodium fluoride) or a green-top (lithium heparin) tube. Specimen should be transported tightly capped and in an ice slurry.

NORMAL FINDINGS: (Method: Spectrophotometry/enzymatic analysis)

	Conventional Units	SI Units (Conventional Units × 0.111)
0–90 d	3–32 mg/dL	0.3–3.6 mmol/L
3–24 mo	3–30 mg/dL	0.3–3.3 mmol/L
2 yr–adult	3–23 mg/dL	0.3–2.6 mmol/L

DESCRIPTION: Lactic acid, also known as lactate, is a by-product of anaerobic carbohydrate metabolism. Pyruvate, the normal end product of glucose metabolism, is converted to lactate in situations when energy is needed but there is insufficient oxygen in the system to favor the aerobic and customary energy cycle. Lactic acid levels increase with strenuous exercise, heart failure, severe infection, sepsis, or shock. Lactic acid levels can also increase from liver disease

or damage, because lactate is normally metabolized by the liver. Lactic acidosis can be differentiated from ketoacidosis by the absence of ketosis and grossly elevated glucose levels.

This procedure is contraindicated for: N/A

INDICATIONS

- Assess tissue oxygenation
- Evaluate acidosis

POTENTIAL DIAGNOSIS

Increased in

The liver is the major organ responsible for the breakdown of lactic acid. Any condition affecting normal liver function may also reflect increased blood levels of lactic acid.

- Cardiac failure (*decreased blood flow and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis*)
- Diabetes (*inefficient aerobic glycolysis and decreased blood flow caused by diabetes result in accumulation of lactic acid from anaerobic glycolysis*)
- Hemorrhage (*decreased blood circulation and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis*)
- Hepatic coma (*related to liver damage and decreased tissue oxygenation*)
- Ingestion of large doses of alcohol or acetaminophen (*related to liver damage*)
- Lactic acidosis (*related to strenuous exercise that results in accumulations in metabolic by-products of anaerobic breakdown of sugars for energy*)
- Pulmonary embolism (*decreased blood flow and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis*)
- Pulmonary failure (*decreased blood flow and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis*)
- Reye's syndrome (*related to liver damage*)
- Shock (*decreased blood flow and insufficient oxygen in tissues result in accumulation of lactic acid from anaerobic glycolysis*)

- Strenuous exercise (*related to lactic acidosis*)

Decreased in: N/A

CRITICAL FINDINGS

Adults

- Greater than 31 mg/dL (SI: Greater than 3.4 mmol/L)

Children

- Greater than 37 mg/dL (SI: Greater than 4.1 mmol/L)

Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Observe the patient for signs and symptoms of elevated levels of lactate, such as Kussmaul's breathing and increased pulse rate. In general, there is an inverse relationship between critically elevated lactate levels and survival.

INTERFERING FACTORS

- Drugs that may increase lactate levels include albuterol, aspirin, anticonvulsants (long-term use), isoniazid, metformin (Glucophage), oral contraceptives, sodium bicarbonate, and sorbitol.
- Falsely low lactate levels are obtained in samples with elevated levels of the enzyme lactate dehydrogenase because this enzyme reacts with the available lactate substrate.
- Using a tourniquet or instructing the patient to clench his or her fist during a venipuncture can cause elevated levels.
- Engaging in strenuous physical activity (i.e., activity in which blood flow and oxygen distribution cannot keep pace with increased energy needs) before specimen collection can cause an elevated result.
- Delay in transport of the specimen to the laboratory must be avoided. Specimens not processed by centrifugation in a tightly stoppered collection container within 15 min of collection should be rejected for analysis. It is preferable to transport specimens to the laboratory in an ice slurry to further retard cellular metabolism that might shift lactate levels in the sample before analysis.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE**Potential Nursing Problems:**

Problem	Signs & Symptoms	Interventions
Confusion (<i>Related to hepatic dysfunction; decreased tissue oxygenation</i>)	Disorganized thinking, restlessness, irritability, altered concentration and attention span, changeable mental function over the day, hallucinations	Treat the medical condition; correlate confusion with the need to reverse altered electrolytes; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or restraints; consider pharmacological interventions; record accurate intake and output to assess fluid status
Fever (<i>Related to liver disease; infection</i>)	Continuous low-grade temperature that is unaltered by treatment with antibiotics; temperature variances secondary to cirrhosis and liver damage; elevated white blood cells (WBCs); positive sepsis screen	Take temperature every 4 hr and trend for continuous low-grade fever; administer prescribed antipyretics as appropriate; administer prescribed antibiotics as appropriate; provide clean linens to keep cool and comfortable (diaphoresis); provide cooling measures (light clothing)

(table continues on page 1016)

Problem	Signs & Symptoms	Interventions
Electrolyte (<i>Related to altered metabolic process; decreased oxygenation; hepatic dysfunction; shock; sepsis; excessive alcohol intake</i>)	Altered EKG; decreased serum bicarbonate; elevated lactic acid; symptoms of shock (cool, clammy skin, decreased mental status, decreased urinary output, hypotension); diagnosis of liver failure; elevated WBC (sepsis, HIV infection); elevated blood glucose (DKA)	Correlate lactic acid imbalance with disease process (liver function, shock, DKA); collaborate with the pharmacist and health-care provider (HCP) for appropriate pharmacologic interventions; assess and trend serum lactic acid and bicarbonate levels; assess and monitor arterial blood gas bicarbonate results; monitor EKG; administer sodium bicarbonate therapy as clinically appropriate (use extreme caution because use is controversial); monitor and trend blood glucose; assess for alcoholism (causing hepatic dysfunction)
Gas exchange (<i>Related to obstruction secondary to embolism; shock</i>)	Decreased activity tolerance; increased shortness of breath with activity; weakness; orthopnea; cyanosis; cough; increased heart rate; weight gain; edema in the lower extremities; weakness; increased respiratory rate; use of respiratory accessory muscles	Auscultate and trend breath sounds; use pulse oximetry to monitor oxygenation; administer oxygen as ordered; collaborate with physician to consider intubation and/or mechanical ventilation; place the head of the bed in high Fowler's position; administer diuretics, vasodilators as ordered; monitor potassium levels

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with assessing organ function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, endocrine, hepatobiliary,

musculoskeletal, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Instruct the patient to rest for 1 hr before specimen collection. Inform the patient that specimen collection takes approximately 5 to 10 min. Address

concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ Instruct the patient to fast and to restrict fluids overnight. Instruct the patient not to ingest alcohol for 12 hr before the test. Protocols may vary among facilities.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no medication restrictions unless by medical direction.
- ▶ Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions and other pretesting preparations; ensure that food and liquids have been restricted for at least 12 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Instruct the patient *not* to clench and unclench fist immediately before or during specimen collection. Do not use a tourniquet. Perform a venipuncture. The tightly capped sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture

site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet and fluids, as directed by the HCP.
- ▶ **Nutritional Considerations:** Instruct patients to consume water when exercising. Dehydration may occur when the body loses water during exercise. Early signs of dehydration include dry mouth, thirst, and concentrated dark yellow urine. If replacement fluids are not consumed at this time, the patient may become moderately dehydrated and exhibit symptoms of extreme thirst, dry oral mucus membranes, inability to produce tears, decreased urinary output, and lightheadedness. Severe dehydration manifests as confusion, lethargy, vertigo, tachycardia, anuria, diaphoresis, and loss of consciousness.
- ▶ Note that depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that an untreated elevated lactic acid has the potential to be life threatening
- ▶ States understanding of abstaining from alcohol to protect liver function

Skill

- Follows the recommendation to refrain from excessive physical activity that may cause increased lactic acid levels
- Accurately describes symptoms of hypoxemia that should be reported to HCP

Attitude

- Expresses willingness to make lifestyle changes that will improve overall health
- Complies with the HCP therapeutic regime to manage blood glucose

RELATED MONOGRAPHS:

- Related laboratory tests include ALT, alveolar/arterial oxygen ratio, ammonia, analgesic and antipyretic drugs, anion gap, AST, biopsy liver, blood gases, CK, glucose, ketones, plethysmography, potassium, prolactin, pulse oximetry, and sodium.
- Refer to the Cardiovascular, Endocrine, Hepatobiliary, Musculoskeletal, and Respiratory systems tables at the end of the book for related tests by body system.

Lactose Tolerance Test

SYNONYM/ACRONYM: LTT.

COMMON USE: To assess for lactose intolerance or other metabolic disorders.

SPECIMEN: Plasma (1 mL) collected in a gray-top (fluoride/oxalate) tube.

NORMAL FINDINGS: (Method: Spectrophotometry)

Change in Glucose Value*	Conventional Units	SI Units (Conventional Units × 0.0555)
Normal	Greater than 30 mg/dL	Greater than 1.7 mmol/L
Inconclusive	20–30 mg/dL	1.1–1.7 mmol/L
Abnormal	Less than 20 mg/dL	Less than 1.1 mmol/L

*Compared to fasting sample for infants, children, adults, and older adults.

DESCRIPTION: Lactose is a disaccharide found in dairy products. When ingested, lactose is broken down in the intestine by the sugar-splitting enzyme lactase, into glucose and galactose. When sufficient lactase is not available, intestinal bacteria metabolize the lactose, resulting in abdominal bloating, pain, flatus, and diarrhea. The lactose tolerance test screens for lactose intolerance

by monitoring glucose levels after ingestion of a dose of lactose. There is also a noninvasive method to determine lactose intolerance using the hydrogen breath test. The breakdown of lactose by intestinal bacteria produces hydrogen gas. Before the administration of lactose, the patient breathes into a balloon. The concentration of hydrogen is measured from a sample of

the gas in the balloon. After the administration of lactose, the patient breathes into a balloon at 15-min intervals over a period of 3 to 5 hr, and subsequent samples are measured for levels of hydrogen gas. The breath test is considered normal if the increase in hydrogen is less than 12 parts per million over the fasting or pretest level.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate patients for suspected lactose intolerance

POTENTIAL DIAGNOSIS

Glucose Levels Increased In

- Normal response

Glucose Levels Decreased In

- Lactose intolerance (lactase is insufficient to break down ingested lactose into glucose)

CRITICAL FINDINGS

Glucose

Adults & Children

- Less than 40 mg/dL (SI: Less than 2.22 mmol/L)
- Greater than 400 mg/dL (SI: Greater than 22.2 mmol/L)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies

is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Symptoms of decreased glucose levels include headache, confusion, hunger, irritability, nervousness, restlessness, sweating, and weakness. Possible interventions include oral or IV administration of glucose, IV or intramuscular injection of glucagon, and continuous glucose monitoring.

Symptoms of elevated glucose levels include abdominal pain, fatigue, muscle cramps, nausea, vomiting, polyuria, and thirst. Possible interventions include subcutaneous or IV injection of insulin with continuous glucose monitoring.

INTERFERING FACTORS

- Numerous medications may alter glucose levels (see monograph titled "Glucose").
- Delayed gastric emptying may decrease glucose levels.
- Smoking may falsely increase glucose levels.
- Failure to follow dietary and activity restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to altered gastrointestinal motility secondary to lactase deficiency</i>)	Lower abdominal cramping; gas; bloating; diarrhea	Instruct patient to eliminate or reduce consumption of dairy products; instruct patient to self-administer oral enzyme medication to manage lactose when ingested
Nutrition (<i>Related to the inability to digest dairy products secondary to lactase deficiency</i>)	Intolerance to dairy products; a history of lower abdominal cramping, gas, bloating, and diarrhea with the ingestion of dairy products	Obtain a history of gastrointestinal (GI) upset with the ingestion of dairy products; trial a lactose-free diet to assess if the symptoms of GI upset will resolve; instruct in self-administration of oral enzyme medication to manage lactose when ingested; instruct patient to abstain or limit obvious sources of dairy from the diet such as milk, ice cream, cheese; assess foods for hidden dairy ingredients such as found in sherbet, sauces, gravy, and desserts.
Diarrhea (<i>Related to gastric irritation secondary to bowel irritation from undigested lactose</i>)	Frequent diarrhea after ingesting dairy products with lower abdominal cramping; gas; bloating	Instruct patient to eliminate or reduce consumption of dairy products; instruct patient to self-administer oral enzyme medication to manage lactose when ingested
Socialization (<i>Related to fear of explosive diarrhea secondary to bowel irritation from undigested lactose</i>)	Lower abdominal cramping; gas; bloating; pain; explosive diarrhea; embarrassment; fear of the inability to locate a bathroom when needed	Assist the patient to map out restroom locations in areas where they commonly socialize; encourage the patient to follow a lactose-free or limited diet; instruct the patient to self-administer oral enzyme medication to manage lactose when ingested to prevent explosive diarrhea and urgency

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist with evaluating tolerance to dairy products which contain lactose.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Obtain the pediatric patient's weight to calculate dose of lactose to be administered. Inform the patient that multiple samples will be collected over a 90-min interval. Inform the patient that each specimen collection takes approximately 5 to 10 min. Address concerns about pain related to the procedure. Inform the patient that the test may produce symptoms such as cramps and diarrhea. Instruct the patient not to smoke cigarettes or chew gum during the test. Explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Inform the patient that fasting for at least 12 hr before the test is required and that strenuous activity should also be avoided for at least 12 hr before the test. Protocols may vary among facilities.
- ▶ Note that there are no medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:**

The test may produce symptoms such as cramps and diarrhea that may

range in intensity from mild to severe.

- ▶ Ensure that the patient has complied with dietary and activity restrictions as well as other pretesting preparations; ensure that food has been restricted for at least 12 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Administer lactose dissolved in a small amount of room temperature water (250 mL), over a 5- to 10-min period. Dosage is 2 g/kg body weight to a maximum of 50 g for patients of all ages. The requesting HCP may specify a lower challenge dose if severe lactose intolerance is suspected. One pound is equal to 0.45 kg; therefore, a weight of 50 lb is equal to 22 kg. The appropriate dosage of lactose in this example would be 45 g. Record body weight, dose administered, and time of ingestion. Encourage the patient to drink one to two glasses of water during the test.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Samples should be collected at baseline, 15, 30, 60, 90, and 120 min. Record any symptoms the patient reports throughout the course of the test.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. Glucose values change rapidly in an unprocessed, unpreserved specimen; therefore, if a Microtainer

is used, each sample should be transported immediately after collection.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Instruct the patient with lactose intolerance to avoid milk products and to carefully read labels on prepared products. Yogurt, which contains inactive lactase enzyme, may be ingested. The lactase in yogurt is activated by the temperature and pH of the duodenum and substitutes for the lack of endogenous lactase. Advise the patient that products such as Lactaid tablets or drops may allow ingestion of milk products without sequelae. Many lactose-free food products are now available in grocery stores.
- ▶ Recognize anxiety related to test results, and be supportive of concerns related to a perceived change in lifestyle.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient that resuming his or her usual diet may not be possible if lactose intolerance is identified.
- ▶ Educate patients on the importance of following the dietary advice of a nutritionist to ensure proper nutritional balance.
- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.

- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient regarding lifestyle changes that will be necessary to manage lactose intolerance on a daily basis.
- ▶ Teach the patient about lactose intolerance support groups that may assist in making lifestyle adjustments.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that calcium supplements may need to be taken with the elimination or reduction of dairy products in the diet
- ▶ Composes a list of sources of dairy in the diet that may need to be eliminated

Skills

- ▶ Selects foods that exclude dietary lactose
- ▶ Demonstrates proficiency in self-administration of medication to manage lactose intolerance symptoms

Attitude

- ▶ Complies with the dietary limitation of dairy products to prevent lactose intolerance flares
- ▶ Follows normal social activities

RELATED MONOGRAPHS:

- ▶ Related tests include D-xylose absorption, fecal analysis, and glucose.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Laparoscopy, Abdominal

SYNONYM/ACRONYM: Abdominal peritoneoscopy.

COMMON USE: To visualize and assess the liver, gallbladder, and spleen to assist with surgical interventions, staging tumor, and performing diagnostic biopsies.

AREA OF APPLICATION: Abdomen and pelvis

CONTRAST: Carbon dioxide (CO₂).

DESCRIPTION: Abdominal or gastrointestinal (GI) laparoscopy provides direct visualization of the liver, gallbladder, spleen, and stomach after insufflation of carbon dioxide (CO₂). In this procedure, a rigid laparoscope is introduced into the body cavity through a 1- to 2-cm abdominal incision. The endoscope has a microscope to allow visualization of the organs, and it can be used to insert instruments for performing certain procedures, such as biopsy and tumor resection. Under general anesthesia, the peritoneal cavity is inflated with 2 to 3 L of CO₂. The gas distends the abdominal wall so that the instruments can be inserted safely. Advantages of this procedure compared to an open laparotomy include reduced pain, reduced length of stay at the hospital or surgical center, and reduced time off from work.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

-  Patients with bleeding disorders, especially those associated with uremia and cytotoxic chemotherapy.
-  Patients with cardiac conditions or dysrhythmias.
-  Patients with advanced respiratory or cardiovascular disease.
-  Patients with intestinal obstruction, abdominal mass, abdominal hernia, or suspected intra-abdominal hemorrhage.
-  Patients with a history of peritonitis or multiple abdominal operations causing dense adhesions.

INDICATIONS

- Assist in performing surgical procedures such as cholecystectomy, appendectomy, hernia repair, hiatal hernia repair, and bowel resection
- Detect cirrhosis of the liver
- Detect pancreatic disorders
- Evaluate abdominal pain or abdominal mass of unknown origin
- Evaluate abdominal trauma in an emergency
- Evaluate and treat appendicitis
- Evaluate the extent of splenomegaly due to portal hypertension
- Evaluate jaundice of unknown origin
- Obtain biopsy specimens of benign or cancerous tumors

- Stage neoplastic disorders such as lymphomas, Hodgkin's disease, and hepatic carcinoma

POTENTIAL DIAGNOSIS

Normal findings in

- Normal appearance of the liver, spleen, gallbladder, pancreas, and other abdominal contents

Abnormal findings in

- Abdominal adhesions
- Appendicitis
- Ascites
- Cancer of any of the organs
- Cirrhosis of the liver
- Gangrenous gallbladder
- Intra-abdominal bleeding
- Portal hypertension
- Splenomegaly

CRITICAL FINDINGS

- Appendicitis

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a

notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear visualization

- Gas or feces in the GI tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Patients who are in a hypoxemic or hypercapnic state will require continuous oxygen administration.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the abdominal organs.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's gastrointestinal and hepatobiliary systems, symptoms, and results of previously

performed laboratory tests and diagnostic and surgical procedures.

- ▶ Ensure that this procedure is performed before any barium studies.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a surgery department, by an HCP, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution's policy.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists

has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

- Complications of the procedure may include bleeding and cardiac arrhythmias. Patients with acute infection or advanced malignancy involving the abdominal wall are at increased risk for infection because organisms may be introduced into the normally sterile peritoneal cavity.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions for at least 8 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Ensure that nonallergy to anesthesia is confirmed before the procedure is performed under general anesthesia.
- ▶ Assess for completion of bowel preparation according to the institution's procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

- ▶ Obtain and record baseline vital signs.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer medications, as ordered, to reduce discomfort and to promote relaxation and sedation.
- ▶ Place the patient on the laparoscopy table. If general anesthesia is to be used, it is administered at this time. Place the patient in a modified lithotomy position with the head tilted downward. Cleanse the abdomen with an antiseptic solution, and drape and catheterize the patient, if ordered.
- ▶ The HCP identifies the site for the scope insertion and administers local anesthesia if that is to be used. After deeper layers are anesthetized, a pneumoperitoneum needle is placed between the visceral and parietal peritoneum.
- ▶ CO₂ is insufflated through the pneumoperitoneum needle to separate the abdominal wall from the viscera and to aid in visualization of the abdominal structures. The pneumoperitoneum needle is removed, and the trocar and laparoscope are inserted through the incision.
- ▶ After the examination, collection of tissue samples, and performance of therapeutic procedures, the scope is withdrawn. All possible CO₂ is evacuated via the trocar, which is then removed. The skin incision is closed with sutures, clips, or sterile strips, and a small dressing or adhesive strip is applied.
- ▶ Observe/assess the incision site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, and medication, as directed by the HCP.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline

values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.

- ▶ Instruct the patient to restrict activity for 2 to 7 days after the procedure.
- ▶ Instruct the patient in the care and assessment of the incision site.
- ▶ If indicated, inform the patient of a follow-up appointment for the removal of sutures.
- ▶ Inform the patient that shoulder discomfort may be experienced for 1 or 2 days after the procedure as a result of abdominal distention caused by insufflation of CO₂ into the abdomen and that mild analgesics and cold compresses, as ordered, can be used to relieve the discomfort.
- ▶ Emphasize that any persistent shoulder pain, abdominal pain, vaginal bleeding, fever, redness, or swelling of the incisional area must be reported to the HCP immediately.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include amylase, barium swallow, biopsy bone marrow, CBC, CBC WBC count and differential, CT abdomen, CT biliary tract and liver, CT pancreas, CRP, ESR, gallium scan, hepatobiliary scan, KUB, lipase, liver and spleen scan, lymphangiogram, MRI abdomen, MRI pelvis, peritoneal fluid analysis, US abdomen, and US pelvis.
- ▶ Refer to the Gastrointestinal and Hepatobiliary systems tables at the end of the book for related tests by body system.

Laparoscopy, Gynecologic

SYNONYM/ACRONYM: Gynecologic pelviscopy, gynecologic laparoscopy, pelvic endoscopy, peritoneoscopy.

COMMON USE: To visualize and assess the ovaries, fallopian tubes, and uterus toward diagnosing inflammation, malformations, cysts, and fibroids and to evaluate causes of infertility.

AREA OF APPLICATION: Pelvis.

CONTRAST: Carbon dioxide (CO₂).

DESCRIPTION: Gynecologic laparoscopy provides direct visualization of the internal pelvic contents, including the ovaries, fallopian tubes, and uterus, after insufflation of carbon dioxide (CO₂). It is done to diagnose and treat pelvic organ disorders as well as to perform surgical procedures on the organs. In this procedure, a rigid laparoscope is introduced into the body cavity through a 1- to 2-cm periumbilical incision. The endoscope has a microscope to allow visualization of the organs, and it can be used to insert instruments for performing procedures such as biopsy (e.g., biopsy of suspected endometrial lesions) and tumor resection. Under general or local anesthesia, the peritoneal cavity is inflated with 2 to 3 L of CO₂. The gas distends the abdominal wall so that the instruments can be inserted safely. Advantages of this procedure compared to an open laparotomy include reduced pain, reduced length of stay at the hospital or surgical center, and reduced time off from work.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients with bleeding disorders, especially those associated with uremia and cytotoxic chemotherapy.
-  Patients with cardiac conditions or dysrhythmias.
-  Patients with advanced respiratory or cardiovascular disease.
-  Patients with intestinal obstruction, abdominal mass, abdominal hernia, or suspected intra-abdominal hemorrhage.

INDICATIONS

- Detect ectopic pregnancy and determine the need for surgery
- Detect pelvic inflammatory disease or abscess
- Detect uterine fibroids, ovarian cysts, and uterine malformations (ovarian cysts may be aspirated during the procedure)
- Evaluate amenorrhea and infertility
- Evaluate fallopian tubes and anatomic defects to determine the cause of infertility
- Evaluate known or suspected endometriosis, salpingitis, and hydrosalpinx

- Evaluate pelvic pain or masses of unknown cause
- Evaluate reproductive organs after therapy for infertility
- Obtain biopsy specimens to confirm suspected pelvic malignancies or metastasis
- Perform tubal sterilization and ovarian biopsy
- Perform vaginal hysterectomy
- Remove adhesions or foreign bodies such as intrauterine devices
- Treat endometriosis through electrocautery or laser vaporization

POTENTIAL DIAGNOSIS

Normal findings in

- Normal appearance of uterus, ovaries, fallopian tubes, and other pelvic contents

Abnormal findings in

- Ectopic pregnancy
- Endometriosis
- Ovarian cyst
- Ovarian tumor
- Pelvic adhesions
- Pelvic inflammatory disease
- Pelvic tumor
- Salpingitis
- Uterine fibroids

CRITICAL FINDINGS

- Ectopic pregnancy
- Foreign body
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP,

Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear visualization

- Gas or feces in the gastrointestinal (GI) tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.
- Patients who are in a hypoxemic or hypercapnic state will require continuous oxygen administration.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the abdominal and pelvic organs.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that this procedure is performed before any barium studies.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a surgery department by an HCP and support staff and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Inform the patient that a laxative and cleansing enema may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution's policy.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted

for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.

- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Complications of the procedure may include bleeding and cardiac arrhythmias. Patients with acute infection or advanced malignancy involving the abdominal wall are at increased risk for infection because organisms may be introduced into the normally sterile peritoneal cavity.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions for at least 8 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Ensure that nonallergy to anesthesia is confirmed before the procedure is performed under general anesthesia.
- ▶ Assess for completion of bowel preparation according to the institution's procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

- ▶ Obtain and record baseline vital signs.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer medications, as ordered, to reduce discomfort and to promote relaxation and sedation.
- ▶ Place the patient on the laparoscopy table. If general anesthesia is to be used, it is administered at this time. Place the patient in a modified lithotomy position with the head tilted downward. Cleanse the abdomen with an antiseptic solution, and drape and catheterize the patient, if ordered.
- ▶ The HCP identifies the site for the scope insertion and administers local anesthesia if that is to be used. After deeper layers are anesthetized, a pneumoperitoneum needle is placed between the visceral and parietal peritoneum.
- ▶ CO₂ is insufflated through the pneumoperitoneum needle to separate the abdominal wall from the viscera and to aid in visualization of the abdominal structures. The pneumoperitoneum needle is removed, and the trocar and laparoscope are inserted through the incision.
- ▶ The HCP inserts a uterine manipulator through the vagina and cervix and into the uterus so that the uterus, fallopian tubes, and ovaries can be moved to permit better visualization.
- ▶ After the examination, collection of tissue samples, and performance of therapeutic procedures (e.g., tubal ligation), the scope is withdrawn. All possible CO₂ is evacuated via the trocar, which is then removed. The skin incision is closed with sutures, clips, or sterile strips and a small dressing or adhesive strip is applied. After the perineum is cleansed, the uterine manipulator is removed and a sterile pad applied.
- ▶ Observe/assess the incision site for bleeding, inflammation, or hematoma formation.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Instruct the patient to restrict activity for 2 to 7 days after the procedure.
- ▶ Instruct the patient in the care and assessment of the incision site.
- ▶ If indicated, inform the patient of a follow-up appointment for the removal of sutures.
- ▶ Inform the patient that shoulder discomfort may be experienced for 1 or 2 days after the procedure as a result of abdominal distention caused by insufflation of CO₂ into the abdomen and that mild analgesics and cold compresses, as ordered, can be used to relieve the discomfort.
- ▶ Emphasize that any persistent shoulder pain, abdominal pain, vaginal bleeding, fever, redness, or swelling of the incisional area must be reported to the HCP immediately.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, and medication, as directed by the HCP.

RELATED MONOGRAPHS:

- ▶ Related tests include cancer antigens, *Chlamydia* group antibody, CT abdomen, CT pelvis, HCG, MRI pelvis, Pap smear, progesterone, US pelvis, and uterine fibroid embolization.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Latex Allergy

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess for allergic reaction to products containing latex.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunoassay) Negative.

This procedure is contraindicated for: N/A *Negative findings in:* N/A

POTENTIAL DIAGNOSIS

Positive findings in
Latex allergy

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

CRITICAL FINDINGS: N/A

Lead

SYNONYM/ACRONYM: Pb.

COMMON USE: To assess for lead toxicity and monitor exposure to lead to assist in diagnosing lead poisoning.

SPECIMEN: Whole blood (1 mL) collected in a special lead-free royal blue- or tan-top tube. Plasma (1 mL) collected in a lavender-top (EDTA) tube is also acceptable.

NORMAL FINDINGS: (Method: Atomic absorption spectrophotometry)

	Conventional Units	SI Units (Conventional Units × 0.0483)
Children and adults (WHO, CDC; environmental exposure)	Less than 10 mcg/dL	Less than 0.48 micromol/L
OSHA (occupational exposure standard)	Less than 40 mcg/dL	Less than 1.93 micromol/L

OSHA = Occupational Safety and Health Administration; WHO = World Health Organization; CDC = Centers for Disease Control and Prevention.

DESCRIPTION: Lead is a heavy metal and trace element found in the environment. It is absorbed through the respiratory and gastrointestinal systems. It can also be transported from mother to fetus through the placenta. When there is frequent exposure to lead-containing items (e.g., paint, batteries, gasoline, pottery, bullets, printing materials) or occupations (mining, automobile, printing, and welding industries), lead poisoning can cause severe behavioral and neurological effects. The blood test is considered the best indicator of lead poisoning.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis and treatment of lead poisoning

POTENTIAL DIAGNOSIS

Increased in

Heme synthesis involves the conversion of D-amino levulinic acid to porphobilinogen. Lead interferes with the enzyme that is responsible for this critical step in heme synthesis, amino levulinic acid dehydrase.

- Anemia of lead intoxication
- Lead encephalopathy
- Metal poisoning

Decreased in: N/A

CRITICAL FINDINGS

- Levels greater than 30 mcg/dL (SI: Greater than 1.4 micromol/L) indicate significant exposure
- Levels greater than 60 mcg/dL (SI: Greater than 2.9 micromol/L) may require chelation therapy

Note and immediately report to the health-care provider (HCP) any

critically increased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Contamination of the collection site and/or specimen with lead in dust can be avoided by taking special care to have the surfaces surrounding the collection location cleaned. Extra care should also be used to avoid contamination during the actual venipuncture.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in detecting lead exposure.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a history of the patient's exposure to lead.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label

the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

- ▶ Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include δ -aminolevulinic acid, CBC, CBC RBC morphology, erythrocyte protoporphyrin, and urine porphyrins.
- ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Leukocyte Alkaline Phosphatase

SYNONYM/ACRONYM: LAP, LAP score, LAP smear.

COMMON USE: To monitor response to therapy in Hodgkin's disease and diagnose other disorders of the hematological system such as aplastic anemia.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Microscopic evaluation of specially stained blood smears) 25 to 130 (score based on 0 to 4+ rating of 100 neutrophils).

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Conditions that result in an increase in leukocytes in all stages of maturity will reflect a corresponding increase in LAP.

- Aplastic leukemia
- Chronic inflammation
- Down's syndrome
- Hairy cell leukemia
- Hodgkin's disease
- Leukemia (acute and chronic lymphoblastic)
- Myelofibrosis with myeloid metaplasia
- Multiple myeloma
- Polycythemia vera (*increase in all blood cell lines, including leukocytes*)

- Pregnancy
- Stress
- Thrombocytopenia

Decreased in

- Chronic myelogenous leukemia
- Hereditary hypophosphatemia (*insufficient phosphorus levels*)
- Idiopathic thrombocytopenia purpura
- Nephrotic syndrome (*excessive loss of phosphorus*)
- Paroxysmal nocturnal hemoglobinuria (*possibly related to the absence of LAP and other proteins anchored to the red blood cell wall, resulting in complement-mediated hemolysis*)
- Sickle cell anemia
- Sideroblastic anemia

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Lipase

SYNONYM/ACRONYM: Triacylglycerol acylhydrolase.

COMMON USE: To assess for pancreatic disease related to inflammation, tumor, or cyst, specific to the diagnosis of pancreatitis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Enzymatic spectrophotometry)

Conventional & SI Units

Newborn–older adult
0–60 units/L

DESCRIPTION: Lipases are digestive enzymes secreted by the pancreas into the duodenum. There are different lipolytic enzymes with specific substrates, but they are collectively described as lipase. Lipase participates in fat digestion by breaking down triglycerides into fatty acids and glycerol so the fatty acids can be absorbed and either used for energy or stored for later use. Lipase is released into the bloodstream when damage occurs to the pancreatic acinar cells. Its presence in the blood indicates pancreatic disease because the pancreas is the only organ that secretes this enzyme.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of acute and chronic pancreatitis
- Assist in the diagnosis of pancreatic carcinoma

POTENTIAL DIAGNOSIS

Increased in

Lipase is contained in pancreatic tissue and is released into the serum when cell damage or necrosis occurs.

- Acute cholecystitis
- Obstruction of the pancreatic duct
- Pancreatic carcinoma (early)
- Pancreatic cyst or pseudocyst
- Pancreatic inflammation
- Pancreatitis (acute and chronic)
- Renal failure (*related to decreased renal excretion*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase lipase levels include acetaminophen, asparaginase, azathioprine, calcitriol, cholinergics, codeine, deoxycholate, diazoxide, didanosine, felbamate, glycocholate, hydrocortisone, indomethacin, meperidine, methacholine, methylprednisolone, metolazone, morphine, narcotics, nitrofurantoin, pancreozymin, pegaspargase, pentazocine, and taurocholate.
- Drugs that may decrease lipase levels include protamine and saline (IV infusions).

- Endoscopic retrograde cholangiopancreatography may increase lipase levels.
- Serum lipase levels increase with hemodialysis. Therefore, predialysis specimens should be collected for lipase analysis.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Nutrition (<i>Related to altered pancreatic function; excess alcohol intake; insufficient eating habits; altered pancreatic and liver function</i>)	Known inadequate caloric intake; weight loss; muscle wasting in arms and legs; stool that is pale or gray colored; skin that is flaky with loss of elasticity	Document food intake with possible calorie count; assess barriers to eating; consider using a food diary; monitor continued alcohol use as it is a barrier to adequate protein nutrition; monitor glucose levels; record daily weight; provide dietary consult with assessment of cultural food selections
Fluid volume (<i>Related to vomiting; decreased oral intake; diaphoresis; nothing by mouth [NPO] with a nasogastric tube [NGT]; overly aggressive fluid resuscitation; compromised renal function; overly aggressive diuresis</i>)	Deficient: decreased urinary output, fatigue, and sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status. Overload: edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values	Record daily weight and monitor trends; record accurate intake and output; collaborate with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes as ordered

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to organ inflammation and surrounding tissues; excessive alcohol intake; infection</i>)	Emotional symptoms of distress; crying; agitation; facial grimace; moaning; verbalization of pain; rocking motions; irritability; disturbed sleep; diaphoresis; altered blood pressure and heart rate; nausea; vomiting; self-report of pain; upper abdominal and gastric pain after eating fatty foods or alcohol intake with acute pancreatic disease; pain may be decreased or absent in chronic pancreatic disease	Collaborate with the patient and physician to identify the best pain management modality to provide relief; refrain from activities that may aggravate pain; use the application of heat or cold to the best effect in managing the pain; monitor pain severity
Breathing (<i>Related to abdominal distention; ascites; pleural effusion; respiratory failure</i>)	Dyspnea; shortness of breath; increased work of breathing; nasal flare; respiratory rate greater than 24 breaths per minute; tachypnea; use of accessory muscles for breathing; anxiety	Monitor for cyanosis and pallor; monitor effect of administered medication on respiratory effort; evaluate need for intubation or mechanical ventilation; monitor and trend vital signs and rate and effort; monitor for snoring when sleeping; auscultate and assess for adventitious breath sounds

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing pancreatitis.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Instruct the patient to ingest small, frequent meals if he or she has a gastrointestinal disorder; advise the patient to consider other dietary alterations as well. After acute symptoms subside and bowel sounds return, patients are usually prescribed a clear liquid diet, progressing to a low-fat, high-carbohydrate diet.
- ▶ Administer vitamin B₁₂, as ordered, to the patient with decreased lipase levels, especially if his or her disease prevents adequate absorption of the vitamin.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Encourage the alcoholic patient to avoid alcohol and to seek appropriate counseling for substance abuse.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Recognize anxiety related to test results and answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient and the patient's family that they should report any difficulty of breathing or shortness of breath to the nurse for immediate intervention.
- ▶ Reinforce information provided by the physician that intubation or mechanical ventilation may be necessary to support breathing if there is no improvement.

Expected Patient Outcomes:**Knowledge**

- ▶ Designs a plan of care for home that will support improved breathing
- ▶ Identifies signs and symptoms that would indicate compromised breathing

Skills

- ▶ Proficiently demonstrates relaxation techniques that will improve their breathing pattern
- ▶ Follows the prescribed therapeutic interventions that will improve lung ventilation

Attitude

- ▶ Complies with prescribed pain management to improve breathing
- ▶ Accepts information about advance directive options

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, ALP, amylase, AST, bilirubin, calcitonin stimulation, calcium, cancer antigens, cholangiography percutaneous transhepatic, cholesterol, CBC, CBC WCB count and diff, ERCP, fecal fat, GGT, hepatobiliary scan, magnesium, MRI pancreas, mumps serology, pleural fluid analysis, peritoneal fluid analysis, triglycerides, US abdomen, and US pancreas.
- ▶ Refer to the Gastrointestinal and Hepatobiliary systems tables at the end of the book for related tests by body system.

Lipoprotein Electrophoresis

SYNONYM/ACRONYM: Lipid fractionation; lipoprotein phenotyping; $3\alpha_1$ -lipoprotein cholesterol, high-density lipoprotein (HDL); β -lipoprotein cholesterol, low-density lipoprotein (LDL); pre- β -lipoprotein cholesterol, very-low-density lipoprotein (VLDL).

COMMON USE: To assist in categorizing lipoprotein as an indicator of cardiac health.

SPECIMEN: Serum (3 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Electrophoresis and 4°C test for specimen appearance) There is no quantitative interpretation of this test. The specimen appearance and electrophoretic pattern is visually interpreted.

Hyperlipoproteinemia: Fredrickson Type	Specimen Appearance	Electrophoretic Pattern
Type I	Clear with creamy top layer	Heavy chylomicron band
Type IIa	Clear	Heavy β band
Type IIb	Clear or faintly turbid	Heavy β and pre- β bands
Type III	Slightly to moderately turbid	Heavy β band
Type IV	Slightly to moderately turbid	Heavy pre- β band
Type V	Slightly to moderately turbid with creamy top layer	Intense chylomicron band and heavy β and pre- β bands

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

- **Type I:** Hyperlipoproteinemia, or increased chylomicrons, can be primary **resulting from an inherited deficiency of lipoprotein lipase** or secondary **caused by uncontrolled diabetes, systemic lupus erythematosus, and dysgamma-globulinemia**. Total cholesterol is normal to moderately elevated, and triglycerides (mostly exogenous

chylomicrons) are grossly elevated. If the condition is inherited, symptoms will appear in childhood.

- **Type IIa:** Hyperlipoproteinemia can be primary **resulting from inherited characteristics** or secondary **caused by uncontrolled hypothyroidism, nephrotic syndrome, and dysgamma-globulinemia**. Total cholesterol is elevated, triglycerides are normal, and LDLC is elevated. If the condition is inherited, symptoms will appear in childhood.

- **Type IIb:** Hyperlipoproteinemia *can occur for the same reasons as in type IIa*. Total cholesterol, triglycerides, and LDLC are all elevated.
- **Type III:** Hyperlipoproteinemia can be primary **resulting from inherited characteristics** or secondary **caused by hypothyroidism, uncontrolled diabetes, alcoholism, and dysgammaglobulinemia**. Total cholesterol and triglycerides are elevated, whereas LDLC is normal.
- **Type IV:** Hyperlipoproteinemia can be primary **resulting from inherited characteristics** or secondary **caused by poorly controlled diabetes, alcoholism, nephrotic syndrome, chronic renal failure, and dysgammaglobulinemia**. Total cholesterol is normal to moderately elevated, triglycerides are moderately to grossly elevated, and LDLC is normal.
- **Type V:** Hyperlipoproteinemia can be primary **resulting from inherited characteristics**, or secondary **caused by uncontrolled diabetes, alcoholism, nephrotic syndrome, and dysgammaglobulinemia**. Total cholesterol is normal to moderately elevated, triglycerides are grossly elevated, and LDLC is normal.

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Liver and Spleen Scan

SYNONYM/ACRONYM: Liver and spleen scintigraphy, radionuclide liver scan, spleen scan.

COMMON USE: To visualize and assess the liver and spleen related to tumors, inflammation, cysts, abscess, trauma, and portal hypertension.

AREA OF APPLICATION: Abdomen.

CONTRAST: IV radioactive technetium-99m sulfur colloid.

DESCRIPTION: The liver and spleen scan is performed to help diagnose abnormalities in the function and structure of the liver and spleen. It is often performed in combination with lung scanning to help diagnose masses or inflammation in the diaphragmatic area. This procedure is useful for evaluating right-upper-quadrant pain, metastatic disease, jaundice,

cirrhosis, ascites, traumatic infarction, and radiation-induced organ cellular necrosis. Technetium-99m (Tc-99m) sulfur colloid is injected IV and rapidly taken up through phagocytosis by the reticuloendothelial cells, which normally function to remove particulate matter, including radioactive colloids in the liver and spleen. False-negative results may occur in

patients with space-occupying lesions (e.g., tumors, cysts, abscesses) smaller than 2 cm. This scan can detect portal hypertension, demonstrated by a greater uptake of the radionuclide in the spleen than in the liver. Single-photon emission computed tomography (SPECT) has significantly improved the resolution and accuracy of liver scanning. SPECT enables images to be recorded from multiple angles around the body and reconstructed by a computer to produce images or “slices” representing the organ at different levels. For evaluation of a suspected hemangioma, the patient’s red blood cells are combined with Tc-99m and images are recorded over the liver. To confirm the diagnosis, liver and spleen scans are done in conjunction with computed tomography (CT), magnetic resonance imaging (MRI), ultrasonography (US), and SPECT scans and interpreted in light of the results of liver function tests.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Assess the condition of the liver and spleen after abdominal trauma
- Detect a bacterial or amebic abscess
- Detect and differentiate between primary and metastatic tumor focal disease
- Detect benign tumors, such as adenoma and cavernous hemangioma

- Detect cystic focal disease
- Detect diffuse hepatocellular disease, such as hepatitis and cirrhosis
- Detect infiltrative processes that affect the liver, such as sarcoidosis and amyloidosis
- Determine superior vena cava obstruction or Budd-Chiari syndrome
- Differentiate between splenomegaly and hepatomegaly
- Evaluate the effects of lower abdominal trauma, such as internal hemorrhage
- Evaluate jaundice
- Evaluate liver and spleen damage caused by radiation therapy or toxic drug therapy
- Evaluate palpable abdominal masses

POTENTIAL DIAGNOSIS

Normal findings in

- Normal size, contour, position, and function of the liver and spleen

Abnormal findings in

- Abscesses
- Cirrhosis
- Cysts
- Hemangiomas
- Hematomas
- Hepatitis
- Hodgkin’s disease
- Infarction
- Infection
- Infiltrative process (amyloidosis and sarcoidosis)
- Inflammation of the diaphragmatic area
- Metastatic tumors
- Nodular hyperplasia
- Portal hypertension
- Primary benign or malignant tumors
- Traumatic lesions

CRITICAL FINDINGS

- Visceral injury

It is essential that a critical finding be communicated immediately to the

requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Other nuclear scans done within the preceding 24 to 48 hr.

Other considerations

- The scan may fail to detect focal lesions smaller than 2 cm in diameter.
- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety

concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating liver and spleen function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's hematopoietic, hepatobiliary, and immune systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to

the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injection of radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**, hematoma **related to blood leakage into the tissue following needle insertion**, infection **that might occur if bacteria from the skin surface is introduced at the puncture site**, or nerve injury **that might occur if the needle strikes a nerve.**

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Administer sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization.
- ▶ IV radionuclide is administered, and the abdomen is scanned immediately to screen for vascular lesions with images taken in various positions.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ The patient may be imaged by SPECT techniques to further clarify areas of suspicious radionuclide localization.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting HCP, who will discuss the results with the patient.

- ▶ Instruct the patient to resume usual medication and activity, as directed by the HCP.
- ▶ Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ **Nutritional Considerations:** A low-fat, low-cholesterol, and low-sodium diet

should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.

- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALT, antibodies antimitochondrial, AST, bilirubin, biopsy liver, CT abdomen, CT biliary tract and liver, GGT, HAV, HBV, HCV, hepatobiliary scan, MRI abdomen, and US liver.
- ▶ Refer to the Hematopoietic, Hepatobiliary, and Immune systems tables at the end of the book for related tests by body system.

Lung Perfusion Scan

SYNONYM/ACRONYM: Lung perfusion scintigraphy, lung scintiscan, pulmonary scan, radioactive perfusion scan, radionuclide lung scan, ventilation-perfusion scan, V/Q scan.

COMMON USE: To assess pulmonary blood flow to assist in diagnosis of pulmonary embolism.

AREA OF APPLICATION: Chest/thorax.

CONTRAST: IV radioactive material, usually macroaggregated albumin (MAA).

DESCRIPTION: The lung perfusion scan is a nuclear medicine study performed to evaluate a patient for pulmonary embolus (PE) or other pulmonary disorders. Technetium (Tc-99m) is injected IV and distributed throughout the pulmonary vasculature because of the gravitational effect on perfusion. The scan, which produces a visual image of pulmonary blood flow, is useful in diagnosing or confirming pulmonary vascular obstruction. The diameter of the IV-injected macroaggregated albumin (MAA) is larger than that of the pulmonary capillaries; therefore, the MAA temporarily becomes lodged in the pulmonary vasculature. A gamma camera detects the radiation emitted from the injected radioactive material, and a representative image of the lung is obtained. This procedure is often done in conjunction with the lung ventilation scan to obtain clinical information that assists in differentiating among the many possible pathological conditions revealed by the procedure. The results are correlated with other diagnostic studies, such as pulmonary function, chest x-ray, pulmonary angiography, and arterial blood gases. A recent chest x-ray is essential for accurate interpretation of the lung perfusion scan. An area of nonperfusion seen in the same area as a pulmonary parenchymal abnormality on the chest x-ray indicates that a PE is not present; the defect may represent some other pathological condition, such as pneumonia.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients with atrial and ventricular septal defects *because the MAA particles will not reach the lungs.*
-  Patients with pulmonary hypertension.

INDICATIONS

- Aid in the diagnosis of PE in a patient with a normal chest x-ray
- Detect malignant tumor
- Differentiate between PE and other pulmonary diseases, such as pneumonia, pulmonary effusion, atelectasis, asthma, bronchitis, emphysema, and tumors
- Evaluate perfusion changes associated with congestive heart failure and pulmonary hypertension
- Evaluate pulmonary function preoperatively in a patient with pulmonary disease

POTENTIAL DIAGNOSIS

Normal findings in

- Diffuse and homogeneous uptake of the radioactive material by the lungs

Abnormal findings in

- Asthma
- Atelectasis
- Bronchitis
- Chronic obstructive pulmonary disease
- Emphysema
- Left atrial or pulmonary hypertension

- Lung displacement by fluid or chest masses
- Pneumonia
- Pneumonitis
- PE
- Tuberculosis

CRITICAL FINDINGS

- PE

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Other nuclear scans done on the same day.

Other considerations

- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Compare with baseline values. Protocols may vary among facilities.
- ▶ Instruct the patient to resume usual medication and activity, as directed by the HCP.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and

- discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include α -1 AT, eosinophil count, ACE, alveolar/arterial gradient, angiography pulmonary, biopsy lung, blood gases, blood pool imaging, bronchoscopy, carbon dioxide, chest x-ray, CBC, CBC WCB count and differential, CT thoracic, culture and smear mycobacteria, culture blood, culture throat, culture sputum, culture viral, cytology sputum, ESR, IgE, gallium scan, lung ventilation scan, MRI chest, MRI venography, mediastinoscopy, plethysmography, pleural fluid analysis, PET heart, PFT, pulse oximetry, and TB skin tests.
- ▶ Refer to the Respiratory System table at the end of the book for related tests by body system.

Lung Ventilation Scan

SYNONYM/ACRONYM: Aerosol lung scan, radioactive ventilation scan, ventilation scan, VQ lung scan, xenon lung scan.

COMMON USE: To assess pulmonary ventilation to assist in diagnosis of pulmonary embolism.

AREA OF APPLICATION: Chest/thorax.

CONTRAST: Done with inhaled radioactive material (xenon gas or technetium-DTPA).

DESCRIPTION: The lung ventilation scan is a nuclear medicine study performed to evaluate a patient for pulmonary embolus (PE) or other pulmonary disorders. It can evaluate respiratory function (i.e., demonstrating areas of the lung that are patent and capable of ventilation) and dysfunction (e.g., parenchymal abnormalities affecting ventilation, such as pneumonia). The procedure is performed after the patient inhales air mixed with a radioactive gas through a face mask and mouthpiece. The radioactive gas delineates areas of the lung during ventilation. The distribution of the gas throughout the lung is measured in three phases:

- *Wash-in phase:* Phase during buildup of the radioactive gas
- *Equilibrium phase:* Phase after the patient rebreathes from a closed delivery system
- *Wash-out phase:* Phase after the radioactive gas has been removed

This procedure is usually performed along with a lung perfusion scan. When PE is present, ventilation scans display a normal wash-in

and wash-out of radioactivity from the lung areas. Parenchymal disease responsible for perfusion abnormalities will produce abnormal wash-in and wash-out phases. This test can be used to quantify regional ventilation in patients with pulmonary disease.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of PE
- Differentiate between PE and other pulmonary diseases, such as pneumonia, pulmonary effusion, atelectasis, asthma, bronchitis, emphysema, and tumors
- Evaluate regional respiratory function
- Identify areas of the lung that are capable of ventilation
- Locate hypoventilation (regional), which can result from chronic obstructive pulmonary disease (COPD) or excessive smoking

POTENTIAL DIAGNOSIS

Normal findings in

- Equal distribution of radioactive gas throughout both lungs and a normal wash-out phase

Abnormal findings in

- Atelectasis
- Bronchitis
- Bronchogenic carcinoma
- COPD
- Emphysema
- PE
- Pneumonia
- Regional hypoventilation
- Sarcoidosis
- Tuberculosis
- Tumor

CRITICAL FINDINGS

- PE

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Other nuclear scans done within the preceding 24 to 48 hr.

Other considerations

- The presence of conditions that affect perfusion or ventilation (e.g., tumors that obstruct the pulmonary artery, vasculitis, pulmonary edema, sickle cell disease, parasitic disease, emphysema, effusion, infection) can simulate a perfusion defect similar to PE.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing

gloves. Then wash hands after the gloves are removed.

- ▶ **Nutritional Considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes and/or decrease risk of hypertension and coronary artery disease.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include α -1 antitrypsin, alveolar/arterial ratio, ACE, angiography pulmonary, biopsy lung, blood gases, blood pool imaging, bronchoscopy, carbon dioxide, chest x-ray, CBC, CBC WBC count and differential, CT thorax, culture and smear mycobacteria, culture blood, culture sputum, culture throat, culture viral, cytology sputum, D-dimer, gallium scan, lung perfusion scan, MRI chest, MRI venography, mediastinoscopy, plethysmography, pleural fluid analysis, PET heart, PFT, TB skin tests, US venous Doppler extremity studies, and venography.
- ▶ Refer to the Respiratory System table at the end of the book for related tests by body system.

Lupus Anticoagulant Antibodies

SYNONYM/ACRONYM: Lupus inhibitor phospholipid type, lupus antiphospholipid antibodies, LA.

COMMON USE: To assess for systemic dysfunction related to anticoagulation and assist in diagnosing conditions such as lupus erythematosus and fetal loss.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Dilute Russell viper venom test time) Negative.

DESCRIPTION: Lupus anticoagulant (LA) antibodies are immunoglobulins, usually of the immunoglobulin G class. They are also called lupus antiphospholipid antibodies because they interfere with phospholipid-dependent coagulation tests such as activated partial thromboplastin time (aPTT) by reacting with the phospholipids in the test system. They are not associated with a bleeding disorder unless thrombocytopenia or antiprothrombin antibodies are already present. They are associated with an increased risk of thrombosis. The combination of noninflammatory thrombosis of blood vessels, low platelet count, and history of miscarriage is termed *antiphospholipid antibody syndrome* and is confirmed by the presence of at least one of the clinical criteria (vascular thrombosis confirmed by histopathology or imaging studies; pregnancy morbidity defined as either one or more unexplained deaths of a morphologically normal fetus at or beyond the 10th week of gestation, one or more premature births of a morphologically normal neonate before the 34th

week of gestation due to eclampsia or severe pre-eclampsia, or three or more unexplained consecutive spontaneous abortions before the 10th week of gestation) and one of the laboratory criteria (ACA, IgG, or IgM, detectable at greater than 40 units on two or more occasions at least 12 weeks apart; or LA detectable on two or more occasions at least 12 weeks apart; or anti- β_2 glycoprotein 1 antibody, IgG, or IgM, detectable on two or more occasions at least 12 weeks apart, all measured by a standardized ELISA, according to recommended procedures).

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate prolonged aPTT
- Investigate reasons for fetal death

POTENTIAL DIAGNOSIS

Positive findings in

- Antiphospholipid antibody syndrome (*LA are nonspecific antibodies associated with this syndrome*)

- Fetal loss (*thrombosis associated with LA can form clots that lodge in the placenta and disrupt nutrition to the fetus*)
- Raynaud's disease (*LA can be detected with this condition and can cause vascular inflammation*)
- Rheumatoid arthritis (*LA can be detected with this condition and can cause vascular inflammation*)
- Systemic lupus erythematosus (*related to formation of thrombi as a result of LA binding to phospholipids on cell walls*)
- Thromboembolism (*related to formation of thrombi as a result of LA binding to phospholipids on cell walls*)

Negative findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may cause a positive LA test result include calcium channel blockers, heparin, hydralazine, hydantoin, isoniazid, methyldopa, phenytoin, phenothiazine,

procainamide, quinine, quinidine, and Thorazine.

- Placement of a tourniquet for longer than 1 min can result in venous stasis and changes in the concentration of plasma proteins to be measured. Platelet activation may also occur under these conditions, causing erroneous results.
- Vascular injury during phlebotomy can activate platelets and coagulation factors, causing erroneous results.
- Hemolyzed specimens must be rejected because hemolysis is an indication of platelet and coagulation factor activation.
- Icteric or lipemic specimens interfere with optical testing methods, producing erroneous results.
- Hematocrit greater than 55% may cause falsely prolonged results because of anticoagulant excess relative to plasma volume.
- Incompletely filled collection tubes, specimens contaminated with heparin, clotted specimens, or unprocessed specimens not delivered to the laboratory within 1 to 2 hr of collection should be rejected.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to joint inflammation and stiffness</i>)	Report of joint pain; emotional symptoms of distress; crying; agitation; facial grimace; moaning; rocking motions; irritability; disturbed sleep; diaphoresis; altered blood pressure and heart rate; nausea; vomiting	Collaborate with the patient and physician to identify the best pain management modality to provide relief; refrain from activities that may aggravate pain; use the application of heat or cold to the best effect in managing the pain; monitor pain severity; administer prescribed opioids; discuss with patient what has worked to relieve joint pain in the past; assess the effect of pain on personal, social, and professional obligations;

Problem	Signs & Symptoms	Interventions
Fatigue <i>(Related to associated anemia; disease progression; depression; pain; disturbed rest)</i>	Decreased concentration; increased physical complaints; inability to restore energy with sleep; reports being tired; inability to maintain normal routine; depression; excessive sleep; diminished performance	take prescribed anti-inflammatory medication; consider using a bed cradle to keep weight of linens off of legs; collaborate with physical therapy to splint joints; discuss use of imagery or distraction to control pain; avoid prolonged periods of inactivity that could exacerbate joint pain and stiffness Assess for physical cause of fatigue; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia; provide adequate rest periods; encourage warm shower or bath before bedtime; instruct patient to change position frequently while sleeping
Grief <i>(Related to loss of relationship with potential child [fetal loss])</i>	Anger; blame; emotional distress; despair; helplessness; powerlessness; emotional pain; depression; detachment; crying; loud vocalization of grief; shock	Assess for behaviors that indicate grief; assess for shock, disbelief; identify stage of grieving; assess for cultural or spiritual aspects of grief; assess decision-making capacity that may be altered due to grief; collaborate with social services to support patient during time of grief; listen and allow the patient to verbalize feelings; encourage self-care activities to support own health and healing; refer to community resources such as grief support groups; consider recommendation of pharmacological intervention as appropriate

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that this test can assist in evaluation of clotting disorders.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic, immune, musculoskeletal, and reproductive systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Heparin therapy should be discontinued 2 days before specimen collection, with medical direction. Coumarin therapy should be discontinued 2 wk before specimen collection, with medical direction.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Ensure that the patient has complied with pretesting preparations; assure that anticoagulant therapy has been restricted as required prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the

patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Fill tube completely. *Important note:* When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) tubes. Otherwise, when using a standard vacutainer system, the blue-top tube is the first tube collected. When a butterfly is used, due to the added tubing, an extra red-top tube should be collected before the blue-top tube to ensure complete filling of the blue-top tube.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. The CLSI recommendation for processed and unprocessed samples stored in unopened tubes is that testing should be completed within 1 to 4 hr of collection.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and offer support.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to resume usual medications, as directed by the HCP.

- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Take time to discuss feelings the mother and father may experience (e.g., guilt, depression, anger) if test results are abnormal.
- ▶ Teach patient to avoid caffeinated foods before bedtime.
- ▶ Educate the patient regarding access to counseling services. Provide contact information, if desired, for the Lupus Foundation of America (www.lupus.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that taking anti-inflammatory medication as early as possible in the morning will decrease joint stiffness sooner
- ▶ States understanding that anti-inflammatory medication should not be taken on an empty stomach

Skills

- ▶ Demonstrates effective use of alternative measures (imagery, distraction) to manage pain
- ▶ Demonstrates proficiency for range-of-motion exercises that can be used to decrease joint stiffness

Attitude

- ▶ Complies with recommendation to attend grief counseling to assist in managing grief process
- ▶ Complies with recommendation to attend grief support group, sharing grief experiences can assist emotional healing

RELATED MONOGRAPHS:

- ▶ Related tests include antibody, anticardiolipin antibodies, anticyclic citrullinated peptide, ANA, arthroscopy, BMD, bone scan, CRP, ESR, FDP, MRI musculoskeletal, aPTT, protein S, PT/INR and mixing studies, radiography bone, RF, synovial fluid analysis, and US obstetric.
- ▶ Refer to the Hematopoietic, Immune, Musculoskeletal, and Reproductive systems tables at the end of the book for related tests by body system.

Luteinizing Hormone

SYNONYM/ACRONYM: LH, luteotropin, interstitial cell-stimulating hormone (ICSH).

COMMON USE: To assess gonadal function related to fertility issues and response to therapy.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Immunoassay)

Concentration by Gender and by Phase (in Females)**Conventional and SI Units**

Male

Less than 2 yr

0.5–1.9 international units/mL

2–10 yr

Less than 0.5 international units/mL

11–20 yr

0.5–5.3 international units/mL

Adult

1.2–7.8 international units/mL

Female

Less than 2–10 yr

Less than 0.5 international units/mL

11–20 yr

0.5–9 international units/mL

Phase in Females

Follicular

1.7–15 international units/mL

Ovulatory

21.9–80 international units/mL

Luteal

0.6–16.3 international units/mL

Postmenopausal

14.2–52.3 international units/mL

DESCRIPTION: The secretion and inhibition of human reproductive hormones is maintained by a fine balance of feedback mechanisms involving the hypothalamus, pituitary gland, ovaries, and testes. Gonadotropin-releasing hormone (Gn-RH), a peptide neurohormone produced and released by the hypothalamus, signals the anterior pituitary gland to release luteinizing hormone and follicle-stimulating hormone. GnRH is secreted during the neonatal period and gonadotropins are detectable in the blood at an early age. A negative feedback mechanism initiated by FSH and LH levels inhibits further secretion by suppressing the release of Gn-RH until puberty. During the prepubital period and following into adulthood, nocturnal pulses of Gn-RH induce nocturnal, pulsatile secretions of luteinizing hormone (LH). The mechanism by which increased release of Gn-RH permits increased secretion of gonadotropins is not well understood. LH affects gonadal function in both men and women. In women, a surge of LH normally occurs at

the midpoint of the menstrual cycle (ovulatory phase) due to initiation of a positive feedback loop involving estrogen and which results in ovulation. As the corpus luteum develops progesterone levels rise, signaling the pituitary to stop secreting LH. In males, LH stimulates the interstitial cells of Leydig, located in the testes, to produce testosterone. For this reason, in reference to males, LH is sometimes called interstitial cell-stimulating hormone. Serial specimens may be required to accurately demonstrate blood levels.

This procedure is contraindicated for: N/A

INDICATIONS

- Distinguish between primary and secondary causes of gonadal failure
- Evaluate children with precocious puberty
- Evaluate male and female infertility, as indicated by decreased LH levels
- Evaluate response to therapy to induce ovulation
- Support diagnosis of infertility caused by anovulation, as

evidenced by lack of LH surge at the midpoint of the menstrual cycle

POTENTIAL DIAGNOSIS

Increased in

Conditions of decreased gonadal function cause a feedback response that stimulates LH secretion.

- Anorchia
- Gonadal failure
- Menopause
- Primary gonadal dysfunction

Decreased in

- Anorexia nervosa (*pathophysiology is unclear*)
- Kallmann's syndrome (*pathophysiology is unclear*)
- Malnutrition (*pathophysiology is unclear*)
- Pituitary or hypothalamic dysfunction (*these organs control production of LH; failure of the pituitary to produce LH or of the hypothalamus to produce gonadotropin-releasing hormone results in decreased LH levels*)
- Severe stress (*pathophysiology is unclear*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and hormones that may increase LH levels include clomiphene, gonadotropin-releasing hormone, goserelin, ketoconazole, leuprolide, mestranol, nafarelin, naloxone, nilutamide, spironolactone, and tamoxifen.
- Drugs and hormones that may decrease LH levels include anabolic steroids, anticonvulsants, conjugated estrogens, cyproterone, danazol, digoxin, D-Trp-6-LHRH, estradiol valerate, estrogen/progestin therapy, finasteride, ganirelix, goserelin, ketoconazole, leuprolide, desogestrel/ethinylestradiol (Marvelon), medroxyprogesterone, megestrol, metformin, methandrostenolone, norethindrone, octreotide, oral contraceptives, phenothiazine, pimozide, pravastatin, progesterone, stanozolol, and tamoxifen.
- In menstruating women, values vary in relation to the phase of the menstrual cycle.
- LH secretion follows a circadian rhythm, with higher levels occurring during sleep.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Self-esteem (<i>Related to altered self-view associated with infertility</i>)	Verbalizes feelings that express being a failure as a man or woman associated with inability to impregnate or become pregnant; dissatisfaction with present state of intimacy with significant other	Monitor for negative self-statements; assess for withdrawal; monitor for real or perceived rejection of others; encourage verbalization of self-worth; encourage discussion of perceived changes in family role; monitor for anxiety; recommend personal and family counseling; facilitate support group participation

(table continues on page 1060)

Problem	Signs & Symptoms	Interventions
Knowledge <i>(Related to recent diagnosis; complexity of treatment; poor understanding of provided information; cultural or language barriers; anxiety; emotional disturbance; unfamiliar with medical management)</i>	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management; verbalizes inaccurate information; lack of follow-through with directions	Identify patient's, family's, and significant other's concerns about disease process; provide information regarding fertility testing and treatment; encourage participation in a support group to decrease anxiety
Anxiety <i>(Related to failure versus desire to conceive)</i>	Stated feelings of inadequacy, helplessness; restlessness and irritability; altered sleep pattern; lack of appetite or overeating; difficulty concentrating and focusing	Assess the level of anxiety; assist the patient to identify coping strategies that will decrease anxiety; administer prescribed medications to decrease anxiety; provide education that is culturally and age appropriate, and at an appropriate literacy level; encourage a discussion of fears and concerns causing the anxiety; refer to social services and a support group as applicable
Powerlessness <i>(Related inability to become pregnant secondary to failure to ovulate)</i>	Expression of loss of control over situation, self, outcome of disease; passive; apathetic; submissive; decreased participation in self-care; reluctant to express feelings	Assess need to be in control; assess feelings of hopelessness, depression, apathy; assess the impact of the sense of powerlessness on the patient's sense of self; encourage verbalization of feelings; discuss therapeutic options offered by health-care provider (HCP); assist to identify strengths; identify coping strategies

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing hormone and fertility disorders.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and reproductive systems, symptoms, and results of previously

performed laboratory tests and diagnostic and surgical procedures.

- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. If the test is being performed to detect ovulation, inform the patient that it may be necessary to obtain a series of samples over a period of several days to detect peak LH levels. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting health-care provider (HCP), who will discuss the results with the patient.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Instruct the patient in the use of home ovulation test kits approved by the U.S. Food and Drug Administration, as appropriate.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding of the purpose of repeating laboratory studies to monitor and trend hormone levels
- ▶ States understanding of alternative methods to achieve pregnancy as described by HCP

Skills

- ▶ Accurately describes the purpose of future laboratory studies to monitor hormone levels and evaluate response to therapy
- ▶ Accurately self-administers medication to decrease anxiety

Attitude

- ▶ Agrees to attend a support group for those who have infertility concerns
- ▶ Identifies nonpharmacological coping strategies that will help to decrease anxiety

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, antisperm antibody, estradiol, FSH, progesterone, prolactin, and testosterone.
- ▶ Refer to the Endocrine and Reproductive systems tables at the end of the book for related tests by body system.

Lyme Antibody

SYNONYM/ACRONYM: N/A.

COMMON USE: To detect antibodies to the organism that causes Lyme disease.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Enzyme immunoassay) Less than 0.91 index; positives are confirmed by Western blot analysis.

DESCRIPTION: *Borrelia burgdorferi*, a deer tick-borne spirochete, is the organism that causes Lyme disease. Lyme disease affects multiple systems and is characterized by fever, arthralgia, and arthritis. The circular, red rash characterizing erythema migrans can appear 3 to 30 days after the tick bite. About one-half of patients in the early stage of Lyme disease (stage 1) and generally all of those in the advanced stage (stage 2—with cardiac, neurological, and rheumatoid manifestations) will have a positive test result. Patients in remission will also have a positive test response. The presence of immunoglobulin M (IgM) antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. The Centers for Disease Control and Prevention (CDC) recommends a two-step testing process that begins with an immunofluorescence or enzyme-linked immunosorbent assay.

(ELISA) and is confirmed by using a Western blot test.

This procedure is contraindicated for: N/A

INDICATIONS

Assist in establishing a diagnosis of Lyme disease

POTENTIAL DIAGNOSIS

Positive findings in Lyme disease

Negative findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- High rheumatoid-factor titers as well as cross-reactivity with Epstein-Barr virus and other spirochetes (e.g., *Rickettsia*, *Treponema*) may cause false-positive results.
- Positive test results should be confirmed by the Western blot method.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to Borrelia burgdorferi bacteria; transmission of B. burgdorferi bacteria in utero from infected mother to baby</i>)	Macular flush; flu-like symptoms; headache; extreme fatigue; neck pain; joint pain; joint swelling; bone pain; classic bull's-eye rash; unexplained fever; difficulty swallowing; chest pain; shortness of breath; heart palpitations; nausea; vomiting; pain in feet; twitching; numbness; irritability; visual disturbance; mood swings; depression; paranoia	Administer prescribed antibiotics; administer prescribed medications to treat symptoms; minimize future exposure by following these recommendations: stay out of the woods in spring and summer, stay toward the center of the hiking trail, do not sit on the ground in leafy/grassy wooded areas, complete frequent self-check for ticks, wear long-sleeved shirts, tuck pants into your socks, tuck shirt into your pants, wear light-colored clothing to make attached ticks more visible, use bug repellent with DEET, strip down and do a full body check after being outdoors in endemic areas, check your pets for ticks
Fatigue (<i>Related to B. burgdorferi bacteria infection</i>)	Decreased concentration; increased physical complaints; unable to restore energy with sleep; reports being tired; unable to maintain normal routine	Assess for physical cause of fatigue; pace activities to preserve energy stores; rate fatigue on a numeric scale to trend degree of fatigue over time; identify what aggravates and decreases fatigue; assess for related emotional factors such as depression; evaluate current medications in relation to fatigue; assess for physiologic factors such as anemia
Anxiety (<i>Related to physical and mental changes that may or may not be reversible secondary to</i>	Consequences of <i>B. burgdorferi</i> infection to lifestyle and individual functionality; insomnia;	Assess coping strategies used and their effectiveness; acknowledge the presence of anxiety; keep a calm presence while interacting with the

(table continues on page 1064)

Problem	Signs & Symptoms	Interventions
bacterial infection with <i>B. burgdorferi</i> associated with tick bite)	restlessness; irritability; difficulty concentrating; anorexia; focus on self; expressions of concern; apprehension	patient; administer prescribed medications to decrease anxiety; use simple, straightforward language to increase understanding and decrease anxiety; support selected coping strategies; facilitate referral for psychiatric evaluation as needed; refer to Lyme disease support group

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing Lyme disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex. Discuss history of exposure; ask the patient if he or she lives in or visits wooded areas, wears long pants and long-sleeved shirts when in wooded areas or when doing yard work, or has ever been bitten by a tick.
- ▶ Obtain a history of the patient's immune and musculoskeletal systems, symptoms, a history of exposure, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to perceived loss of independence and fear of shortened life expectancy. Lyme disease can be debilitating and can result in significant changes in lifestyle. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and

information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Warn the patient that false-positive test results can occur and that false-negative test results frequently occur. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Advise the patient to wear light-colored clothing that covers extremities when in areas infested by deer ticks and to check body for ticks after returning from infested areas.
- ▶ Emphasize the importance of reporting continued signs and symptoms of the infection.

- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that tick bite risk increases in specific designated geographical areas
- ▶ States understanding of the importance of taking prescribed antibiotic to treat infection, including that repeated antibiotic treatments may be necessary

Skills

- ▶ Describes clothing that would be appropriate to use in prevention of tick bites
- ▶ Demonstrates proficiency in the self-administering of the prescribed antibiotic

Attitude

- ▶ Follows recommendation to take measures to prevent future tick bites
- ▶ Complies with recommendation to attend support group to decreased anxiety and increase understanding of disease process

RELATED MONOGRAPHS:

- ▶ Related tests include ANA, CBC, ESR, rheumatoid factor, and synovial fluid analysis.
- ▶ Refer to the Immune and Musculoskeletal systems tables at the end of the book for related tests by body system.

Lymphangiography

SYNONYM/ACRONYM: Lymphangiogram.

COMMON USE: To visualize and assess the lymphatic system related to diagnosis of lymphomas such as Hodgkin's disease.

AREA OF APPLICATION: Lymphatic system.

CONTRAST: IV iodine-based contrast medium.

DESCRIPTION: Lymphangiography involves visualization of the lymphatic system after the injection of an iodinated oil-based contrast medium into a lymphatic vessel in the hand or foot. The lymphatic system collects and filters lymph fluid; moving the fluid in one direction from the surrounding tissues to the neck where it re-enters the circulatory system. The lymphatic system consists of lymph vessels, lymph ducts, lymph nodes, tonsils, adenoids, spleen, and thymus. Lymph is a colorless to white fluid composed of lymphocytes (white blood cells [WBCs] produced by the bone marrow and thymus), excess plasma proteins, and chyle (emulsified fats) from the intestines. The filtration units of the lymphatic system are the lymph nodes and organs located in different parts of the body, such as the neck, armpit, groin, chest, and abdomen. The main function of the lymphatic system is to provide immunological defense for the body against injury from disease or toxic chemicals. Assessment of this system is important because cancer (e.g. lymphoma and Hodgkin's disease) often spreads via the lymphatic system. Painful edema of the extremities usually occurs when the flow of lymphatic fluid becomes obstructed by infection, injury, or cancer. Lymphangiography is performed for cancer staging in patients with an established diagnosis of lymphoma or metastatic tumor to assist in monitoring progression of the disease, to plan surgical intervention, and to monitor the effectiveness of therapeutic modalities such as chemotherapy or radiation treatment. Injection into the hand

allows visualization of the axillary and supraclavicular nodes. Injection into the foot allows visualization of the lymphatics of the leg, inguinal and iliac regions, and retroperitoneum up to the thoracic duct. Less commonly, injection into the foot can be used to visualize the cervical region (retroauricular area).

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium). Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of non-ionic contrast or an alternative non-contrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) **because iodinated contrast is nephrotoxic**
- ◆ Elderly and compromised patients who are chronically dehydrated before the test **because of their risk of contrast-induced renal failure.**
- ◆ Patients with bleeding disorders or receiving anticoagulant therapy **because the puncture site may not stop bleeding.**
- ◆ Patients with severe chronic lung disease, cardiac disease, or advanced liver disease.

INDICATIONS

- Determine the extent of adenopathy
- Determine lymphatic cancer staging
- Distinguish primary from secondary lymphedema
- Evaluate edema of an extremity without known cause
- Evaluate effects of chemotherapy or radiation therapy
- Plan surgical treatment or evaluate effectiveness of chemotherapy or radiation therapy in controlling malignant tumors

POTENTIAL DIAGNOSIS

Normal findings in

- Normal lymphatic vessels and nodes that fill completely with contrast medium on the initial films. On 24-hr images, the lymph nodes are fully opacified and well circumscribed. The lymphatic channels are emptied a few hours after injection of the contrast medium

Abnormal findings in

- Abnormal lymphatic vessels
- Hodgkin's disease
- Metastatic tumor involving the lymph glands

- Nodal lymphoma
- Retroperitoneal lymphomas associated with Hodgkin's disease

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Inability to cannulate the lymphatic vessels.

Other considerations

- Be aware of risks associated with the contrast medium. The oil-based contrast medium may embolize into the lungs and will temporarily diminish pulmonary function. This can produce lipid pneumonia, which is a life-threatening complication.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation

Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.
- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the lymphatic system.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's endocrine and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium. Ensure that barium studies were performed more than 4 days before lymphangiography.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note that if iodinated contrast medium is scheduled to be used in

patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**

- ▶ Review the procedure with the patient. Address concerns about pain and explain there may be moments of discomfort and some pain experienced during the test. Inform the patient that the procedure is performed by an HCP, with support staff, and takes approximately 1 to 2 hr. Inform the patient that he or she will have to return the next day, and the set of images taken upon return will take only 30 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct patient to withhold anticoagulant medication or to reduce dosage before the procedure, as ordered by the HCP.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Injection of contrast medium is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**, bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners,**

hematoma **related to blood leakage into the tissue following needle insertion**, infection **that might occur if bacteria from the skin surface is introduced at the puncture site**, dyspnea, pain, or hypotension **caused by micropulmonary emboli**, and lipid pneumonia **caused by contrast flowing into the thoracic duct**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with medication restrictions and pretesting preparations.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily accessible.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Obtain and record baseline vital signs, and assess neurological status.
- ▶ Administer a mild sedative, as ordered.
- ▶ Place the patient in a supine position on an x-ray table. Cleanse the selected area and cover with a sterile drape.
- ▶ A local anesthetic is injected at the site, and a small incision is made or a needle inserted. A blue dye is injected intradermally into the area between the toes or fingers. The lymphatic vessels are identified as the dye moves. A local anesthetic is then injected into the dorsum of each foot or hand, and a small incision is made and cannulated for injection of the contrast medium.
- ▶ The contrast medium is then injected, and the flow of the contrast medium is

followed by fluoroscopy or images. When the contrast medium reaches the upper lumbar level, the infusion of contrast medium is discontinued. X-ray images are taken of the chest, abdomen, and pelvis to determine the extent of filling of the lymphatic vessels. To examine the lymphatic nodes and to monitor the progress of delayed flow, 24-hr delayed images are taken.

- ▶ Monitor the patient for complications related to the contrast medium (e.g., allergic reaction, anaphylaxis, bronchospasm, lipid pneumonia).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ When the cannula is removed the incision is sutured and bandaged.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Monitor vital signs and neurological status every 15 min for 30 min. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe/assess the cannula insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Observe for a delayed allergic reaction to contrast medium or pulmonary embolus, which may include shortness of breath, increased heart rate, pleuritic pain, hypotension, low-grade fever, and cyanosis.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.

- ▶ Instruct the patient to maintain bedrest up to 24 hr to reduce extremity swelling after the procedure, or as ordered.
- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, biopsy lymph nodes, CBC, CBC WBC count and differential, CT abdomen, CT pelvis, CT thoracic, gallium scan, laparoscopy abdominal, liver and spleen scan, MRI abdomen, mediastinoscopy, and US lymph nodes.
- ▶ Refer to the Endocrine and Immune systems tables at the end of the book for tests by related body system.

Magnesium, Blood

SYNONYM/ACRONYM: Mg²⁺.

COMMON USE: To assess electrolyte balance related to magnesium levels to assist in diagnosis, monitoring diseases, and therapeutic interventions such as hemodialysis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units × 0.4114)
Newborn	1.7–2.5 mg/dL	0.7–1 mmol/L
Child	1.7–2.3 mg/dL	0.7–0.95 mmol/L
Adult	1.6–2.6 mg/dL	0.66–1.07 mmol/L

DESCRIPTION: Magnesium is required as a cofactor in numerous crucial enzymatic processes, such as protein synthesis, nucleic acid synthesis, and muscle contraction. Magnesium is also required for the use of adenosine diphosphate as a source of energy. It is the fourth most abundant cation and the second most abundant intracellular ion. Magnesium is needed for the transmission of nerve impulses and muscle relaxation. It controls absorption of sodium, potassium, calcium, and phosphorus; utilization of carbohydrate, lipid, and protein; and activation of enzyme systems that enable the B vitamins to function. Magnesium is also essential for oxidative phosphorylation, nucleic acid synthesis, and blood clotting. Urine magnesium levels reflect magnesium deficiency before serum levels. Magnesium deficiency severe enough to cause hypocalcemia and cardiac arrhythmias can exist despite normal serum magnesium levels.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine electrolyte balance in renal failure and chronic alcoholism
- Evaluate cardiac arrhythmias (decreased magnesium levels can lead to excessive ventricular irritability)
- Evaluate known or suspected disorders associated with altered magnesium levels
- Monitor the effects of various drugs on magnesium levels

POTENTIAL DIAGNOSIS

Increased in

- Addison's disease (*related to insufficient production of aldosterone; decreased renal excretion*)
- Adrenocortical insufficiency (*related to decreased renal excretion*)
- Dehydration (*related to hemoconcentration*)
- Diabetic acidosis (severe) (*related to acid-base imbalance*)
- Hypothyroidism (*pathophysiology is unclear*)
- Massive hemolysis (*related to release of intracellular magnesium; intracellular concentration is three times higher than normal plasma levels*)

- Overuse of antacids (*related to excessive intake of magnesium-containing antacids*)
- Renal insufficiency (*related to decreased urinary excretion*)
- Tissue trauma

Decreased in

- Alcoholism (*related to increased renal excretion and possible insufficient dietary intake*)
- Diabetic acidosis (*insulin treatment lowers blood glucose and appears to increase intracellular transport of magnesium*)
- Glomerulonephritis (chronic) (*related to diminished renal function; magnesium is reabsorbed in the renal tubules*)
- Hemodialysis (*related to loss of magnesium due to dialysis treatment*)
- Hyperaldosteronism (*related to increased excretion*)
- Hypocalcemia (*decreased magnesium is associated with decreased calcium and vitamin D levels*)
- Hypoparathyroidism (*related to decreased calcium*)
- Inadequate intake
- Inappropriate secretion of antidiuretic hormone (*related to fluid overload*)
- Long-term hyperalimentation
- Malabsorption (*related to impaired absorption of calcium and vitamin D*)
- Pancreatitis (*secondary to alcoholism*)
- Pregnancy
- Severe loss of body fluids (*diarrhea, lactation, sweating, laxative abuse*)

CRITICAL FINDINGS

Adults

- Less than 1.2 mg/dL (SI: Less than 0.5 mmol/L)
- Greater than 4.9 mg/dL (SI: Greater than 2 mmol/L)

Children

- Less than 1.2 mg/dL (SI: Less than 0.5 mmol/L)
- Greater than 4.3 mg/dL (SI: Greater than 1.8 mmol/L)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

Symptoms such as tetany, weakness, dizziness, tremors, hyperactivity, nausea, vomiting, and convulsions occur at decreased (less than 1.2 mg/dL) concentrations. Electrocardiographic (ECG) changes (prolonged P-R and Q-T intervals; broad, flat T waves; and ventricular tachycardia) may also occur. Treatment may include IV or oral administration of magnesium salts, monitoring for respiratory depression and areflexia (IV administration of magnesium salts), and monitoring for diarrhea and metabolic alkalosis (oral administration to replace magnesium).

Respiratory paralysis, decreased reflexes, and cardiac arrest occur at grossly elevated (greater than 15 mg/dL) levels. ECG changes, such as prolonged P-R and Q-T intervals, and bradycardia may be seen. Toxic levels of magnesium may be reversed with the administration of calcium, dialysis treatments, and removal of the source of excessive intake.

INTERFERING FACTORS

- Drugs that may increase magnesium levels include acetylsalicylic acid and progesterone.
- Drugs that may decrease magnesium levels include albuterol, aminoglycosides, amphotericin B, bendroflumethiazide, chlorthalidone, cisplatin, citrates, cyclosporine, digoxin, gentamicin, glucagon, and oral contraceptives.
- Magnesium is present in higher intracellular concentrations; therefore, hemolysis will result in a false

elevation in values and such specimens should be rejected for analysis.

- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution

combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fluid volume <i>(Related to metabolic imbalances associated with disease process)</i>	Deficiency: decreased urinary output, fatigue, and sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status. Overload: Edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values	Record daily weight and monitor trends; record accurate intake and output; collaborate with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes as ordered; monitor serum magnesium levels
Nutrition <i>(Related to excess caloric intake with large amounts of dietary sodium and fat; cultural lifestyle; overeating associated with anxiety,</i>	Observable obesity; high fat or sodium food selections; high BMI; high consumption of ethnic foods; sedentary lifestyle; dietary religious beliefs and food selections; binge eating; diet high in refined sugar; repetitive dieting and failure	Discuss ideal body weight and the purpose and relationship between ideal weight and caloric intake to support cardiac health; review ways to decrease intake of saturated fats and increase intake of polyunsaturated fats; discuss limiting cholesterol intake to less than 300 mg per day; discuss limiting the intake of refined processed sugar; teach limiting sodium intake to

(table continues on page 1074)

Problem	Signs & Symptoms	Interventions
<p><i>depression, compulsive disorder; genetics; inadequate or unhealthy food resources)</i></p>		<p>the health-care provider's recommended restriction; encourage intake of fresh fruits and vegetables, unprocessed carbohydrates, poultry, and grains</p>
<p>Electrolyte imbalance <i>(Related to metabolic imbalance)</i></p>	<p>Excess: Nausea; vomiting; diarrhea; diaphoresis; flushing; sensation of heat; decreased mental functioning; weakness; drowsiness; hypotension; bradycardia; respiratory depression; coma. Deficit: nystagmus; fatigue; convulsions; weakness; numbness</p>	<p>Correlate magnesium imbalance with disease process, nutritional intake, renal function, medications; monitor ECG status; monitor for respiratory changes; monitor for GI changes; minimize metabolic complications; provide a safe environment to prevent injury; collaborate with the pharmacist and health-care provider for appropriate pharmacologic interventions; adjust medication dosage to compensate for renal impairment; collaborate with dietician for dietary modifications</p>
<p>Cardiac output <i>(Related to increased preload; increased afterload; impaired cardiac contractility; cardiac muscle disease; altered cardiac conduction)</i></p>	<p>Decreased peripheral pulses; decreased urinary output; cool clammy skin; tachypnea; dyspnea; edema; altered level of consciousness; abnormal heart sounds; crackles in lungs; decreased activity tolerance; weight gain; fatigue; hypoxia</p>	<p>Assess peripheral pulses and capillary refill; monitor blood pressure and check for orthostatic changes; assess respiratory rate, breath sounds, and orthopnea; assess skin color and temperature; assess level of consciousness; monitor urinary output; use pulse oximetry to monitor oxygenation; monitor sodium and potassium levels; monitor BNP levels; administer ordered angiotensin-converting enzyme (ACE) inhibitors, beta-blockers, diuretics, aldosterone antagonists, and vasodilators; provide oxygen administration</p>

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in the evaluation of electrolyte balance.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, endocrine, gastrointestinal, genitourinary, and reproductive systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site

for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Educate the magnesium-deficient patient regarding good dietary sources of magnesium, such as green vegetables, seeds, legumes, shrimp, and some bran cereals. Advise the patient that high intake of substances such as phosphorus, calcium, fat, and protein interferes with the absorption of magnesium.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to report any signs or symptoms of electrolyte imbalance, such as dehydration, diarrhea, vomiting, or prolonged anorexia.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Recognize anxiety related to test results and answer any questions or address any concerns voiced by the patient or family.
- ▶ Educate the patient regarding access to nutritional counseling services.
- ▶ Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
- ▶ Teach the importance of maintaining an appropriate magnesium level to their overall health.
- ▶ Teach the patient that renal disease can contribute to an elevated magnesium level.

Expected Patient Outcomes:**Knowledge**

- States understanding that dietary magnesium intake may need to be decreased to prevent hypomagnesaemia
- States understanding that renal disease can contribute to high serum magnesium levels

Skills

- Accurately selects a diet that is appropriate to support their personal magnesium needs
- Identifies foods in their diet that should be added or deleted to support an appropriate magnesium level

Attitude

- Complies with the recommendation to take dietary supplements to improved magnesium levels

- Discusses the possibility of hemodialysis as needed to manage serum magnesium levels

RELATED MONOGRAPHS:

- Related tests include ACTH, aldosterone, anion gap, antiarrhythmic drugs, AST, BUN, calcium, calculus kidney stone panel, CBC WBC count and differential, cortisol, CRP, CK and isoenzymes, creatinine, glucose, homocysteine, LDH and isoenzymes, magnesium urine, myoglobin, osmolality, PTH, phosphorus, potassium, renin, sodium, troponin, US abdomen, and vitamin D.
- Refer to the Cardiovascular, Endocrine, Gastrointestinal, Genitourinary, and Reproductive systems tables at the end of the book for related tests by body system.

Magnesium, Urine

SYNONYM/ACRONYM: Urine Mg²⁺.**COMMON USE:** To assess magnesium levels related to renal function.**SPECIMEN:** Urine (5 mL) from a random or timed specimen collected in a clean plastic collection container with 6N hydrochloride as a preservative.**NORMAL FINDINGS:** (Method: Spectrophotometry)

Conventional Units	SI Units (Conventional Units × 0.4114)
20–200 mg/24 hr	8.2–82.3 mmol/24 hr

This procedure is contraindicated for: N/A**POTENTIAL DIAGNOSIS****Increased in**

- Alcoholism (*related to impaired absorption and increased urinary excretion*)

- Barter's syndrome (*inherited defect in renal tubules that results in urinary wasting of potassium and magnesium*)
- Transplant recipients on cyclosporine and prednisone (*related to increased excretion by the kidney*)

- Use of corticosteroids (*related to increased excretion by the kidney*)
- Use of diuretics (*related to increased urinary excretion*)

Decreased in

- Abnormal renal function (*related to diminished ability of renal tubules to reabsorb magnesium*)

- Crohn's disease (*related to inadequate intestinal absorption*)
- Inappropriate secretion of antidiuretic hormone (*related to diminished renal absorption*)
- Salt-losing conditions (*related to diminished renal absorption*)

CRITICAL FINDINGS: N/A

Magnetic Resonance Angiography

SYNONYM/ACRONYM: MRA.

COMMON USE: To visualize and assess blood flow in diseased and normal vessels toward diagnosis of vascular disease and to monitor and evaluate therapeutic interventions.

AREA OF APPLICATION: Vascular.

CONTRAST: Can be done with or without IV contrast (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio waves to produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the hydrogen atoms absorb the radio waves and change their

position. This change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of the vessels in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or tunnel; open MRI equipment has no sides and provides an alternative for people who suffer from claustrophobia, pediatric patients, or patients who are

obese. IV gadolinium-based contrast media may be used to better visualize the vessels and tissues in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

Magnetic resonance angiography (MRA) is an application of MRI that provides images of blood flow and diseased and normal blood vessels. In patients who are allergic to iodinated contrast medium, MRA is used in place of angiography. MRA is particularly useful for visualizing vascular abnormalities, dissections, and other pathology. Special imaging sequences allow the visualization of moving blood within the vascular system, and two common techniques are used to obtain images of flowing blood: time-of-flight and phase-contrast MRA. In time-of-flight imaging, incoming blood makes the vessels appear bright and surrounding tissue is suppressed. Phase-contrast images are produced by subtracting the stationary tissue surrounding the vessels where the blood is moving through vessels during the imaging, producing high-contrast images. MRA is the most accurate technique for imaging blood flowing in veins and small arteries (laminar flow), but it does not accurately depict blood flow in tortuous sections of vessels and distal to bifurcations and stenosis. Swirling blood may cause a signal loss and result in inadequate images, and the degree of vessel stenosis may be overestimated.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant,

unless the potential benefits of MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***

-  Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.
-  Patients with cardiac pacemakers that can be deactivated by MRI
-  Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet, ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet that can inactivate, move, or

shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys can become dangerous projectiles.

-  Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause burns to the skin *related to energy conducted through the metal which is converted to heat during the MRI*. Other metallic objects on the skin may also cause burns.
-  Patients who are claustrophobic.

INDICATIONS

- Detect pericardial abnormalities
- Detect peripheral artery disease (PAD)
- Detect thoracic and abdominal vascular diseases
- Determine renal artery stenosis
- Differentiate aortic aneurysms from tumors near the aorta
- Evaluate cardiac chambers and pulmonary vessels
- Evaluate postoperative angioplasty sites and bypass grafts
- Identify congenital vascular diseases
- Monitor and evaluate the effectiveness of medical or surgical treatment

POTENTIAL DIAGNOSIS

Normal findings in

- Normal blood flow in the area being examined, including blood flow rate

Abnormal findings in

- Aortic aneurysm
- Coarctations
- Dissections
- PAD
- Thrombosis within a vessel
- Tumor invasion of a vessel
- Vascular abnormalities
- Vessel occlusion
- Vessel stenosis

CRITICAL FINDINGS

- Aortic aneurysm
- Aortic dissection
- Occlusion
- Tumor with significant mass effect
- Vertebral artery dissection

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study.

Other considerations

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the vascular system.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- ▶ Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department by an HCP who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- ▶ Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphores (flickering lights in the visual field); these will stop when the procedure is over.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove external metallic objects from the area to be examined prior to the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Injection of the contrast is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; cardiac arrhythmias; hematoma **related to blood leakage into the tissue following needle insertion**; bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; vascular or nerve injury **that might occur if the needle strikes a nerve or nearby blood vessel**; or infection **that might occur if bacteria from the skin surface is introduced at the puncture site**.

Some patients are at risk for developing nephrogenic systemic fibrosis (NSF) as a result of the use of gadolinium-based contrast agents **related to ineffective renal clearance in patients with impaired renal function**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Supply earplugs to the patient to block out the loud, banging sounds that

occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.

- ▶ Apply MRI-safe electrodes to the appropriate sites if an electrocardiogram or respiratory gating is to be performed in conjunction with the scan.
- ▶ Establish IV fluid line for the injection IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Assist the patient onto the examination table and into the appropriate position for imaging to begin.
- ▶ Imaging can begin shortly after the injection, if contrast is used.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.

- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
 - ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the American Heart Association (www.americanheart.org), the NHLBI (www.nhlbi.nih.gov), or Legs for Life (www.legsforlife.org).
 - ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography of the body area of interest, BUN, CT angiography, creatinine, US arterial Doppler carotid, and US venous Doppler.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Magnetic Resonance Imaging, Abdomen

SYNONYM/ACRONYM: Abdominal MRI.

COMMON USE: To visualize and assess abdominal and hepatic structures toward diagnosis of tumors, metastasis, aneurysm, and abscess. Also used to monitor medical and surgical therapeutic interventions.

AREA OF APPLICATION: Liver and abdominal area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio waves to produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen

atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the hydrogen atoms absorb the radio waves and change their position; this change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of the abdomen in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be

obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or tunnel; open MRI equipment has no sides and provides an alternative for people who suffer from claustrophobia, pediatric patients, or patients who are obese. IV gadolinium-based contrast media may be used to better visualize the vessels and tissues in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

Abdominal MRI is performed to assist in diagnosing abnormalities of abdominal and hepatic structures. Contrast-enhanced imaging is effective for distinguishing peritoneal metastases from primary tumors of the gastrointestinal (GI) tract. Primary tumors of the stomach, pancreas, colon, and appendix often spread by intraperitoneal tumor shedding and subsequent peritoneal carcinomatosis. MRI uses the noniodinated paramagnetic contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance differences between normal and abnormal tissues.

Magnetic resonance cholangiopancreatography (MRCP) is an imaging technique used specifically to evaluate the hepatobiliary system that is comprised of the liver, gallbladder, bile ducts, pancreas, and pancreatic ducts. MRCP is a less invasive way than Endoscopic retrograde cholangiopancreatography (ERCP) to investigate abdominal pain, suspected malignancy, gall stones, or pancreatitis.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant,

unless the potential benefits of the MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***

-  Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.
-  Patients with cardiac pacemakers that can be deactivated by MRI.
-  Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet, ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet

that can inactivate, move, or shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys can become dangerous projectiles.

-  Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause burns to the skin *related to energy conducted through the metal which is converted to heat during the MRI*. Other metallic objects on the skin may also cause burns.
-  Patients who are claustrophobic.

INDICATIONS

- Detect abdominal aortic diseases
- Detect and stage cancer (primary or metastatic tumors of liver, pancreas, prostate, uterus, and bladder)
- Detect chronic pancreatitis
- Detect renal vein thrombosis
- Detect soft tissue abnormalities
- Determine and monitor tissue damage in renal transplant patients
- Determine the presence of blood clots, cysts, fluid or fat accumulation in tissues, hemorrhage, and infarctions
- Determine vascular complications of pancreatitis, venous thrombosis, or pseudoaneurysm

- Differentiate aortic aneurysms from tumors near the aorta
- Differentiate liver tumors from liver abnormalities, such as cysts, cavernous hemangiomas, and hepatic amebic abscesses
- Evaluate postoperative angioplasty sites and bypass grafts
- Monitor and evaluate the effectiveness of medical or surgical interventions and the course of the disease

POTENTIAL DIAGNOSIS

Normal findings in

- Normal anatomic structures, soft tissue density, and biochemical constituents of body tissues, including blood flow

Abnormal findings in

- Acute tubular necrosis
- Aneurysm
- Cholangitis
- Glomerulonephritis
- Hydronephrosis
- Internal bleeding
- Masses, lesions, infections, or inflammations
- Renal vein thrombosis
- Vena cava obstruction

CRITICAL FINDINGS

- Acute GI bleed
- Aortic aneurysm
- Infection
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP,

Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized.

Other considerations

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the abdominal organs and structures.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex,

anesthetics, contrast medium, or sedatives. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.

- ▶ Obtain a history of the patient's gastrointestinal, genitourinary, and hepatobiliary systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- ▶ Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- ▶ Tell the patient to expect to hear loud banging from the scanner and possibly

to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Injection of the contrast is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; cardiac arrhythmias; hematoma **related to blood leakage into the tissue following needle insertion**; bleeding from the puncture site **related to a bleeding disorder**; or **the effects of natural products and medications known to act as blood thinners**; vascular or nerve injury **that might occur if the needle strikes a nerve or nearby blood vessel**; or infection **that might occur if bacteria from the skin surface is introduced at the puncture site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the

patient to remain still throughout the procedure because movement produces unreliable results.

- ▶ Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
- ▶ Establish IV fluid line for the injection IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Assist the patient onto the examination table and into the appropriate position for imaging to begin.
- ▶ Imaging can begin shortly after the injection, if contrast is used.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the images are taken and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.

- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may

be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography abdomen, BUN, CT abdomen, creatinine, GI blood loss scan, KUB study, US abdomen, and US liver and biliary system.
- ▶ Refer to the Gastrointestinal, Genitourinary, and Hepatobiliary systems tables at the end of the book for related tests by body system.

Magnetic Resonance Imaging, Brain

SYNONYM/ACRONYM: Brain MRI.

COMMON USE: To visualize and assess intracranial abnormalities related to tumor, bleeding, lesions, and infarct such as stroke.

AREA OF APPLICATION: Brain area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio waves to produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic

field, the hydrogen atoms absorb the radio waves and change their position. This change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of pathological lesions of the brain in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or

tunnel; open MRI equipment has no sides and provides an alternative for people who suffer from claustrophobia, pediatric patients, or patients who are obese. IV gadolinium-based contrast media may be used to better visualize the vessels and tissues in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

Standard brain MRI can distinguish solid, cystic, and hemorrhagic components of lesions. This procedure is done to aid in the diagnosis of intracranial abnormalities, including tumors, ischemia, infection, and multiple sclerosis, and in assessment of brain maturation in pediatric patients. Rapidly flowing blood on spin-echo MRI appears as an absence of signal or a void in the vessel's lumen. Blood flow can be evaluated in the cavernous and carotid arteries. Contrast-enhanced imaging is effective for enhancing differences between normal and abnormal tissues. Aneurysms may be diagnosed without traditional iodine-based contrast angiography, and old clotted blood in the walls of the aneurysm appear white. MRI uses the noniodinated contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV.

Functional MRI (fMRI) is a neuroimaging application of MRI used to study how the brain is working. It identifies changes in blood flow, reflected by changes in the level of blood oxygenation, in response to activity. fMRI can identify metabolic changes in normal, diseased, or injured brain tissue. It is also used in research to study which parts of the brain are responsible for speech, physical movement, thought, and sensations; this type

of research is also called brain mapping that has significant implications in understanding and managing the effects of stroke, brain tumors, and diseases like Alzheimer's. fMRI is based on the blood oxygen level-dependent (BOLD) contrast mechanism that takes advantage of the inherent paramagnetic quality of deoxyhemoglobin. In a properly performed study, the patient is asked to perform a task; the MRI scanner detects changes in the signal strength of brain water protons produced as blood oxygen levels change, and the corresponding strength of the natural paramagnetic signal of deoxyhemoglobin changes.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***
-  Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal

dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.

-  Patients with cardiac pacemakers that can be deactivated by MRI.
-  Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet, ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet that can inactivate, move, or shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys can become dangerous projectiles.
-  Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the

patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause burns to the skin ***related to energy conducted through the metal which is converted to heat during the MRI***. Other metallic objects on the skin may also cause burns.

-  Patients who are claustrophobic.

INDICATIONS

- Detect and locate brain tumors
- Detect cause of cerebrovascular accident, cerebral infarct, or hemorrhage
- Detect cranial bone, face, throat, and neck soft tissue lesions
- Evaluate the cause of seizures, such as intracranial infection, edema, or increased intracranial pressure
- Evaluate cerebral changes associated with dementia
- Evaluate demyelinating disorders
- Evaluate intracranial infections
- Evaluate optic and auditory nerves
- Evaluate the potential causes of headache, visual loss, and vomiting
- Evaluate shunt placement and function in patients with hydrocephalus
- Evaluate the solid, cystic, and hemorrhagic components of lesions
- Evaluate vascularity of the brain and vascular integrity
- Monitor and evaluate the effectiveness of medical or surgical interventions, chemotherapy, radiation therapy, and the course of disease

POTENTIAL DIAGNOSIS

Normal findings in

- Normal anatomic structures, soft tissue density, blood flow rate, face, nasopharynx, neck, tongue, and brain

Abnormal findings in

- Abscess
- Acoustic neuroma
- Alzheimer's disease
- Aneurysm

- Arteriovenous malformation
- Benign meningioma
- Cerebral aneurysm
- Cerebral infarction
- Craniopharyngioma or meningioma
- Granuloma
- Intraparenchymal hematoma or hemorrhage
- Lipoma
- Metastasis
- Multiple sclerosis
- Optic nerve tumor
- Parkinson's disease
- Pituitary microadenoma
- Subdural empyema
- Ventriculitis

CRITICAL FINDINGS

- Abscess
- Cerebral aneurysm
- Cerebral infarct
- Hydrocephalus
- Skull fracture or contusion
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical

finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized.

Other considerations

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the brain.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.
- ▶ Obtain a history of the patient's cardiovascular and neuromuscular systems, symptoms, and results of

previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.

- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- ▶ Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department, usually by an HCP who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- ▶ Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.

- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include Alzheimer's disease markers, angiography of the carotids, BUN, CSF analysis, CT brain, creatinine, EMG, evoked brain potentials, and PET brain.
- ▶ Refer to the Cardiovascular and Musculoskeletal systems tables at the end of the book for related tests by body system.

Magnetic Resonance Imaging, Breast

SYNONYM/ACRONYM: Breast MRI.

COMMON USE: To visualize and assess abnormalities in breast tissue to assist in evaluating structural abnormalities related to diagnoses such as cancer, abscess, and cysts.

AREA OF APPLICATION: Breast area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio waves to produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the hydrogen atoms absorb the radio waves and change their position. This change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of the breast in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or tunnel; open MRI equipment has no sides and

provides an alternative for people who suffer from claustrophobia, pediatric patients, or patients who are obese. IV gadolinium-based contrast media may be used to better visualize the vessels and tissues in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

MRI imaging of the breast is not a replacement for traditional mammography, ultrasound, or biopsy. This examination is extremely helpful in evaluating mammogram abnormalities and identifying early breast cancer in women at high risk. High-risk women include those who have had breast cancer, have an abnormal mutated breast cancer gene (BRCA1 or BRCA2), or have a mother or sister who has been diagnosed with breast cancer. Breast MRI is used most commonly in high-risk women when findings of a mammogram or ultrasound are inconclusive because of dense breast tissue or there is a suspected abnormality that requires further evaluation. MRI is also an excellent examination in the augmented breast, including both the breast implant

and the breast tissue surrounding the implant. This same examination is also useful for staging breast cancer and determining the most appropriate treatment. MRI uses the noniodinated paramagnetic contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance contrast differences between normal and abnormal tissues.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***
- ◆ Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²) because use of GBCAs is contraindicated. Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.
- ◆ Patients with cardiac pacemakers that can be deactivated by MRI.
- ◆ Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet, ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet that can inactivate, move, or shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys can become dangerous projectiles.
- ◆ Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause burns to the skin ***related to energy conducted through the metal which is converted to heat during the MRI.*** Other metallic objects on the skin may also cause burns.
- ◆ Patients who are claustrophobic.

INDICATIONS

- Evaluate breast implants
- Evaluate dense breasts
- Evaluate for residual cancer after lumpectomy
- Evaluate inverted nipples
- Evaluate small abnormalities
- Evaluate tissue after lumpectomy or mastectomy
- Evaluate women at high risk for breast cancer

POTENTIAL DIAGNOSIS

Normal findings in

- Normal anatomic structures, soft tissue density, and blood flow rate

Abnormal findings in

- Breast abscess or cyst
- Breast cancer
- Breast implant rupture
- Hematoma
- Soft tissue masses
- Vascular abnormalities

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized.

Other considerations

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.
- The procedure can be nonspecific; the examination is unable to

image calcifications that can indicate breast cancer, and there may be difficulty distinguishing between cancerous and noncancerous tumors.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the breast.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- ▶ Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional

supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in an MRI department by a health-care provider (HCP) who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that the technologist will place him or her in a prone position on a special imaging table in a large cylindrical scanner.
- ▶ Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Injection of the contrast is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; cardiac arrhythmias; hematoma **related to blood leakage into the tissue following needle insertion**; bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; vascular or nerve injury **that might occur if the needle strikes a nerve or nearby blood vessel**; or infection **that might**

occur if bacteria from the skin surface is introduced at the puncture site.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
- ▶ Establish IV fluid line for the injection of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Assist the patient onto the examination table, designed for breast imaging, and into the appropriate position for imaging to begin.
- ▶ Imaging can begin shortly after the injection, if contrast is used.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the images are taken and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.

- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of breast self-examination, mammography, MRI breast, or other cancer screening procedures should be

made after consultation between the patient and HCP. The American Cancer Society (ACS) recommends breast examinations be performed every 3 yr for women between the ages of 20 and 39 yr and annually for women over 40 yr of age; annual mammograms should be performed on women 40 yr and older as long as they are in good health. The ACS also recommends annual MRI testing for women at high risk of developing breast cancer. Genetic testing for inherited mutations (BRCA1 and BRCA2) associated with increased risk of developing breast cancer may be ordered for women at risk. The test is performed on a blood specimen. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy breast, bone scan, BUN, cancer antigens, CT thorax, creatinine, ductography, mammogram, stereotactic biopsy breast, and US breast.
- ▶ Refer to the Reproductive System table at the end of the book for related tests by body system.

Magnetic Resonance Imaging, Chest

SYNONYM/ACRONYM: Chest MRI.

COMMON USE: To visualize and assess pulmonary and cardiovascular structures toward diagnosing tumor, masses, aneurysm, infarct, air, fluid, and evaluate the effectiveness of medical, and surgical interventions.

AREA OF APPLICATION: Chest/thorax.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio waves to produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the hydrogen atoms absorb the radio waves and change their position. This change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of the chest in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or tunnel; open MRI equipment has no sides and provides an alternative for people who suffer from claustrophobia, pediatric patients, or patients who are obese. IV gadolinium-based contrast media may be used to better visualize the vessels and tissues in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

Chest MRI scanning is performed to assist in diagnosing

abnormalities of cardiovascular and pulmonary structures. Two special techniques are available for evaluation of cardiovascular structures. One is the electrocardiograph (ECG)-gated multislice spin-echo sequence, used to diagnose anatomic abnormalities of the heart and aorta, and the other is the ECG-referenced gradient refocused sequence used to diagnose heart function and analyze blood flow patterns.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***
- ◆ Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²) because use of GBCAs is contraindicated. Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh

the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.

-  Patients with cardiac pacemakers that can be deactivated by MRI.
-  Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet, ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet that can inactivate, move, or shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys can become dangerous projectiles.
-  Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause

burns to the skin *related to energy conducted through the metal which is converted to heat during the MRI*. Other metallic objects on the skin may also cause burns.

-  Patients who are claustrophobic.

INDICATIONS

- Confirm diagnosis of cardiac and pericardiac masses
- Detect aortic aneurysms
- Detect myocardial infarction and cardiac muscle ischemia
- Detect pericardial abnormalities
- Detect pleural effusion
- Detect thoracic aortic diseases
- Determine blood, fluid, or fat accumulation in tissues, pleuritic space, or vessels
- Determine cardiac ventricular function
- Differentiate aortic aneurysms from tumors near the aorta
- Evaluate cardiac chambers and pulmonary vessels
- Evaluate postoperative angioplasty sites and bypass grafts
- Identify congenital heart diseases
- Monitor and evaluate the effectiveness of medical or surgical therapeutic regimen

POTENTIAL DIAGNOSIS

Normal findings in

- Normal heart and lung structures, soft tissue, and function, including blood flow rate

Abnormal findings in

- Aortic dissection
- Congenital heart diseases, including pulmonary atresia, aortic coarctation, agenesis of the pulmonary artery, and transposition of the great vessels
- Constrictive pericarditis
- Intramural and periaortic hematoma

- Myocardial infarction
- Pericardial hematoma or effusion
- Pleural effusion

CRITICAL FINDINGS

- Aortic aneurysm
- Aortic dissection
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is

given before the study or an open MRI is utilized.

Other considerations

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing organs and structures inside the chest.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.
- ▶ Obtain a history of the patient's cardiovascular and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- ▶ Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine possibility of pregnancy in perimenopausal women.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department, usually by an HCP who specializes in these procedures, with support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- ▶ Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphores (flickering lights in the visual field); these will stop when the procedure is over.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Injection of the contrast is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; cardiac arrhythmias; hematoma **related to blood leakage into the tissue following needle insertion**; bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; vascular or nerve injury **that might occur if the needle strikes**

- a nerve or nearby blood vessel**; or infection **that might occur if bacteria from the skin surface is introduced at the puncture site**.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
- ▶ Apply MRI-safe electrodes to the appropriate sites if an electrocardiogram or respiratory gating is to be performed in conjunction with the scan.
- ▶ Establish IV fluid line for the injection IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Administer an anti-anxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Assist the patient onto the examination table and into the appropriate position for imaging to begin.
- ▶ Imaging can begin shortly after the injection, if contrast is used.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the images are taken and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of

- abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include AST, BNP, blood gases, blood pool imaging, BUN, chest x-ray, CT cardiac scoring, CT thorax, CRP, CK and isoenzymes, creatinine, echocardiography, exercise stress test, Holter monitor, myocardial infarct scan, myocardial perfusion heart scan, myoglobin, pleural fluid analysis, PET scan of the heart, and troponins.
- ▶ Refer to the Cardiovascular and Respiratory systems tables at the end of the book for related tests by body system.

Magnetic Resonance Imaging, Musculoskeletal

SYNONYM/ACRONYM: Musculoskeletal (knee, shoulder, hand, wrist, foot, elbow, hip, spine) MRI.

COMMON USE: To visualize and assess bones, joints, and surrounding structures to assist in diagnosing defects, cysts, tumors, and fracture.

AREA OF APPLICATION: Bones, joints, soft tissues.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio waves to produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the hydrogen atoms absorb the radio waves and change their position. This change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of bones and joints in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or tunnel; open MRI equipment has no sides and provides an alternative for people who suffer from claustrophobia, pediatric patients, or patients who are obese. IV gadolinium-based contrast media may be used to better visualize the vessels and tissues in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

Musculoskeletal MRI is performed to assist in diagnosing abnormalities of bones and joints and surrounding soft tissue

structures, including cartilage, synovium, ligaments, and tendons. MRI eliminates the risks associated with exposure to x-rays and causes no harm to cells. Contrast-enhanced imaging is effective for evaluating scarring from previous surgery, vascular abnormalities, and differentiation of metastases from primary tumors. MRI uses the noniodinated paramagnetic contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance differences between normal and abnormal tissues.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***
- ◆ Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the

studies outweigh the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.

-  Patients with cardiac pacemakers that can be deactivated by MRI.
-  Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet, ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet that can inactivate, move, or shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys can become dangerous projectiles.
-  Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause burns to the skin *related to energy conducted through the metal*

which is converted to heat during the MRI. Other metallic objects on the skin may also cause burns.

-  Patients who are claustrophobic.

INDICATIONS

- Confirm diagnosis of osteomyelitis
- Detect avascular necrosis of the femoral head or knee
- Detect benign and cancerous tumors and cysts of the bone or soft tissue
- Detect bone infarcts in the epiphyseal or diaphyseal sites
- Detect changes in bone marrow
- Detect tears or degeneration of ligaments, tendons, and menisci resulting from trauma or pathology
- Determine cause of low back pain, including herniated disk and spinal degenerative disease
- Differentiate between primary and secondary malignant processes of the bone marrow
- Differentiate between a stress fracture and a tumor
- Evaluate meniscal detachment of the temporomandibular joint

POTENTIAL DIAGNOSIS

Normal findings in

- Normal bones, joints, and surrounding tissue structures; no articular disease, bone marrow disorders, tumors, infections, or trauma to the bones, joints, or muscles

Abnormal findings in

- Avascular necrosis of femoral head or knee, as found in Legg-Calvé-Perthes disease
- Bone marrow disease, such as Gaucher's disease, aplastic anemia, sickle cell disease, or polycythemia
- Degenerative spinal disease, such as spondylosis or arthritis
- Fibrosarcoma
- Hemangioma (muscular or osseous)
- Herniated disk
- Infection

- Meniscal tears or degeneration
- Osteochondroma
- Osteogenic sarcoma
- Osteomyelitis
- Rotator cuff tears
- Spinal stenosis
- Stress fracture
- Synovitis
- Tumor

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized.

Other considerations

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing bones, muscles, and joints.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- ▶ Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department, usually by a health-care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- ▶ Tell the patient to expect to hear loud banging from the scanner and possibly

to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Injection of the contrast is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; cardiac arrhythmias; hematoma **related to blood leakage into the tissue following needle insertion**; bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; vascular or nerve injury **that might occur if the needle strikes a nerve or nearby blood vessel**; or infection **that might occur if bacteria from the skin surface is introduced at the puncture site**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the

gown, robe, and foot coverings provided.

- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
- ▶ Establish IV fluid line for the injection of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Assist the patient onto the examination table and into the appropriate position for imaging to begin.
- ▶ Imaging can begin shortly after the injection, if contrast is used.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the images are taken and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting, if contrast medium was used.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or

abdominal pain. Immediately report symptoms to the appropriate HCP.

- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to anticipated chronic pain resulting from joint inflammation, impairment in mobility, musculoskeletal deformity, and loss of independence. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org) or for the Arthritis Foundation (www.arthritis.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include anticyclic citrullinated antibodies, ANA, arthrogram, arthroscopy, bone mineral densitometry, bone scan, BUN, CRP, CT spine, creatinine, ESR, radiography of the bone, synovial fluid analysis, RF, and vertebroplasty.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Magnetic Resonance Imaging, Pancreas

M

SYNONYM/ACRONYM: Pancreatic MRI.

COMMON USE: To visualize and assess the pancreas for structural defects, tumor, masses, staging cancer, and evaluating the effectiveness of medical and surgical interventions.

AREA OF APPLICATION: Pancreatic/upper abdominal area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio

waves to produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the hydrogen atoms absorb

the radio waves and change their position. This change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of the pancreas in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or tunnel; open MRI equipment has no sides and provides an alternative for people who suffer from claustrophobia, pediatric patients, or patients who are obese. IV gadolinium-based contrast media may be used to better visualize the vessels and tissues in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

MRI of the pancreas is employed to evaluate small pancreatic adenocarcinomas, islet cell tumors, ductal abnormalities and calculi, or parenchymal abnormalities. A T1-weighted, fat-saturation series of images is probably best for evaluating the pancreatic parenchyma. This sequence is ideal for showing fat planes between the pancreas and peripancreatic structures and for identifying abnormalities such as fatty infiltration of the pancreas, hemorrhage, adenopathy, and carcinomas. T2-weighted images are most useful for depicting intrapancreatic or peripancreatic fluid collections, pancreatic neoplasms, and calculi. Imaging sequences can be adjusted to display fluid in the biliary tree and pancreatic ducts. MRI

uses the noniodinated paramagnetic contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance contrast differences between normal and abnormal tissues.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***
-  Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.
-  Patients with cardiac pacemakers that can be deactivated by MRI.
-  Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet,

ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet that can inactivate, move, or shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys, can become dangerous projectiles.

-  Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause burns to the skin **related to energy conducted through the metal which is converted to heat during the MRI**. Other metallic objects on the skin may also cause burns.
-  Patients who are claustrophobic.

INDICATIONS

- Detect pancreatic fatty infiltration, hemorrhage, and adenopathy
- Detect a pancreatic mass
- Detect pancreatitis
- Detect primary or metastatic tumors of the pancreas and provide cancer staging

- Detect soft tissue abnormalities
- Determine vascular complications of pancreatitis, venous thrombosis, or pseudoaneurysm
- Differentiate tumors from other abnormalities, such as cysts, cavernous hemangiomas, and pancreatic abscesses
- Monitor and evaluate the effectiveness of medical or surgical interventions and course of disease

POTENTIAL DIAGNOSIS

Normal findings in

- Normal anatomic structures and soft tissue density and biochemical constituents of the pancreatic parenchyma, including blood flow

Abnormal findings in

- Islet cell tumor
- Metastasis
- Pancreatic duct obstruction or calculi
- Pancreatic fatty infiltration, hemorrhage, and adenopathy
- Pancreatic mass
- Pancreatitis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized.

Other considerations

- If contrast medium is allowed to seep deep into the muscle

tissue, vascular visualization will be impossible.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the pancreas, organs, and structures inside the abdomen.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.
- ▶ Obtain a history of the patient's endocrine and hepatobiliary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- ▶ Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional

supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in an MRI department by a health-care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- ▶ Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Injection of the contrast is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; cardiac arrhythmias; hematoma **related to blood leakage into the tissue following needle insertion**; bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; vascular or nerve injury **that might occur if the needle strikes a nerve or nearby blood vessel**; or infection **that might occur if bacteria**

from the skin surface is introduced at the puncture site.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
- ▶ Establish IV fluid line for the injection IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Assist the patient onto the examination table and into the appropriate position for imaging to begin.
- ▶ Imaging can begin shortly after the injection, if contrast is used.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the images are taken and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.

- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include amylase, angiography of the abdomen, BUN, calcitonin, cholangiopancreatography endoscopic retrograde, CT abdomen, creatinine, hepatobiliary scan, 5-hydroxyindoleacetic acid, lipase, peritoneal fluid analysis, US liver and biliary system, and US pancreas.
- ▶ Refer to the Endocrine and Hepatobiliary systems tables at the end of the book for related tests by body system.

Magnetic Resonance Imaging, Pelvis

SYNONYM/ACRONYM: Pelvis MRI.

COMMON USE: To visualize and assess the pelvis and surrounding structure for tumor, masses, staging cancer, and inflammation and to evaluate the effectiveness of medical and surgical interventions.

AREA OF APPLICATION: Pelvic area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio waves to produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the hydrogen atoms absorb the radio waves and change their position. This change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of the pelvic area in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or tunnel; open MRI

equipment has no sides and provides an alternative for people who suffer from claustrophobia, pediatric patients, or patients who are obese. IV gadolinium-based contrast media may be used to better visualize the vessels and tissues in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

Pelvic MRI is performed to assist in diagnosing abnormalities of the pelvis and associated structures. Contrast-enhanced MRI is effective for evaluating metastases from primary tumors. MRI is highly effective for depicting small-volume peritoneal tumors, carcinomatosis, and peritonitis and for determining the response to surgical and chemical therapies. MRI uses the noniodinated paramagnetic contrast medium gadopentetate dimeglumine (Magnevist), which is administered IV to enhance differences between normal and abnormal tissues. Oral and rectal contrast administration may be used to isolate the bowel from adjacent pelvic organs and improve organ visualization.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***
-  Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.
-  Patients with cardiac pacemakers that can be deactivated by MRI.
-  Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet, ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet that can inactivate, move, or shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys can become dangerous projectiles.
-  Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause burns to the skin ***related to energy conducted through the metal which is converted to heat during the MRI.*** Other metallic objects on the skin may also cause burns.
-  Patients who are claustrophobic.

INDICATIONS

- Detect cancer (primary or metastatic tumors of ovary, prostate, uterus, and bladder) and provide cancer staging
- Detect pelvic vascular diseases
- Detect peritonitis
- Detect soft tissue abnormalities
- Determine blood clots, cysts, fluid or fat accumulation in tissues, hemorrhage, and infarctions

- Differentiate tumors from tissue abnormalities, such as cysts, cavernous hemangiomas, and abscesses
- Monitor and evaluate the effectiveness of medical or surgical interventions and course of the disease

POTENTIAL DIAGNOSIS

Normal findings in

- Normal pelvic structures and soft tissue density and biochemical constituents of pelvic tissues, including blood flow

Abnormal findings in

- Adenomyosis
- Ascites
- Fibroids
- Masses, lesions, infections, or inflammations
- Peritoneal tumor or carcinomatosis
- Peritonitis
- Pseudomyxoma peritonei

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized.

Other considerations

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the pelvis and surrounding structures.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.

- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Magnetic Resonance Imaging, Pituitary

M

SYNONYM/ACRONYM: Pituitary MRI, MRI of the parasellar region.

COMMON USE: To visualize and assess the pituitary and surrounding structures of the brain for lesions, hemorrhage, cysts, abscess, tumors, cancer, and infection.

AREA OF APPLICATION: Brain/pituitary area.

CONTRAST: Can be done with or without IV contrast medium (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio waves to

produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the hydrogen atoms absorb

the radio waves and change their position. This change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of the vessels in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or tunnel; open MRI equipment has no sides and provides an alternative for people who suffer from claustrophobia, pediatric patients, or patients who are obese. IV gadolinium-based contrast media may be used to better visualize the pituitary gland and parasellar region in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

Pituitary MRI shows the relationship of pituitary lesions to the optic chiasm and cavernous sinuses. MRI has the capability of distinguishing the solid, cystic, and hemorrhagic components of lesions. Rapidly flowing blood on spin-echo MRI appears as an absence of signal or a void in the vessel's lumen. Blood flow can be evaluated in the cavernous and carotid arteries. Suprasellar aneurysms may be diagnosed without angiography, and old clotted blood in the walls of the aneurysms appears white. MRI uses the noniodinated paramagnetic contrast medium gadopentetate dimeglumine (Magnevist) that is administered IV to enhance contrast differences between normal and abnormal tissues.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of the MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***
- ◆ Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using non-contrast-enhanced diagnostic studies.
- ◆ Patients with cardiac pacemakers that can be deactivated by MRI.
- ◆ Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet, ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and

health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet that can inactivate, move, or shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys can become dangerous projectiles.

- ◆ Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause burns to the skin **related to energy conducted through the metal which is converted to heat during the MRI**. Other metallic objects on the skin may also cause burns.
- ◆ Patients who are claustrophobic.

INDICATIONS

- Detect microadenoma or macroadenoma of the pituitary
- Detect parasellar abnormalities
- Detect tumors of the pituitary
- Evaluate potential cause of headache, visual loss, and vomiting
- Evaluate the solid, cystic, and hemorrhagic components of lesions
- Evaluate vascularity of the pituitary
- Monitor and evaluate the effectiveness of medical or surgical interventions and course of disease

POTENTIAL DIAGNOSIS

Normal findings in

- Normal anatomic structures, density, and biochemical constituents of the pituitary, including blood flow

Abnormal findings in

- Abscess
- Aneurysm
- Choristoma
- Craniopharyngioma or meningioma
- Empty sella
- Granuloma
- Infarct or hemorrhage
- Macroadenoma or microadenoma
- Metastasis
- Parasitic infection

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study or an open MRI is utilized.

Other considerations

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ◆ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the pituitary gland and surrounding brain tissue.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.
- ▶ Obtain a history of the patient's cardiovascular and endocrine systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- ▶ Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Inform the patient the procedure is performed in an MRI department by a health-care provider (HCP) specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

- ▶ Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- ▶ Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Instruct the patient to remove jewelry and all other metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

- Injection of the contrast is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; cardiac arrhythmias; hematoma **related to blood leakage into the tissue following needle insertion**; bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; vascular or nerve injury **that might occur if the needle strikes a nerve or nearby blood vessel**; or infection **that might occur if bacteria from the skin surface is introduced at the puncture site**.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
- ▶ Establish IV fluid line for the injection IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Assist the patient onto the examination table and into the appropriate position for imaging to begin.
- ▶ Imaging can begin shortly after the injection, if contrast is used.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the images are taken and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH and challenge tests, angiography brain, BUN, cortisol and challenge tests, CT brain, creatinine, EEG, MRI brain, and PET brain.
- ▶ Refer to the Cardiovascular and Endocrine systems tables at the end of the book for related tests by body system.

Magnetic Resonance Venography

SYNONYM/ACRONYM: MRV.

COMMON USE: To visualize and assess blood flow in diseased and normal veins toward diagnosis of vascular disease and to monitor and evaluate therapeutic interventions.

AREA OF APPLICATION: Vascular.

CONTRAST: Can be done with or without IV contrast (gadolinium).

DESCRIPTION: Magnetic resonance imaging (MRI) is very useful when the area of interest is soft tissue. The technology does not involve radiation exposure and is considered safer than other imaging methods such as radiographs and computed tomography (CT). MRI uses a magnet and radio waves to produce an energy field that can be displayed as an image of the anatomic area of interest based on the water content of the tissue. The magnetic field causes the hydrogen atoms in tissue to line up, and when radio waves are directed toward the magnetic field, the hydrogen atoms absorb the radio waves and change their position. This change in the energy field is detected by the equipment, and an image is generated by the equipment's computer system. MRI produces cross-sectional images of the vessels in multiple planes without the use of ionizing radiation or the interference of bone or surrounding tissue. Images can be obtained in two-dimensional (series of slices) or three-dimensional sequences. Standard or closed MRI equipment has the appearance of an open tube or tunnel; open MRI equipment has no sides and provides an

alternative for people who suffer from claustrophobia, pediatric patients, or patients who are obese. IV gadolinium-based contrast media may be used to better visualize the vessels and tissues in the area of interest. Clear, high-quality images of abnormalities and disease processes significantly improve the diagnostic value of the study.

Magnetic resonance venography (MRV) is an accurate, noninvasive technique used to detect deep vein thrombosis. This application of MRI provides images of blood flow in diseased and normal veins. In patients who are allergic to iodinated contrast medium, MRV is used in place of venography or CT venography. MRV is particularly useful for visualizing vascular abnormalities, thrombosis, and other pathology. MRV can be accomplished with a contrast-enhanced (CE) or non-contrast-enhanced method. Special imaging sequences allow the visualization of moving blood within the venous system. Two common techniques to obtain images of flowing blood are time-of-flight (TOF) and steady-state free precession (SSFP). In TOF imaging, incoming blood makes

the vessels appear bright, and surrounding tissue is suppressed. SSFP is generally used for assessment of veins in the chest, abdomen, and pelvis. Although the initial evaluation of the iliac and lower extremity veins is usually accomplished with sonography, MRV is more efficient in detecting venous thrombus in the pelvic and calf veins, especially in obese patients and those with chronic asymptomatic thrombus.

This procedure is contraindicated for

- 
 Patients who are pregnant or suspected of being pregnant, unless the potential benefits of MRI far outweigh the risks to the fetus and mother. ***In pregnancy, gadolinium-based contrast agents (GBCAs) cross the placental barrier, enter the fetal circulation, and pass via the kidneys into the amniotic fluid. Although no definite adverse effects of GBCA administration on the human fetus have been documented, the potential bioeffects of fetal GBCA exposure are not well understood. GBCA administration should therefore be avoided during pregnancy unless no suitable alternative imaging is possible and the benefits of contrast administration outweigh the potential risk to the fetus.***
- 
 Patients with moderate to marked renal impairment (glomerular filtration rate less than 30 mL/min/1.73 m²). Patients should be screened for renal dysfunction prior to administration. The use of GBCAs should be avoided in these patients unless the benefits of the studies outweigh the risks and if essential diagnostic information is not available using

non-contrast-enhanced diagnostic studies.

- 
 Patients with cardiac pacemakers that can be deactivated by MRI.
- 
 Patients with metal in their body, such as dental amalgams, metallic body piercing items, tattoo inks containing iron (including tattooed eyeliners), shrapnel, bullet, ferrous metal in the eye, certain ferrous metal prosthetics, valves, aneurysm clips, IUD, inner ear prostheses, or other metallic objects; these items can impair image quality. Metallic objects are also a significant safety issue for patients and health-care staff in the examination room during performance of an MRI. The MRI equipment consists of an extremely powerful magnet that can inactivate, move, or shift metallic objects inside a patient. Many metallic objects currently used in health-care procedures are made of materials that do not interfere with MRI studies; it is important for patients to provide specific information regarding medical procedures they have undergone in order to identify whether their device is safe to undergo MRI. Required information includes the date of the procedure and identification of the device. Metallic objects are not allowed inside the room with the MRI equipment because items such as watches, credit cards, and car keys, can become dangerous projectiles.
- 
 Patients with transdermal patches containing metallic components. The patch's liner contains a metal that controls absorption of the substance from the patch (e.g., drugs, nicotine, steroids, hormones). The patch may cause burns to the skin ***related to energy conducted through the metal which is converted to heat***

during the MRI. Other metallic objects on the skin may also cause burns.

- ◆ Patients who are claustrophobic.

INDICATIONS

- Detect peripheral vascular disease (PVD)
- Detect axillary vein disease
- Detect cerebral vein disease
- Detect pulmonary vein disease
- Evaluate iliac and lower-extremity vein disease
- Evaluate postoperative venous sites and bypass grafts
- Identify deep vein thrombus in postsurgical patients
- Monitor and evaluate the effectiveness of medical or surgical treatment

POTENTIAL DIAGNOSIS

Normal findings in

- Normal blood flow in the area being examined

Abnormal findings in

- Cerebral vein thrombosis
- Deep vein thrombosis
- Pulmonary emboli
- PVD
- Tumor invasion of a vein
- Vascular abnormalities
- Vein occlusion
- Vein stenosis

CRITICAL FINDINGS ◆

- Cerebral emboli
- Occlusion
- Pulmonary emboli
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary

among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Patients with extreme cases of claustrophobia, unless sedation is given before the study.

Other considerations

- If contrast medium is allowed to seep deep into the muscle tissue, vascular visualization will be impossible.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ◆ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ◆ **Patient Teaching:** Inform the patient this procedure can assist in assessing the vascular system.

- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives. Patients with a known hypersensitivity to contrast medium may benefit from premedication with corticosteroids and diphenhydramine.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures. Obtain a history of renal dysfunction if the use of GBCA is anticipated.
- ▶ Ensure the results of BUN, creatinine, and eGFR (estimated glomerular filtration rate) are obtained if GBCA is to be used.
- ▶ Determine if the patient has ever had any device implanted into his or her body, including copper intrauterine devices, pacemakers, ear implants, and heart valves.
- ▶ Obtain occupational history to determine the presence of metal in the body, such as shrapnel or flecks of ferrous metal in the eye (which can cause retinal hemorrhage).
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient that if contrast is used, it poses no radioactive hazard and rarely produces side effects. Inform the patient the procedure is performed in an MRI department by an HCP who specializes in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ Inform the patient that the technologist will place him or her in a supine position on a flat table in a large cylindrical scanner.
- ▶ Tell the patient to expect to hear loud banging from the scanner and possibly to see magnetophosphenes (flickering lights in the visual field); these will stop when the procedure is over.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove external metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

- Injection of the contrast is an invasive procedure. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; cardiac arrhythmias; hematoma **related to blood leakage into the tissue following needle insertion**; bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; vascular or nerve injury **that might occur if the needle strikes a nerve or nearby blood vessel**; or infection **that might occur if bacteria from the skin surface is introduced at the puncture site**.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
 - ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Supply earplugs to the patient to block out the loud, banging sounds that occur during the test. Instruct the patient to communicate with the technologist during the examination via a microphone within the scanner.
- ▶ Apply MRI-safe electrodes to the appropriate sites if an electrocardiogram or respiratory gating is to be performed in conjunction with the scan.
- ▶ Establish IV fluid line for the injection IV fluids such as saline, anesthetics, contrast medium, or sedatives.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Assist the patient onto the examination table and into the appropriate position for imaging to begin.
- ▶ Imaging can begin shortly after the injection, if contrast is used.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the American Heart Association (www.americanheart.org), the NHLBI (www.nhlbi.nih.gov), or Legs for Life (www.legsforlife.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography of the body area of interest, BUN, CT angiography, creatinine, D-dimer, US arterial Doppler carotid, US venous Doppler extremity studies, and venography lower extremity studies.
- ▶ Refer to the Cardiovascular System table at the end of the book for related tests by body system.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.

Mammography

SYNONYM/ACRONYM: Breast x-ray, mammogram.

COMMON USE: To visualize and assess breast tissue and surrounding lymph nodes for cancer, inflammation, abscess, tumor, and cysts.

AREA OF APPLICATION: Breast.

CONTRAST: None.

DESCRIPTION: Mammography, an x-ray examination of the breast, is most commonly used to detect breast cancer; however, it can also be used to detect and evaluate symptomatic changes associated with other breast diseases, including mastitis, abscess, cystic changes, cysts, benign tumors, masses, and lymph nodes. In addition, mammography can be used to locate a non-palpable lesion for breast biopsy studies. While mammography cannot detect breast cancer with 100% accuracy, only about 10–15% of breast cancer cases are not detected. Recent advances in mammography technologies include full-field digital mammography (FFDM), computer-aided detection (CAD) systems, and three-dimensional (3-D) breast imaging or breast tomosynthesis. FFDM is performed in the same manner as conventional screen film mammography (SFM). The difference is that FFDM images are created by digitized signals rather than from x-ray film as with SFM. The FFDM detectors convert x-rays into electrical signals that are digitalized. The digital images can be visualized on a computer screen or printed on special paper. Computer-aided detection (CAD) systems use software to search images from SFM or FFDM for

abnormal areas of breast tissue evidenced by denseness, abnormal size, or calcifications that may indicate the presence of cancer. Abnormal areas are “marked” for further review by a radiologist. 3-D breast imaging is performed in the same manner as conventional 2-D screen film mammography (SFM). However, 3-D imaging uses equipment that rotates in an arc over the breast instead of the stationary system used in conventional SFM. The 3-D equipment generates a series of thin slices believed to produce clearer images, especially of dense breast tissue. The new technologies are becoming more frequently used in screening mammography programs across the U.S. Preliminary studies have demonstrated some improvement in detection rates, especially for some types of invasive cancer, and a reduction in recalls for additional imaging.

When a mass is detected, additional studies are performed to help differentiate the nature of the mass, as follows:

- Magnification views of the area in question
- Focal or “spot” views of the area in question, done with a specialized paddle-style compression device

- Ultrasound images of the area in question, which help differentiate between a fluid-filled cystic lesion and a solid lesion indicative of cancer or fibroadenomas.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risks to the fetus and mother.
-  Patients younger than age 25 or patients with very dense breast tissue, *because the density of the breast tissue is such that diagnostic x-rays are of limited value.*

INDICATIONS

- Differentiate between benign and neoplastic breast disease
- Evaluate breast pain, skin retraction, nipple erosion, or nipple discharge
- Evaluate known or suspected breast cancer
- Evaluate nonpalpable breast masses
- Evaluate opposite breast after mastectomy
- Monitor postoperative and post-radiation treatment status of the breast
- Evaluate size, shape, and position of breast masses

POTENTIAL DIAGNOSIS

Normal findings in

- Normal breast tissue, with no cysts, tumors, or calcifications

Abnormal findings in

- Breast calcifications
- Breast cysts or abscesses
- Breast tumors
- Hematoma resulting from trauma
- Mastitis
- Soft tissue masses
- Vascular calcification

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Application of substances such as talcum powder, deodorant, or creams to the skin of breasts or underarms, which may alter test results.
- Previous breast surgery, breast augmentation, or the presence of breast implants, which may decrease the readability of the examination.

Other considerations

- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding infants of patients who are lactating.
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

-  Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
-  **Patient Teaching:** Inform the patient this procedure can assist in assessing breast status.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's reproductive system, known or suspected breast disease, and family history of breast disease; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure. Inform the patient there may be discomfort associated with the study while the breast is being compressed, but the compression allows for better visualization of the breast tissue. Explain to the patient that the radiation dose will be kept to an absolute minimum. Inform the patient that the procedure is performed in the mammography department by a registered mammographer and takes approximately 15 to 30 min to complete.
- ▶ Inform the patient that the best time to schedule the examination is 1 week after menses, when breast tenderness is decreased.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Inform the patient not to apply deodorant, body creams, or powders on the day of the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area of examination.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

- ▶ Ensure that the patient has removed all jewelry and other metallic objects from the chest area.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown and robe provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Assist the patient to a standing or sitting position in front of the x-ray machine, which is adjusted to the level of the breasts. Position the patient's arms out of the range of the area to be imaged.
- ▶ Place breasts, one at a time, between the compression apparatus. Two images or exposures are taken of each breast. Ask the patient to hold her breath during each exposure. Additional images may be taken as requested by the radiologist before the patient leaves the mammography room.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Determine if the patient has any further questions or concerns.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Cancer Society (www.cancer.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of breast self-examination,

mammography, MRI breast, or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society (ACS) recommends breast examinations be performed every 3 yr for women between the ages of 20 and 39 yr and annually for women over 40 yr of age; annual mammograms should be performed on women 40 yr and older as long as they are in good health. The ACS also recommends annual MRI testing for women at high risk of developing breast cancer. Genetic testing for inherited mutations (BRCA1 and BRCA2) associated with increased risk of developing breast cancer may be ordered for women at risk. The test is performed on a blood specimen. The most current guidelines for breast cancer screening of the general population as well as of individuals with increased

risk are available from the American Cancer Society (www.cancer.org), the American College of Obstetricians and Gynecologists (ACOG) (www.acog.org), and the American College of Radiology (www.acr.org).

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include biopsy breast, cancer antigens, ductography, MRI breast, stereotactic biopsy breast, and US breast.
- Refer to the Reproductive System table at the end of the book for related tests by body system.

Meckel's Diverticulum Scan

SYNONYM/ACRONYM: Ectopic gastric mucosa scan, Meckel's scan, Meckel's scintigraphy.

COMMON USE: To assess, evaluate, and diagnose the cause of abdominal pain and gastrointestinal bleeding.

AREA OF APPLICATION: Abdomen.

CONTRAST: IV radioactive technetium-99m pertechnetate.

DESCRIPTION: Meckel's diverticulum scan is a nuclear medicine study performed to assist in diagnosing the cause of abdominal pain or occult gastrointestinal (GI) bleeding and to assess the presence and size of a congenital anomaly of the GI tract. After IV injection of technetium-99m pertechnetate, immediate and

delayed imaging is performed, with various views of the abdomen obtained. The radionuclide is taken up and concentrated by parietal cells of the gastric mucosa, whether located in the stomach or in a Meckel's diverticulum. Up to 25% of Meckel's diverticulum is lined internally with ectopic gastric mucosal tissue.

This tissue is usually located in the ileum and right lower quadrant of the abdomen; it secretes acid that causes ulceration of intestinal tissue, which results in abdominal pain and occult blood in stools.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of unexplained abdominal pain and GI bleeding caused by hydrochloric acid and pepsin secreted by ectopic gastric mucosa, which ulcerates nearby mucosa
- Detect sites of ectopic gastric mucosa

POTENTIAL DIAGNOSIS

Normal findings in

- Normal distribution of radionuclide by gastric mucosa at normal sites

Abnormal findings in

- Meckel's diverticulum, as evidenced by focally increased radioactive uptake in areas other than normal structures

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Retained barium from a previous radiological procedure.
- Other nuclear scans done within the preceding 24 hr.

Other considerations

- Improper injection of the radio nuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- False-positive results may occur from nondiverticular bleeding, intussusception, duplication cysts, inflammatory bowel disease, hemangioma of the bowel, and other organ infections.
- Inadequate amount of gastric mucosa within Meckel's diverticulum can affect the ability to visualize abnormalities.
- Inaccurate timing for imaging after the radionuclide injection can affect the results.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Risks associated with radiation overexposure can result from

frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ Inform the patient this procedure can assist in assessing gastrointestinal bleeding.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, but there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects.

Inform the patient that the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure, with support staff, and takes approximately 60 min. **Pediatric Considerations** Preparing children for a Meckel's diverticulum scan depends on the age of the child. Encourage parents to be truthful about what the child may experience during the procedure (e.g., they may feel a pinch or minor discomfort when the IV needle is inserted) and to use words that they know their child will understand. Toddlers and preschool-age children have a very short attention span, so the best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with the child during the procedure. Explain the importance of remaining still while the images are taken.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to take a histamine blocker, as ordered, 2 days before the study to block GI secretion.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**
- ▶ Instruct the patient to fast and refrain from fluids for 8 hr prior to the procedure. Protocols may vary among facilities.

INTRATEST:

Potential Covations:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and

medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injecting radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; hematoma **related to blood leakage into the tissue following needle insertion**; infection **that might occur if bacteria from the skin surface is introduced at the puncture site**; or nerve injury **that might occur if the needle strikes a nerve**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in a supine position on a flat table with foam wedges, which help maintain position and immobilization.

- ▶ IV radionuclide is administered, and the abdomen is scanned immediately to screen for vascular lesions. Images are taken in various positions every 5 min for the next hour.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Unless contraindicated, advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Instruct the patient to resume usual diet, fluids, and medications, as directed by the HCP.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.

- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ **Nutritional Considerations:** A low-fat, low-cholesterol, and low-sodium diet should be consumed to reduce current disease processes. High fat consumption increases the amount of bile acids in the colon and should be avoided.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss

- the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
 - ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include barium swallow, colonoscopy, CT abdomen, CT pelvis, esophageal manometry, EGD, fecal analysis, gastric acid stimulation, gastric emptying scan, gastrin stimulation, GI blood loss, MRI abdomen, MRI pelvis, and upper GI series.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

M

Mediastinoscopy

SYNONYM/ACRONYM: N/A.

COMMON USE: To visualize and assess structures under the mediastinum to assist in obtaining biopsies for diagnosing and staging cancer and to evaluate the effectiveness of therapeutic interventions.

AREA OF APPLICATION: Mediastinum.

CONTRAST: None.

DESCRIPTION: Mediastinoscopy provides direct visualization of the structures that lie beneath the mediastinum, which is the area

behind the sternum and between the lungs. The test is performed under general anesthesia by means of a mediastinoscope

inserted through a surgical incision at the suprasternal notch. Structures that can be viewed include the trachea, the esophagus, the heart and its major vessels, the thymus gland, and the lymph nodes that receive drainage from the lungs. The procedure is performed primarily to visualize and obtain biopsy specimens of the mediastinal lymph nodes and to determine the extent of metastasis into the mediastinum for the determination of treatment planning in cancer patients.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients who have had a previous mediastinoscopy, *because scarring can make insertion of the scope and biopsy of lymph nodes difficult.*
-  Patients who have superior vena cava obstruction, *because this condition causes increased venous collateral circulation in the mediastinum.*

INDICATIONS

- Confirm radiological evidence of a thoracic infectious process of an indeterminate nature, coccidioidomycosis, or histoplasmosis
- Confirm radiological or cytological evidence of carcinoma or sarcoidosis
- Detect Hodgkin's disease
- Detect metastasis into the anterior mediastinum or extrapleurally into the chest
- Determine stage of known bronchogenic carcinoma, as indicated

by the extent of mediastinal lymph node involvement

- Evaluate a patient with signs and symptoms of obstruction of mediastinal lymph flow and a history of head or neck cancer to determine recurrence or spread

POTENTIAL DIAGNOSIS

Normal findings in

- Normal appearance of mediastinal structures
- No abnormal lymph node tissue

Abnormal findings in

- Bronchogenic carcinoma
- Coccidioidomycosis
- Granulomatous infections
- Histoplasmosis
- Hodgkin's disease
- *Pneumocystis jiroveci* (formerly *P. carinii*)
- Sarcoidosis
- Tuberculosis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing structure in the middle of the chest.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.

- ▶ Obtain a history of the patient's immune and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Ensure that the results of blood typing and crossmatching are obtained and recorded before the procedure in the event that an emergency thoracotomy is required.
- ▶ Note any recent procedures that can interfere with test results. Ensure that this procedure is performed before an upper gastrointestinal study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that prophylactic antibiotics may be administered prior to the procedure. Address concerns about pain related to the procedure and explain that a general anesthesia will be administered to promote relaxation and reduce discomfort prior to the mediastinoscopy. Explain that some pain may be experienced after the test. Meperidine (Demerol) or morphine may be given as a sedative. Inform the patient that the procedure is performed in the operating room by a health-care provider (HCP) specializing in this procedure, with support staff, and usually takes 30 to 60 min to complete.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Instruct the patient to remove jewelry and external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient that to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least

2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant.

- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Complications of the procedure may include bleeding and cardiac arrhythmias.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure that the patient has complied with food, fluids, and medication restrictions for 8 hr prior to the procedure.
 - ▶ Ensure that the patient has removed jewelry and external metallic objects from the area to be examined prior to the procedure.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Have emergency equipment readily available.
 - ▶ Instruct the patient to void prior to the procedure and change into the gown, robe, and foot coverings provided.
 - ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
 - ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
 - ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.

- ▶ Avoid using morphine sulfate in patients with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- ▶ Place the patient in the supine position. General anesthesia is administered via an endotracheal tube.
- ▶ An incision is made at the suprasternal notch, and a path for the mediastinoscope is made using finger dissection. The lymph nodes can be palpated at this time. The lymph nodes on the right side of the mediastinum are most accessible and safest to biopsy by mediastinoscopy; the lymph nodes on the left side are more difficult to explore and biopsy because of their proximity to the aorta. Biopsy specimens of nodes on the left side of the mediastinum may need to be obtained by mediastinotomy, which involves performing a left anterior thoracotomy.
- ▶ Place tissue samples in properly labeled specimen containers, and promptly transport the specimen to the laboratory for processing and analysis.
- ▶ The scope is removed, and the incision is closed.
- ▶ Observe/assess the incision site for bleeding, inflammation, or hematoma formation.
- ▶ If the patient is stable and if no further surgery is immediately indicated, the patient is extubated.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Do not allow the patient to eat or drink for 12 to 24 hr.
- ▶ Instruct the patient to resume normal activity, medication, and diet in 24 hr or as tolerated after the examination, unless otherwise indicated.
- ▶ The patient should remain in a semi-Fowler's position on either side until vital signs revert to preprocedure levels.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Monitor intake and output, at least every 8 hr. Compare with baseline values.

Notify the HCP if temperature changes. Protocols may vary among facilities.

- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Emphasize that any excessive bleeding; difficulty breathing; excessive coughing after biopsy; fever; or redness, swelling, or pain of the incisional area must be reported to the HCP immediately.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACE, β_2 -microglobulin, biopsy liver, biopsy lung, biopsy lymph node, blood gases, bronchoscopy, carbon dioxide, chest x-ray, CBC, CBC WBC count and differential, CT thoracic, culture and smear mycobacteria, gallium scan, Gram stain, laparoscopy abdominal, LAP, liver and spleen scan, lung perfusion scan, lung ventilation scan, lymphangiogram, MRI chest, platelet count, pleural fluid analysis, PFT, and TB skin tests.

Metanephrines

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in the diagnosis of cancer of the adrenal medulla or to assess for the cause of hypertension.

SPECIMEN: Urine (25 mL) from a timed specimen collected in a clean amber plastic collection container with 6N hydrochloride as a preservative.

NORMAL FINDINGS: (Method: High-pressure liquid chromatography)

Age	Conventional Units	SI Units
<i>Normetanephrines (Conventional Units × 5.07)</i>		
3 mo–4 yr	54–249 mcg/24 hr	274–1,262 micromol/day
5–9 yr	31–398 mcg/24 hr	157–2,018 micromol/day
10–17 yr	67–531 mcg/24 hr	340–2,692 micromol/day
18–39 yr	35–482 mcg/24 hr	177–2,444 micromol/day
Greater than 40 yr	88–676 mcg/24 hr	446–3,427 micromol/day
<i>Metanephrines, Total (Conventional Units × 5.07)</i>		
3 mo–4 yr	79–345 mcg/24 hr	401–1,749 micromol/day
5–9 yr	49–409 mcg/24 hr	248–2,074 micromol/day
10–17 yr	107–741 mcg/24 hr	543–3,757 micromol/day
18–39 yr	94–695 mcg/24 hr	477–3,524 micromol/day
40–49 yr	182–739 mcg/24 hr	923–3,747 micromol/day
Greater than 50 yr	224–832 mcg/24 hr	1,136–4,218 micromol/day

DESCRIPTION: Metanephrines are the inactive metabolites of epinephrine and norepinephrine. Metanephrines are either excreted or further metabolized into vanillylmandelic acid. Release of metanephrines in the urine is indicative of disorders associated with excessive catecholamine production, particularly pheochromocytoma. Vanillylmandelic acid and catecholamines are normally measured with urinary metanephrines. Creatinine is usually measured simultaneously to

ensure adequate collection and to calculate an excretion ratio of metabolite to creatinine.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of suspected pheochromocytoma
- Assist in identifying the cause of hypertension
- Verify suspected tumors associated with excessive catecholamine secretion

POTENTIAL DIAGNOSIS**Increased in**

- Ganglioneuroma
- Neuroblastoma
- Pheochromocytoma
- Severe stress

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase metanephrine levels include monoamine oxidase inhibitors and prochlorperazine.
- Methylglucamine in x-ray contrast medium may cause false-negative results.
- All urine voided for the timed collection period must be included in the collection or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing adrenal gland health and hypertension.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan,

or toilet-mounted collection device.

Address concerns about pain and explain that there should be no discomfort during the procedure.

- ▶ Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- ▶ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.
- ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, thus invalidating the test.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to avoid excessive exercise and stress during the 24-hr collection of urine.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with activity restrictions during the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

Timed Specimen

- ▶ Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- ▶ Begin the test between 6 and 8 a.m. if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- ▶ Include on the collection container's label the amount of urine and test start and stop times.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual activity, as directed by the HCP.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography adrenal, cancer antigens, catecholamines, CT renal, HVA, renin, and VMA.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Methemoglobin

SYNONYM/ACRONYM: Hemoglobin, hemoglobin M, MetHb, Hgb M.

COMMON USE: To assess for cyanosis and hypoxemia associated with polycythemia, pathologies affecting hemoglobin, and potential inhaled drug toxicity.

SPECIMEN: Whole blood (1 mL) collected in green-top (heparin) tube. Specimen should be transported tightly capped and in an ice slurry.

NORMAL FINDINGS: (Method: Spectrophotometry)

Conventional Units	SI Units (Conventional Units × 155)
0.06–0.24 g/dL	9.3–37.2 micromol/L

Percentage of total hemoglobin = 0.41–1.15%.

Note: The conversion factor of ×155 is based on the molecular weight of hemoglobin of 64,500 daltons (d), or 64.5 kd.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS**Increased in**

- Acquired methemoglobinemia (drugs, tobacco smoking, or ionizing radiation)
- Carbon monoxide poisoning (*carbon monoxide is a form of deoxygenated hemoglobin*)
- Hereditary methemoglobinemia (*evidenced by a deficiency of NADH-methemoglobin reductase or related to the presence of a hemoglobinopathy*)

Decreased in: N/A

CRITICAL FINDINGS 

Cyanosis can occur at levels greater than 10%.

Dizziness, fatigue, headache, and tachycardia can occur at levels greater than 30%.

Signs of central nervous system depression can occur at levels greater than 45%.

Death may occur at levels greater than 70%.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional

nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Possible interventions include airway protection, administration of oxygen, monitoring neurological status every hour, continuous pulse oximetry, hyperbaric oxygen therapy, and exchange transfusion. Administration of activated charcoal or gastric lavage may be effective if performed soon after the toxic agent is ingested. Emesis should never be induced in patients with no gag reflex because of the risk of aspiration. Methylene blue may be used to reverse the process of methemoglobin formation, but it should be used cautiously when methemoglobin levels are greater than 30%. Use of methylene blue is contraindicated in the presence of glucose-6-phosphate dehydrogenase deficiency.

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Microalbumin

SYNONYM/ACRONYM: Albumin, urine.

COMMON USE: To assist in the identification and management of early diabetes in order to avoid or delay onset of diabetic associated renal disease.

SPECIMEN: Urine (10 mL) from a random or timed specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Immunoassay)

Test	Conventional Units	SI Units (Conventional Units x .001)
Random microalbumin	Less than 30 mcg albumin/mg creatinine	Less than 0.03 mg albumin/g creatinine
24-hr microalbumin		
Normal	Less than 30 mg/g creatinine/24 hr	Less than 0.03 mg/g creatinine/24 hr
Microalbuminuria	30–299 mg/g creatinine/24 hr	0.03–0.3 mg/g creatinine/24 hr
Clinical albuminuria	300 mg or greater/g creatinine/24 hr	0.3 mg or greater/g creatinine/24 hr

Simultaneous measurement of urine creatinine or creatinine clearance may be requested. Normal ratio of microalbumin to creatinine is less than 30:1 or 0–30 mg microalbumin/g creatinine/24 hr. The American Diabetes Association recommends annual measurement of serum creatinine and eGFR regardless of microalbumin levels; numerous factors such as hydration status, the presence of an infection, or significant hyperglycemia can produce falsely increased or decreased microalbumin levels. Therefore, the ADA recommends classification of microalbuminuria after two of three 24-hr samples collected in a 3–6 month period reflect abnormal results. The National Kidney Foundation defines microalbuminuria as equal to or greater than 30 mg/g creatinine/24 hr based on eGFR measurements.

DESCRIPTION: The term *microalbumin* describes concentrations of albumin in urine that are greater than normal but undetectable by dipstick or traditional spectrophotometry methods. Microalbuminuria precedes the nephropathy associated with diabetes and is often elevated years before creatinine clearance shows abnormal values. Studies have shown that the median duration from onset of microalbuminuria to development of nephropathy is 5 to 7 yr.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate renal disease
- Screen diabetic patients for early signs of nephropathy

POTENTIAL DIAGNOSIS

Increased in
Conditions resulting in increased renal excretion or loss of protein.

- Cardiomyopathy
- Diabetic nephropathy

- Exercise
- Hypertension (uncontrolled)
- Pre-eclampsia
- Renal disease
- Urinary tract infections

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may decrease microalbumin levels include captopril,

dipyridamole, enalapril, furosemide, indapamide, perindopril, quinapril, ramipril, tolrestat, and simvastatin (Triflusal).

- All urine voided for the timed collection period must be included in the collection, or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Blood glucose (<i>Related to sedentary lifestyle, circulating insulin deficiency secondary to pancreatic insufficiency; excessive dietary intake; insulin resistance; pregnancy</i>)	Excess: Fatigue; mild dehydration; elevated blood glucose; weight loss; weakness; polyuria; polydipsia; polyphagia; blurred vision; headache; paresthesia; poor skin turgor; dry mouth; nausea; vomiting; abdominal pain; Kussmaul respirations. Deficit: tremor, sweating, decreased concentration; diaphoresis; elevated blood pressure; palpitations; headache; hunger; restlessness; lethargy; altered mental status; combativeness; altered speech; altered coordination	Check blood glucose before meals and at bedtime; administer prescribed insulin or oral agents; educate and encourage the patient to participate in glucose self-check and record results; assess readiness to learn and barriers to learning; collaborate with the health-care provider (HCP) and dietician to support medical nutritional therapy; work with dietician to assist the patient to select appropriate cultural foods; develop a plan of exercise commensurate with the patient's physical abilities; discuss lifestyle alterations necessary to support positive health management secondary to disease process; teach good hygiene and infection prevention; monitor laboratory studies that may be impacted by altered

Problem	Signs & Symptoms	Interventions
Nutrition <i>(Related to excessive dietary intake more than body requirements, insulin deficiency, stress; anxiety; depression; cultural lifestyle; unhealthy food sources; financial restrictions)</i>	Increased thirst, increased urination, weight loss; fatigue; elevated blood glucose levels; inadequate glucose management; increased hunger	glucose and trend results (HGB A1C; BUN; Cr; electrolytes; arterial pH; magnesium; urine ketones; urine microalbumin; WBC; amylase; HGB/HCT; WBC; C-reactive protein; liver enzymes); facilitate oral hydration; correlate blood glucose with other laboratory values and medical condition(s); address the psychosocial aspects of the disease; monitor serum insulin levels Monitor blood glucose results, refer to dietician for evaluation, administer insulin or oral agent; assess the cultural aspects of diet selection; correlate dietary intake with blood glucose and monitor trends; collaborate with a dietician to develop a cultural- and age-appropriate diet plan; correlate nutritional intake and exercise; ensure that the patient understands the relationship between caloric intake and medication (insulin, oral agent); provide social services, dietary referrals if necessary
Renal impairment <i>(Related to elevated blood glucose levels over time; decreased renal perfusion; prolonged hypotension; heart disease)</i>	Altered fluid, electrolyte, and acid base balance; decreasing urinary output; elevated blood glucose	Review and trend diagnostic tests (BUN, Cr, urine osmolality, creatinine clearance, microalbumin, blood glucose); teach accurate self-administration of medication to control blood pressure and blood glucose; teach accurate monitoring of blood

<p><i>with altered cardiac output)</i></p> <p>Health management <i>(Related to complexity of health-care system; complexity of therapeutic management; altered metabolic process resulting in increased or decreased potassium; knowledge deficit; conflicted decision making; cultural family health patterns; barriers to healthy decisions; mistrust of HCP)</i></p>	<p>Health choices are ineffective in making a difference on outcomes; increasing symptoms of illness; verbalizes that therapeutic regime is too difficult; patient and family do not support HCP's suggestions for health improvement; refusal to follow recommended therapeutic regime</p>	<p>glucose; ensure compliance with recommended dietary and exercise regimes; monitor and trend glomerular filtration rate</p> <p>Assess effort to follow recommended regime; assess family or cultural factors that impact the success of the therapeutic regime; assess the patient's self-assessment of his or her health status; include the patient and family in designing the plan of care; tailor the plan of care to the patient's lifestyle; collaborate with the patient and family to develop a system of managing own health; focus on behaviors that will make the biggest positive impact on improved health</p>

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating for early kidney disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- ▶ Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- ▶ Instruct the patient to void all urine into the collection device and then to

pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to avoid excessive exercise and stress during the 24-hr collection of urine.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with activity restrictions during the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

Random Specimen (Collect in Early Morning)

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling Catheter

- ▶ Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed Specimen

- ▶ Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
 - ▶ Begin the test between 6 and 8 a.m. if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
 - ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
 - ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
 - ▶ Include on the collection container's label the amount of urine and test start and stop times.
- General**
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Increased levels of microalbumin may be associated with diabetes. There is no “diabetic diet”; however, many meal-planning approaches with nutritional goals are endorsed by the American Dietetic Association (ADA). Patients who adhere to dietary recommendations report a better general feeling of health, better weight management, greater control of glucose and lipid values, and improved use of insulin. Instruct the patient, as appropriate, in nutritional management of diabetes. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The nutritional needs of each diabetic patient need to be determined individually (especially during pregnancy) with the appropriate health-care professionals, particularly professionals trained in nutrition.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independence and fear of shortened life expectancy.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. The ADA recommends A_{1c} testing four times a year for patients whose treatment plan has changed or who are not meeting treatment goals and twice a year for patients who are meeting treatment goals and have stable, good glycemic control. Testing for microalbumin is recommended annually upon diagnosis of type 2 diabetes and five years after the diagnosis of type 1 diabetes. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to resume usual activity, as directed by the HCP.
- ▶ Instruct the patient and caregiver to report signs and symptoms of hypoglycemia or hyperglycemia.
- ▶ Discuss the implications of abnormal test results on the patient's lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Emphasize, if indicated, that good glycemic control delays the onset and slows the progression of diabetic retinopathy, nephropathy, and neuropathy.
- ▶ Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American Diabetes Association (www.diabetes.org) or the AHA (www.americanheart.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient that diabetes that is not controlled can cause multiple health issues including renal failure resulting in necessary dialysis to support life.

Expected Patient Outcomes:**Knowledge**

- ▶ States understanding that a urine test can assess for early renal failure associated with diabetes

- States understanding that renal failure can lead to death

Skills

- Demonstrates proficiency in the ability to perform a self-check glucose accurately
- Demonstrates proficiency in the ability to perform insulin self-administration correctly or to take oral agent

Attitude

- Complies with the HCP-recommended therapeutic regime to manage diabetes
- Complies with the recommendation to attend support groups to learn how to manage disease process

RELATED MONOGRAPHS:

- Related tests include A/G ratio, angiography renal, blood pool imaging, BUN, CBC, cortisol, creatinine, creatinine clearance, culture urine, cystometry, cystoscopy, cytology urine, echocardiography, echocardiography transesophageal, EPO, fluorescein angiography, fundus photography, glucose, GTT, glycosylated hemoglobin, gonioscopy, Holter monitor, insulin, insulin antibodies, magnesium, protein total and fractions, renogram, UA, visual fields test, and voiding cystourethrography.
- Refer to the Endocrine and Genitourinary systems tables at the end of the book for related tests by body system.

Mumps Serology

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in diagnosing a present or past mumps infection.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Indirect immunofluorescence)

	IgM	Interpretation	IgG	Interpretation
Negative	0.89 index or less	No significant level of detectable antibody	Less than 5 IU/mL	No significant level of detectable antibody; indicative of nonimmunity
Indeterminate	0.9–1.0 index	Equivocal results; retest in 10–14 d	6–9 IU/mL	Equivocal results; retest in 10–14 d
Positive	1.1 index or greater	Antibody detected; indicative of recent immunization, current or recent infection	10 IU/mL or greater	Antibody detected; indicative of immunization, current or past infection

DESCRIPTION: Mumps serology is done to determine the presence of mumps antibody, indicating exposure to or active presence of mumps. Mumps, also known as *parotitis*, is an infectious viral disease of the parotid glands caused by a myxovirus that is transmitted by direct contact with or droplets spread from the saliva of an infected person. The incubation period averages 3 wk. Virus can be shed in saliva for 2 wk after infection and in urine for 2 wk after the onset of symptoms. Complications of infection include aseptic meningitis; encephalitis; and inflammation of the testes, ovaries, and pancreas. The presence of immunoglobulin M (IgM) antibodies indicates acute infection. The presence of immunoglobulin G (IgG) antibodies indicates current or past infection.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine resistance to or protection against the mumps virus by a positive reaction or susceptibility to mumps by a negative reaction
- Document immunity
- Evaluate mumps-like diseases and differentiate between these and actual mumps

POTENTIAL DIAGNOSIS

Past or current mumps infection.

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing a mumps infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex. Obtain a history of exposure.
- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in detectable levels of antibodies. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in

Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient in isolation precautions during the time of communicability or contagion.
- ▶ Emphasize that the patient must return to have a convalescent blood sample taken in 7 to 14 days.

- ▶ Inform the patient that the presence of mumps antibodies ensures lifelong immunity.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Provide information regarding vaccine-preventable diseases where indicated (e.g., mumps). Provide contact information, if desired, for the Centers for Disease Control and Prevention www.cdc.gov/vaccines/vpd-vac. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Myocardial Infarct Scan

M

SYNONYM/ACRONYM: PYP cardiac scan, infarct scan, pyrophosphate cardiac scan, acute myocardial infarction scan.

COMMON USE: To differentiate between new and old myocardial infarcts and evaluate myocardial perfusion.

AREA OF APPLICATION: Heart, chest/thorax.

CONTRAST: IV radioactive material, usually technetium-99m stannous pyrophosphate (PYP).

DESCRIPTION: Technetium-99m stannous pyrophosphate (PYP) scanning, also known as *myocardial infarct imaging*, reveals the presence of myocardial perfusion

and the extent of myocardial infarction (MI). This procedure can distinguish new from old infarcts when a patient has had abnormal electrocardiograms

(ECGs) and cardiac enzymes have returned to normal. PYP uptake by acutely infarcted tissue may be related to the influx of calcium through damaged cell membranes, which accompanies myocardial necrosis; that is, the radionuclide may be binding to calcium phosphates or to hydroxyapatite. The PYP in these damaged cells can be viewed as spots of increased radionuclide uptake that appear in 12 hr at the earliest.

PYP uptake usually takes place 24 to 72 hr after MI, and the radionuclide remains detectable for approximately 10 to 14 days after the MI. PYP uptake is proportional to the blood flow to the affected area; with large areas of necrosis, PYP uptake may be maximal around the periphery of a necrotic area, with little uptake being detectable in the poorly perfused center. Most of the PYP is concentrated in regions that have 20% to 40% of the normal blood flow.

Single-photon emission computed tomography (SPECT) can be used to visualize the heart from multiple angles and planes, enabling areas of MI to be viewed with greater accuracy and resolution. This technique removes overlying structures that may confuse interpretation of the results. With the availability of newer biomarkers such as troponin, myocardial infarct imaging has become less important in the diagnosis of acute MI.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of (or confirm and locate) acute MI when ECG and enzyme testing do not provide a diagnosis
- Aid in the diagnosis of perioperative MI
- Differentiate between a new and old infarction
- Evaluate possible reinfarction or extension of the infarct
- Obtain baseline information about infarction before cardiac surgery

POTENTIAL DIAGNOSIS

Normal findings in

- Normal coronary blood flow and tissue perfusion, with no PYP localization in the myocardium
- No uptake above background activity in the myocardium (*Note:* when PYP uptake is present, it is graded in relation to adjacent rib activity)

Abnormal findings in

- MI, indicated by increased PYP uptake in the myocardium

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Other nuclear scans done within the previous 24 to 48 hr.
- Conditions such as chest wall trauma, cardiac trauma, or recent cardioversion procedure.
- Other conditions that may interfere include:
 - Aneurysms

- Cardiac neoplasms
- Left ventricular aneurysm
- Metastasis
- Myocarditis
- Pericarditis
- Valvular and coronary artery calcifications

Other considerations

- Improper injection of the radionuclide may allow the tracer to seep deep into the muscle tissue, producing erroneous hot spots.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation over-exposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assess blood flow to the heart.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.

▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.

▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.

▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by an HCP specializing in this procedure, with support staff, and will take approximately 30 to 60 min. Inform the patient that the technologist will administer an IV injection of the radionuclide and that he or she will need to return 2 to 3 hr later for the scan.

▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.

▶ Instruct the patient to fast, restrict fluids, and refrain from smoking for 4 hr prior to the procedure. Instruct the patient to withhold medications for 24 hr before the procedure. Protocols may vary among facilities.

▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injecting radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; hematoma **related to blood leakage into the tissue following needle insertion**; infection **that might occur if bacteria from the skin surface is introduced at the puncture site**; or nerve injury **that might occur if the needle strikes a nerve**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary and medication restrictions and other pretesting preparations.
- ▶ Ensure that the patient has removed all external metallic objects prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to lie very still during the procedure

because movement will produce unclear images.

- ▶ Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- ▶ IV radionuclide is administered. The heart is scanned 2 to 4 hr after injection in various positions. In most circumstances, however, SPECT is done so that the heart can be viewed from multiple angles and planes.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume normal activity and diet as directed by the HCP.
- ▶ Unless contraindicated, advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Evaluate the patient's vital signs. Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by HCP. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right

shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.

- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ If the patient must return for additional imaging, advise the patient to rest in the interim and restrict diet to liquids before redistribution studies.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to flush the toilet immediately after each voiding following the procedure and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing coronary artery disease (CAD) or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the

American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

- Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
 - ▶ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
 - ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the

need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▶ Related tests include angiography abdominal, AST, BNP, blood pool imaging, chest x-ray, CT abdominal, CT

thoracic, CK and isoenzymes, culture viral, echocardiography, echocardiography transesophageal, ECG, MRA, MRI chest, myocardial perfusion scan, pericardial fluid analysis, and PET heart.

Myocardial Perfusion Heart Scan

SYNONYM/ACRONYM: Sestamibi scan, stress thallium, thallium scan.

COMMON USE: To assess cardiac blood flow to evaluate for and assist in diagnosing coronary artery disease and myocardial infarction.

AREA OF APPLICATION: Heart, chest/thorax.

CONTRAST: IV or oral radionuclide.

DESCRIPTION: Cardiac scanning is a nuclear medicine study that reveals clinical information about coronary blood flow, ventricular size, and cardiac function.

Thallium-201 chloride rest or stress studies are used to evaluate myocardial blood flow to assist in diagnosing or determining the risk for ischemic cardiac disease, coronary artery disease (CAD), and myocardial infarction (MI). This procedure is an alternative to angiography or cardiac catheterization in cases in which these procedures may pose a risk to the patient. Thallium-201 is a potassium analogue and is taken up by myocardial cells proportional to blood flow to the cell and cell viability. During stress studies, the radionuclide is injected at peak exercise, after which the patient continues to exercise for several

minutes. During exercise, areas of heart muscle supplied by normal arteries increase their blood supply, as well as the supply of thallium-201 delivery to the heart muscle, to a greater extent than regions of the heart muscle supplied by stenosed coronary arteries. This discrepancy in blood flow becomes apparent and quantifiable in subsequent imaging. Comparison of early stress images with images taken after 3 to 4 hr redistribution (delayed images) enables differentiation between normally perfused, healthy myocardium (which is normal at rest but ischemic on stress) and infarcted myocardium.

Technetium-99m agents such as sestamibi (2-methoxyisobutylisonitrile) are delivered similarly to thallium-201 during myocardial perfusion imaging, but they are

extracted to a lesser degree on the first pass through the heart and are taken up by the mitochondria. Over a short period, the radionuclide concentrates in the heart to the same degree as thallium-201. The advantage to technetium-99m agents is that immediate imaging is unnecessary because the radionuclide remains fixed to the heart muscle for several hours. The examination requires two separate injections, one for the rest portion and one for the stress portion of the procedure. These injections can take place on the same day or preferably over a 2-day period. Examination quality is improved if the patient is given a light, fatty meal after the radionuclide is injected to facilitate hepatobiliary clearance of the radioactivity.

If stress testing cannot be performed by exercising, dipyridamole (Persantine) or adenosine, a vasodilator, can be administered orally or IV. A coronary vasodilator is administered before the thallium-201 or other radionuclide, and the scanning procedure is then performed. Vasodilators increase blood flow in normal coronary arteries twofold to threefold without exercise, and they reveal perfusion defects when blood flow is compromised by vessel pathology. Vasodilator-mediated myocardial perfusion scanning is reserved for patients who are unable to participate in treadmill, bicycle, or hand-grip exercises for stress testing because of lung disease, neurological disorders (e.g., multiple sclerosis, spinal cord injury), morbid obesity, and orthopedic disorders (e.g., arthritis, limb amputation).

Single-photon emission computed tomography can be used to visualize the heart from multiple

angles and planes, enabling areas of MI to be viewed with greater accuracy and resolution. This technique removes overlying structures that may confuse interpretation of the results.

This procedure is contraindicated for

- ◆ Patients who have taken sildenafil (Viagra) within the previous 48 hr, ***because this test may require the use of nitrates (nitroglycerin) that can precipitate life-threatening low blood pressure.***
- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients with bleeding disorders.
- ◆ Patients with left ventricular hypertrophy, right and left bundle branch block, and hypokalemia, and patients receiving cardiotoxic therapy.
- ◆ Patients with anginal pain at rest or patients with severe atherosclerotic coronary vessels ***in whom dipyridamole testing cannot be performed.***
- ◆ Patients with asthma, ***because chemical stress with vasodilators can cause bronchospasms.***

INDICATIONS

- Aid in the diagnosis of CAD or risk for CAD
- Determine rest defects and reperfusion with delayed imaging in unstable angina
- Evaluate the extent of CAD and determine cardiac function
- Assess the function of collateral coronary arteries

- Evaluate bypass graft patency and general cardiac status after surgery
- Evaluate the site of an old MI to determine obstruction to cardiac muscle perfusion
- Evaluate the effectiveness of medication regimen and balloon angioplasty procedure on narrow coronary arteries

POTENTIAL DIAGNOSIS

Normal findings in

- Normal wall motion, coronary blood flow, tissue perfusion, and ventricular size and function

Abnormal findings in

- Abnormal stress and resting images, indicating previous MI
- Abnormal stress images with normal resting images, indicating transient ischemia
- Cardiac hypertrophy, indicated by increased radionuclide uptake in the myocardium
- Enlarged left ventricle
- Heart chamber disorder
- Ventricular septal defects

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Medications such as digitalis and quinidine, which can alter cardiac contractility, and nitrates, which can affect cardiac performance.
- Single-vessel disease, which can produce false-negative thallium-201 scanning results.
- Conditions such as chest wall or cardiac trauma, angina that is difficult to control, significant cardiac arrhythmias, and recent cardioversion procedure.

- Suboptimal cardiac stress or patient exhaustion preventing maximum heart rate testing.
- Excessive eating or exercising between initial and redistribution imaging 4 hr later, which produces false-positive results.
- Improper adjustment of the radiological equipment to accommodate obese or thin patients, which can cause overexposure or underexposure and a poor-quality study.
- Patients who are very obese or who may exceed the weight limit for the equipment.
- Incorrect positioning of the patient, which may produce poor visualization of the area to be examined.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
 - Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
 - Inaccurate timing for imaging after radionuclide injection can affect the results.
 - Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.
- Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to reveal their level of exposure to radiation.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing blood flow to the heart.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's cardiovascular system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain and explain that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in a special department, usually in a radiology or vascular suite, by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as

- normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct the patient to wear walking shoes (if treadmill exercise testing is to be performed), and emphasize the importance of reporting fatigue, pain, or shortness of breath.
- ▶ Instruct the patient to remove dentures, jewelry, and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to fast for 4 hr, refrain from smoking for 4 to 6 hr, and withhold medications for 24 hr before the test. Instruct the patient to avoid taking anti-coagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

INTRATEST:

Potential Complications:

- Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injecting radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners;** hematoma **related to blood leakage into the tissue following needle insertion;** infection **that might occur if bacteria from the skin surface is introduced at the puncture site;** or nerve injury **that might occur if the needle strikes a nerve.**
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

- ▶ Ensure that the patient has complied with dietary, tobacco, and medication restrictions and other pretesting preparations for 4 to 6 hr prior to the procedure.
 - ▶ Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Have emergency equipment readily available.
 - ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
 - ▶ Instruct the patient to void prior to the procedure and change into the gown, robe, and foot coverings provided.
 - ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
 - ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
 - ▶ Instruct the patient to cooperate fully and to follow directions.
 - ▶ Place electrocardiographic (ECG) electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias. Monitor the patient's blood pressure throughout the procedure by using an automated blood pressure machine.
 - ▶ Assist the patient onto the treadmill or bicycle ergometer and ask the patient to exercise to a calculated 80% to 85% of the maximum heart rate, as determined by the protocol selected.
 - ▶ Wear gloves during the radionuclide injection and while handling the patient's urine.
 - ▶ Thallium-201 is injected 60 to 90 sec before exercise is terminated, and imaging is done immediately in the supine position and repeated in 4 hr.
 - ▶ Patients who cannot exercise are given dipyridamole 4 min before thallium-201 is injected.
 - ▶ Inform the patient that movement during the resting procedure affects the results and makes interpretation difficult.
 - ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, or bronchospasm).
 - ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
 - ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
 - ▶ The results are recorded on film or in a computerized system for recall and postprocedure interpretation by the appropriate HCP.
- POST-TEST:**
- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
 - ▶ Instruct the patient to resume normal diet and activity, as directed by the HCP.
 - ▶ Unless contraindicated, advise patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.
 - ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
 - ▶ Evaluate the patient's vital signs. Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by HCP. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
 - ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
 - ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
 - ▶ Instruct the patient in the care and assessment of the injection site.
 - ▶ If the patient must return for additional imaging, advise the patient to rest in

the interim and restrict diet to liquids before redistribution studies.

- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to flush the toilet immediately after each voiding following the procedure and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.

▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline

emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

▶ **Social and Cultural Considerations:**

- ▶ Numerous studies point to the prevalence of excess body weight in American children and adolescents. Experts estimate that obesity is present in 25% of the population ages 6 to 11 yr. The medical, social, and emotional consequences of excess body weight are significant. Special attention should be given to instructing the child and caregiver regarding health risks and weight-control education.
- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient’s lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the American Heart Association (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).
- ▶ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antiarrhythmic drugs, apolipoprotein A and B,

AST, atrial natriuretic peptide, BNP, calcium, cholesterol (total, HDL, LDL), CT cardiac scoring, CRP, CK and isoenzymes, echocardiography, echocardiography transesophageal, ECG, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and

isos, lipoprotein electrophoresis, magnesium, MRI chest, MI infarct scan, myoglobin, PET heart, potassium, triglycerides, and troponin.

Refer to the Cardiovascular System table at the end of the book for related tests by body system.

Myoglobin

SYNONYM/ACRONYM: MB.

COMMON USE: A general assessment of damage to skeletal or cardiac muscle from trauma or inflammation.

SPECIMEN: Serum (1 mL) collected in a red- or red/gray-top tube.

NORMAL FINDINGS: (Method: Electrochemiluminescent immunoassay)

	Conventional Units	SI Units (Conventional Units × 0.0571)
Male	28–72 ng/mL	1.6–4.1 nmol/L
Female	25–58 ng/mL	1.4–3.3 nmol/L

Values are higher in males.

DESCRIPTION: Myoglobin is an oxygen-binding muscle protein normally found in skeletal and cardiac muscle. It is released into the bloodstream after muscle damage

from ischemia, trauma, or inflammation. Although myoglobin testing is more sensitive than creatinine kinase and isoenzymes, it does not indicate the specific site involved.

Timing for Appearance and Resolution of Serum/Plasma Cardiac Markers in Acute Myocardial Infarction

Cardiac Marker	Appearance (Hours)	Peak (Hours)	Resolution (Days)
AST	6–8	24–48	3–4
CK (total)	4–6	24	2–3
CK-MB	4–6	15–20	2–3
LDH	12	24–48	10–14
Myoglobin	1–3	4–12	1
Troponin I	2–6	15–20	5–7

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in predicting a flare-up of polymyositis
- Estimate damage from skeletal muscle injury or myocardial infarction (MI)

POTENTIAL DIAGNOSIS

Increased in

Conditions that cause muscle damage; damaged muscle cells release myoglobin into circulation.

- Cardiac surgery
- Cocaine use (*rhabdomyolysis is a complication of cocaine use or overdose*)

- Exercise
- Malignant hyperthermia
- MI
- Progressive muscular dystrophy
- Renal failure
- Rhabdomyolysis
- Shock
- Thrombolytic therapy

Decreased in

- Myasthenia gravis
- Presence of antibodies to myoglobin, as seen in patients with polymyositis
- Rheumatoid arthritis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Mobility (<i>Related to progressive muscle wasting</i>)	Weakness; waddling gait; lordosis; large calf muscles; difficulty moving from lying to sitting position; clumsiness; falling; difficulty running	Encourage use of appropriate assistive devices including braces and wheelchairs; encourage active and passive range-of-motion exercises; promote independence; provide physical therapy as prescribed by the health-care provider
Family process (<i>Related to altered role performance secondary to disease progression</i>)	Inability to perform in supportive family role; alteration in family finances; change in communication patterns; change in the assignment of family tasks and the performance of those tasks; alterations in intimacy	Encourage family counseling; facilitate opportunities for the patient and family to express their feelings; assess patient's and family's perception of the problems; evaluate patient and family weaknesses, strengths, and coping strategies; help the family and patient break down concerns into manageable parts

(table continues on page 1162)

Problem	Signs & Symptoms	Interventions
Self-esteem (<i>Related to altered genetic alterations associated with muscular dystrophy</i>)	Compromised IQ; learning disability; easily distracted	Encourage tasks that can be easily completed to decrease frustration and increase self-esteem; prevent deformities with interventions that have been ordered by the physician

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing cardiac or skeletal muscle damage.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Abnormal myoglobin levels may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing coronary artery disease (CAD) or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical

activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

- ▶ Recognize anxiety related to test results, and be supportive of fear of shortened life expectancy.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Patient Education:

- ▶ Discuss the implications of abnormal test results on the patient’s lifestyle.
- ▶ Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Educate the patient regarding access to counseling services.
- ▶ Provide contact information, if desired, for the AHA (www.americanheart.org) or the NHLBI (www.nhlbi.nih.gov).

- ▶ Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Teach the patient and family that this is an inherited genetic disease.
- ▶ Teach the family how to communicate concerns appropriately.

Expected Patient Outcomes:

Knowledge

- ▶ Acquires understanding that muscular dystrophy is not curable
- ▶ States that addressing disease concerns in small segments can assist in finding solutions

Skills

- ▶ Identifies resources available for supportive care when needed
- ▶ Demonstrates proficient use of assistive devices

Attitude

- ▶ Complies with the HCP recommendation for family genetic testing to identify those female members at risk for passing the disease to male children
- ▶ Complies with the recommendation to use assistive devices to support mobility and decrease fall injury risk

RELATED MONOGRAPHS:

- ▶ Related tests include antiarrhythmic drugs, apolipoprotein A and B, AST, ANP, blood gases, BNP, calcium, cholesterol (total, HDL, and LDL), CRP, CK and isoenzymes, CT cardiac scoring, echocardiography, echocardiography transesophageal, ECG, exercise stress test, glucose, glycated hemoglobin, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI infarct scan, myoglobin, pericardial fluid analysis, PET heart, potassium, triglycerides, and troponin.
- ▶ Refer to the Cardiovascular and Musculoskeletal systems tables at the end of the book for related tests by body system.

Nerve Fiber Analysis

SYNONYM/ACRONYM: NEA.

COMMON USE: To assist in measuring the thickness of the retinal nerve fiber layer, to assist in diagnosing diseases of the eye such as glaucoma.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Normal findings in

- Normal nerve fiber layer thickness

Abnormal findings in

- Glaucoma or suspicion of glaucoma
- Ocular hypertension
- Optic nerve disease

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Newborn Screening

SYNONYM/ACRONYM: NBS, newborn metabolic screening, tests for inborn errors of metabolism.

COMMON USE: To evaluate newborns for congenital abnormalities, which may include hearing loss; identification of hemoglobin variants such as thalassemias and sickle cell anemia; presence of antibodies that would indicate a HIV infection; or metabolic disorders such as homocystinuria, maple syrup urine disease (MSUD), phenylketonuria (PKU), tyrosinuria, and unexplained mental retardation.

AREA OF APPLICATION: Ears for hearing tests.

SPECIMEN: Whole blood for metabolic tests.

NORMAL FINDINGS: (Method: Thyroxine, TSH, and HIV—immunoassay; amino acids—tandem mass spectrometry; hemoglobin variants—electrophoresis)

Hearing Test	
Age	Normal Findings
Neonates–3 days	Normal pure tone average of –10 to 15 dB

Thyroid-Stimulating Hormone (TSH)

Age	Conventional Units	SI Units (Conventional Units \times 1)
Neonates– 3 days	Less than 20 micro- international units/mL	Less than 20 milli-international units/L

Thyroxine, Total

Age	Conventional Units	SI Units (Conventional Units \times 17.1)
Neonates–30 days	5.4–22.6 mcg/dL	92–386 nmol/L

Hemoglobinopathies

Normal Hemoglobin Pattern

Blood spot amino acid analysis

Normal findings. Numerous amino acids are evaluated by blood spot testing, and values vary by method and laboratory. The testing laboratory should be consulted for corresponding reference ranges.

HIV antibodies

Negative

DESCRIPTION: Newborn screening is a process used to evaluate infants for disorders that are treatable but difficult to identify by direct observation of diagnosable symptoms. The testing is conducted shortly after birth and is mandated in all 50 states and U.S. territories through a collaborative effort between government agencies, local public health departments, hospitals, and parents. Testing is categorized as core tests and second-tier tests. The testing included in mandatory newborn screening programs varies among states and territories; testing of interest that is not included in the mandatory list can be requested by a health-care provider (HCP), as appropriate. Confirmatory testing is performed if abnormal findings are produced by screening methods. Properly collected blood spot cards contain sufficient sample to perform both screening and confirmatory testing. Confirmatory testing

varies depending on the initial screen and can include fatty acid oxidation probe tests on skin samples, enzyme uptake testing of skin or muscle tissue samples, enzyme assays of blood samples, DNA testing, gas chromatography/mass spectrometry, and tandem mass spectrometry. Testing for common genetically transferred conditions can be performed on either or both prospective parents by blood tests, skin tests, or DNA testing. DNA testing can also be performed on the fetus, in utero, through the collection of fetal cells by amniocentesis or chorionic villus sampling. Counseling and written, informed consent are recommended and sometimes required before genetic testing.

Every state and U.S. territory has a newborn screening program, which includes early hearing loss detection and intervention (EHDI). The goal of EHDI is to assure that permanent hearing loss is identified

before 3 months of age, appropriate and timely intervention services are provided before 6 months of age, families of infants with hearing loss receive culturally competent support, and tracking and data management systems for newborn hearing screens are linked with other relevant public health information systems. For more detailed information refer to the monograph titled “Audiometry Hearing Loss”.

The adrenal glands are responsible for production of the hormones cortisol, aldosterone, and male sex androgens. Most infants born with congenital adrenal hyperplasia (CAH) make too much of the androgen hormones and not enough cortisol or aldosterone. The complex feedback loops in the body call for the adrenal glands to increase production of cortisol and aldosterone, and as the adrenal glands work harder to increase production, they increase in size, resulting in hyperplasia. CAH is a group of conditions. Most frequently, lack of or dysfunction of an enzyme called 21-hydroxylase results in one of two types of CAH. The first is a salt-wasting condition in which insufficient levels of aldosterone causes too much salt and water to be lost in the urine. Newborns with this condition are poor feeders and appear lethargic or sleepy. Other symptoms include vomiting, diarrhea, and dehydration, which can lead to weight loss, low blood pressure, and decreased electrolytes. If untreated, these symptoms can result in metabolic acidosis and shock, which in CAH infants is called an *adrenal crisis*. Signs of an adrenal crisis include confusion, irritability, tachycardia, and coma. The second most common type of CAH is a condition in which having too much of the androgen hormones in

the blood causes female babies to develop masculinized or virilized genitals. High levels of androgens leads to precocious sexual development, well before the normal age of puberty, in both boys and girls.

Inadequate production of the thyroid hormone thyroxine can result in congenital hypothyroidism, which when untreated manifests in severely delayed physical and mental development. Inadequate production may be due to a defect such as a missing, misplaced, or malfunctioning thyroid gland. Inadequate production may also be due to the mother's thyroid condition or treatment during pregnancy or, less commonly encountered in developed nations, a maternal deficiency of iodine. Most newborns do not exhibit signs and symptoms of thyroxine deficiency during the first few weeks of life while they function on the hormone provided by their mother. As the maternal thyroxine is metabolized, some of the symptoms that ensue include coarse, swollen facial features; wide, short hands; respiratory problems; a hoarse-sounding cry; poor weight gain and small stature; delayed occurrence of developmental milestones such as sitting up, crawling, walking, and talking; goiter; anemia; bradycardia; myxedema (accumulation of fluid under the skin); and hearing loss. Children who remain untreated usually become mentally retarded and demonstrate physical disabilities; they may have an unsteady gait and lack coordination. Most demonstrate delays in development of speech, and some have behavioral problems.

Hemoglobin (Hgb) A is the main form of Hgb in the healthy adult. Hgb F is the main form of Hgb in the fetus, the remainder being composed of Hgb A₁ and A₂, Hgb S and C

result from abnormal amino acid substitutions during the formation of Hgb and are inherited hemoglobinopathies. Hgb S results from an amino acid substitution during Hgb synthesis whereby valine replaces glutamic acid. Hemoglobin C Harlem results from the substitution of lysine for glutamic acid. Hgb electrophoresis is a separation process used to identify normal and abnormal forms of Hgb. Electrophoresis and high-performance liquid chromatography as well as molecular genetics testing for mutations can also be used to identify abnormal forms of Hgb. Individuals with sickle cell disease have chronic anemia because the abnormal Hgb is unable to carry oxygen. The red blood cells of affected individuals are also abnormal in shape, resembling a crescent or sickle rather than the normal disk shape. This abnormality, combined with cell-wall rigidity, prevents the cells from passing through smaller blood vessels. Blockages in blood vessels result in hypoxia, damage, and pain. Individuals with the sickle cell trait do not have the clinical manifestations of the disease but may pass the disease on to children if the other parent has the trait (or the disease) as well.

Amino acids are required for the production of proteins, enzymes, coenzymes, hormones, nucleic acids used to form DNA, pigments such as hemoglobin, and neurotransmitters. Testing for specific amino acidopathies is generally performed on infants after an initial screening test with abnormal results. Certain congenital enzyme deficiencies interfere with normal amino acid metabolism and cause excessive accumulation of or deficiencies in amino acid levels. The major genetic disorders include phenylketonuria

(PKU), maple syrup urine disease (MSUD), and tyrosinuria. Enzyme disorders can also result in conditions of dysfunctional fatty acid or organic acid metabolism in which toxic substances accumulate in the body and, if untreated, can result in death. Infants with these conditions often appear normal and healthy at birth. Symptoms can appear soon after feeding begins or not until the first months of life, depending on the specific condition. Most of the signs and symptoms of amino acid disorders in infants include poor feeding, lethargy, vomiting, and irritability. Newborns with MSUD produce urine that smells like maple syrup or burned sugar. Accumulation of ammonia, a by-product of protein metabolism, and the corresponding amino acids, results in progressive liver damage, hepatomegaly, jaundice, and tendency to bruise and bleed. If untreated, there may be delays in growth, lack of coordination, permanent learning disabilities, and mental retardation. Early diagnosis and treatment of certain amino acidopathies can prevent mental retardation, reduced growth rates, and various unexplained symptoms.

Cystic fibrosis (CF) is a genetic disease that affects normal functioning of the exocrine glands, causing them to excrete large amounts of electrolytes. CF is characterized by abnormal exocrine secretions within the lungs, pancreas, small intestine, bile ducts, and skin. Some of the signs and symptoms that may be demonstrated by the newborn with CF include failure to thrive, salty sweat, chronic respiratory problems (constant coughing or wheezing, thick mucus, recurrent lung and sinus infections, nasal polyps), and chronic gastrointestinal problems (diarrhea, constipation,

pain, gas, and greasy, malodorous stools that are bulky and pale colored). Patients with CF have sweat electrolyte levels two to five times normal. Sweat test values, with family history and signs and symptoms, are required to establish a diagnosis of CF. Clinical presentation may include chronic problems of the gastrointestinal and/or respiratory system. CF is more common in Caucasians than in other populations. Testing of stool samples for decreased trypsin activity has been used as a screen for CF in infants and children, but this is a much less reliable method than the sweat test. Sweat conductivity is a screening method that estimates chloride levels. Sweat conductivity values greater than or equal to 50 mEq/L should be referred for quantitative analysis of sweat chloride. The sweat electrolyte test is still considered the gold standard diagnostic for CF.

Biotin is an important water-soluble vitamin/cofactor that aids in the metabolism of fats, carbohydrates, and proteins. A congenital enzyme deficiency of biotinidase prevents biotin released during normal cellular turnover or via digested dietary proteins from being properly recycled and absorbed, resulting in biotin deficiency. Signs and symptoms of biotin deficiency appear within the first few months and can result in hypotonia, poor coordination, respiratory problems, delays in development, seizures, behavioral disorders, and learning disabilities. Untreated, the deficiency can lead to loss of vision and hearing, ataxia, skin rashes, and hair loss.

Lactose, the main sugar in milk and milk products, is composed of galactose and glucose. Galactosemia occurs when there is a deficiency of the enzyme galactose-1-phosphate uridyl transferase, which is

responsible for the conversion of galactose into glucose. The inability of dietary galactose and lactose to be metabolized results in the accumulation of galactose-1-phosphate, which causes damage to the liver, central nervous system, and other body systems. Newborns with galactosemia usually have diarrhea and vomiting within a few days of drinking milk or formula containing lactose. Other early symptoms include poor suckling and feeding, failure to gain weight or grow in length, lethargy, and irritability. The accumulation of galactose-1-phosphate and ammonia is damaging to the liver, and symptoms likely to follow if untreated include hypoglycemia, seizures, coma, hepatomegaly, jaundice, bleeding, shock, and life-threatening bacteremia or septicemia. Early cataracts can occur in about 10% of children with galactosemia. Most untreated children eventually die of liver failure.

HIV is the etiological agent of AIDS and is transmitted through bodily secretions, especially by blood or sexual contact. The virus preferentially binds to the T4 helper lymphocytes and replicates within the cells. Current assays detect several viral proteins. Positive results should be confirmed by Western blot assay. This test is routinely recommended as part of a prenatal work-up and is required for evaluating donated blood units before release for transfusion. The Centers for Disease Control and Prevention (CDC) has structured its recommendations to increase identification of HIV-infected patients as early as possible; early identification increases treatment options, increases frequency of successful treatment, and can decrease further spread of disease.

Core Conditions Evaluated in Many States

Condition	Affected Component	Marker for Disease	Incidence	Potential Therapeutic Interventions	Outcomes of Therapeutic Interventions
Hearing loss	Damage to or malformations of the inner ear	Abnormal audiogram	1 in 3,000 births	Surgery, medications for infections, removal of substances blocking the ear canal, hearing aids	A shorter period of auditory deprivation has a positive impact on normal development.
Congenital adrenal hyperplasia (CAH) (classical)	Multiple types of CAH; majority have a deficiency of or nonfunctioning enzyme: 21-hydroxylase	17-hydroxyprogesterone (17-OHP)	1 in 25,000 births (75% have salt-wasting type; 25% have virilization type)	Oral cortisone administration, surgery for females with virilization	Patients who begin treatment soon after birth usually have normal growth and development.
Congenital hypothyroidism	Missing, misplaced, or malfunctioning thyroid gland resulting in insufficient thyroxine; insufficient thyroxine due to maternal thyroid	Thyroxine (total), thyroid-stimulating hormone	1 in 5,000 births	Administration of L-thyroxine	Patients who begin treatment soon after birth usually have normal growth and development.

Core Conditions Evaluated in Many States

Condition	Affected Component	Marker for Disease	Incidence	Potential Therapeutic Interventions	Outcomes of Therapeutic Interventions
• Homocystinuria	Deficiency of or nonfunctioning enzyme: cystathionine beta-synthase	Methionine	Less than 1 in 100,000 births (found more often in white people from the New England region of the United States and in people of Irish ancestry)	Consultation with dietician; diet low in methionine supplemented by special medical foods; administration of vitamin B ₆ , vitamin B ₁₂ , folic acid, betaine, and L-cystine	treatment can help prevent high ammonia levels. Accumulation of ammonia can cause brain damage, resulting in lifelong learning problems, mental retardation, or lack of coordination. Patients who begin treatment soon after birth and continue treatment throughout life usually have normal growth and development. Treatment may lower the chance for blood clots, heart disease, and stroke. Treatment

also lessens the chance of eye problems such as cataract or lens dislocation, which can often be corrected by surgery.

Patients who begin treatment soon after birth and continue treatment throughout life usually have normal growth and development. Untreated or delayed treatment results in brain damage and mental retardation.

Consultation with a dietician; diet low in branched-chain amino acids supplemented by special medical foods and formula, administration of thiamine; liver transplant

Less than 1 in 100,000 births (found more often in Mennonite people in certain parts of the United States: about 1 in 380 babies of Mennonite background is born with MSUD; also found more often in people of French-Canadian ancestry)

Leucine and isoleucine

Deficiency of or nonfunctioning enzyme group: branched-chain ketoacid dehydrogenase

• Maple syrup urine disease (MSUD)

(table continues on page 1174)

Core Conditions Evaluated in Many States

Condition	Affected Component	Marker for Disease	Incidence	Potential Therapeutic Interventions	Outcomes of Therapeutic Interventions
• Phenylketonuria	Deficiency of or nonfunctioning enzyme: phenylalanine hydroxylase (PAH)	Phenylalanine	1 in 10,000–15,000 births	Consultation with a dietician; diet low in phenylalanine supplemented by special medical foods and formula; administration of BH4 (tetrahydrobiopterin), which helps the PAH enzyme convert phenylalanine into tyrosine. Patients with this condition should avoid foods and vitamins containing the sugar substitute aspartame, which increases blood levels of phenylalanine	Patients who begin treatment soon after birth and continue treatment throughout life usually have normal growth and development. Some patients may experience delays in learning even after treatment, but without treatment or if treatment is delayed until after 6 mo of age, mental retardation usually results.
• Tyrosinemia type 1	Deficiency of or nonfunctioning enzyme: fumarylacetoacetase	Tyrosine	Less than 1 in 100,000 births (found more often in people of	Consultation with a dietician; diet low in tyrosine and phenylalanine	Patients who begin treatment soon after birth and continue treatment

French-Canadian
ancestry)

supplemented by special medical foods and formula; administration of nitisinone to prevent liver and kidney damage; liver transplant

throughout life usually have normal growth and development. Without treatment, liver and kidney damage will occur.

Inborn errors of fatty acid metabolism

• Carnitine uptake disorder

Deficiency of or nonfunctioning enzyme: carnitine transporter

Free and total carnitine
Less than 1 in 100,000 births

Consultation with a dietician; diet low in tyrosine and phenylalanine supplemented by special medical foods and formula

Patients who begin treatment soon after birth and continue treatment throughout life usually have normal growth and development. Without treatment, infants may incur brain damage resulting in permanent learning disabilities or mental retardation.

This procedure is contraindicated for: N/A

INDICATIONS

Hearing Tests

- Screen for hearing loss in infants to determine the need for a referral to an audiologist

Blood Spot testing

- Assist in the diagnosis of CAH
- Assist in the diagnosis of congenital hypothyroidism
- Assist in the diagnosis of abnormal hemoglobins as with Hgb C disease, sickle cell trait or sickle cell disease, and thalassemias, especially in patients with a family history positive for any the disorders
- Assist in identifying the cause of hemolytic anemia resulting from G-6-PD enzyme deficiency
- Detect congenital errors of amino acid, fatty acid, or organic acid metabolism
- Detect congenital errors responsible for urea cycle disorders
- Screen for multisystem disorders such as CF, biotinidase deficiency, or galactosemia
- Test for HIV antibodies in infants who have documented and significant exposure to other infected individuals

POTENTIAL DIAGNOSIS

Abnormal findings in

Hearing Test

- Abnormal audiogram (*related to congenital damage or malformations of the inner ear, infections, residual amniotic fluid or vernix in the ear canal*)

Endocrine Disorders

Increased in

- Congenital hypothyroidism (TSH) (*related to decrease in total*

thyroxine hormone levels, which activates the feedback loop to increase production of TSH)

- CAH (adrenocorticotrophic hormone [ACTH] and androgens) (*related to an autosomal recessive inherited disorder that results in missing or malfunctioning enzymes responsible for the production of cortisol and which may result in a salt-wasting condition or virilization of female genitalia*)

Decreased in

- Congenital hypothyroidism (total T₄) (*related to missing or malfunctioning thyroid gland resulting in absence or decrease in total thyroxine hormone levels*)
- CAH (21-hydroxylase) (*related to an autosomal recessive inherited disorder that results in missing or malfunctioning enzymes responsible for the production of cortisol and which may result in one of several conditions, including a salt-wasting condition or virilization of female genitalia*)
- CAH (cortisol) (*related to an autosomal recessive inherited disorder that results in missing or malfunctioning enzymes responsible for the production of cortisol and which may result in a salt-wasting condition or virilization of female genitalia*)
- CAH (aldosterone) (*related to an autosomal recessive inherited disorder that results in missing or malfunctioning enzymes responsible for the production of cortisol and which may result in a salt-wasting condition*)

Abnormal findings in

Hemoglobinopathies

- Hgb S: sickle cell trait or sickle cell anemia (most common variant in the United States; occurs with a frequency of about 8% among African

Americans) *(related to an autosomal recessive inherited disorder that results in a genetic variation in the β -chain of hemoglobin, causing a conformational change in the hemoglobin molecule and affecting the oxygen-binding properties of hemoglobin, which results in sickle-shaped red blood cells)*

- Hgb SC disease *(related to an autosomal recessive inherited disorder that results in the presence of an abnormal combination of Hgb S with Hgb C and presents a milder form of sickle cell anemia)*
- Hgb S/ β -thalassemias *(related to an autosomal recessive inherited disorder that results in the presence of abnormal hemoglobin S/ β -thalassemia, which combines the effects of thalassemia, a genetic disorder that results in decreased production of hemoglobin and sickle cell anemia, where sickled red blood cells lack the ability to combine effectively with oxygen)*

RBC Enzyme Defect

Decreased in

- G6PD deficiency *(usually related to an X-linked recessive inherited disorder that results in a deficiency of glucose-6-phosphate dehydrogenase, which causes a hemolytic anemia)*

Inborn Errors of Amino Acid Metabolism/Disorders of the Urea Cycle

- Aminoacidopathies *(usually related to an autosomal recessive inherited disorder that results in insufficient or nonfunctional enzyme levels; specific amino acids are implicated)*
- Disorders of the urea cycle; specifically argininemia, argininosuccinic

acidemia, citrullinemia, and hyperammonemia/hyperornithinemia/homocitrullinemia *(usually related to an autosomal recessive inherited disorder that results in insufficient or nonfunctional enzyme levels; specific amino acids are implicated)*

Inborn Errors of Organic Acid Metabolism

- Organic acid disorders *(usually related to an autosomal recessive inherited disorder that results in insufficient or nonfunctional enzyme levels; specific organic acids are implicated)*

Inborn Errors of Fatty Acid Metabolism

- Fatty acid oxidation disorders *(usually related to an autosomal recessive inherited disorder that results in insufficient or nonfunctional enzyme levels; specific fatty acids are implicated)*

Other Multisystem Diseases

- Biotinidase deficiency *(related to an autosomal recessive inherited disorder that results in deficiency of the enzyme biotinidase, which prevents absorption or recycling of the essential vitamin biotin)*
- Cystic fibrosis *(related to an autosomal recessive inherited disorder that results in insufficient or nonfunctional CF transmembrane conductance regulator protein, which results in poor transport of salts, especially sodium and chloride, and significantly impairs pulmonary and gastrointestinal function)*
- Galactosemia (classical) *(usually related to an autosomal recessive inherited disorder that results in insufficient or nonfunctional galactose-1-phosphate uridyl transferase enzyme levels)*

Infectious Diseases

Positive findings in

- HIV-1 or HIV-2 infection

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Specimens for newborn screening collected earlier than 24 h after the first feeding or collected from neonates receiving total parenteral nutrition may produce invalid results.
- Specimens for newborn screening that are improperly applied to the filter paper circles may produce invalid results.
- Touching blood spots after collection on the filter paper card may contaminate the sample and produce invalid results.
- Failure to let the filter paper sample dry may affect test results.
- Specimens for newborn screening collected after transfusion may produce invalid results.
- Nonreactive HIV test results occur during the acute stage of the disease, when the virus is present but antibodies have not sufficiently developed to be detected. It may take up to 6 mo for the test to become positive. During this stage, the test for HIV antigen may not confirm an HIV infection.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fear (<i>Related to diagnosed congenital anomaly of newborn; newborn disease; possibility infant death [HIV, sickle cell, etc.]</i>)	Expression of fear; expresses concern over caring for a disabled child; preoccupation with fear; increased tension; increased blood pressure; increased heart rate; vomiting; diarrhea; nausea; fatigue; weakness; insomnia; shortness of breath; increased respiratory rate; withdrawal; panic attacks	Provide access to social services; provide specific and culturally appropriate education; assist the patient and family to recognize effective coping strategies; assist the patient to acknowledge his or her fear; provide a safe environment to discuss fear; explore cultural influences that may enhance fear
Knowledge (<i>Related to diagnosis of childhood disability or disease; complexity of treatment; poor understating</i>)	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management, including management of disabled child; verbalizes inaccurate information; lack of	Identify patient's, family's, and significant others' concerns about child's diagnosed disease or disability; provide information and support group information on caring for a disabled child; provide information on treatment options related to disease or disability (hearing loss, sickle

Problem	Signs & Symptoms	Interventions
<i>of provided information; cultural or language barriers; anxiety; emotional disturbance; unfamiliar with medical management)</i>	follow through with directions	cell anemia, etc.); refer to online legitimate evidence-based sources for review; provide information related to genetic counseling
Nutrition (<i>Related to inability to metabolize galactose</i>)	Lethargy; weight loss; failure to thrive; jaundice; bleeding; developmental delays; speech delays; irritability; convulsions	Provide information for use of lactose-free formula, soy formula, or a protein-based hydrolysate formula; ensure strict avoidance of dairy products, organ meats, MSG, foods with sodium or calcium caseinate, any processed food that includes margarine as an ingredient, and any fermented soy sauce, once off of formula and on a regular diet
Infection (<i>Related to infant exposure in utero secondary to maternal HIV disease [maternal fetal transmission]; infected mother breastfeeding</i>)	Positive polymerase chain reaction testing in infants; delay in developmental milestones (walking, crawling, etc.) in toddlers; school-age children perform poorly; possible neurologic problems with ongoing disease	Administer ordered antiretroviral medication or prescribed treatment modality; discuss family support for treatment of the child and mother; assess infection in other family members and children; educate about the importance of adhering to treatment modalities; consider individual cultures and socioeconomic strategies to foster positive outcomes

PRETEST:**General**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Education regarding newborn screening should begin during the prenatal period and be reinforced at the time of preadmission

testing. Many birthing facilities and hospitals provide educational brochures to the parents. Physicians and physician delegates are responsible to inform parents of the newborn screening process before discharge. Inform the patient these procedures can assist in evaluating a number of congenital conditions, including hearing loss, thyroid function, adrenal gland

function, and other metabolic enzyme disorders. Evaluation may also include HIV antibody testing if not performed prenatally or if otherwise clinically indicated.

- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

Blood Tests

- ▶ Review the procedure with the parents or caregiver. Explain that blood specimens from neonates are collected by heel stick and applied to filter paper spots on the birth state's specific screening program card.

Hearing Test

- ▶ Review the procedure with the parents or caregiver. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the parents or caregiver that an audiologist or HCP trained in this procedure performs the test in a quiet room and that the test can take up 20 min to evaluate both ears. Explain that each ear is tested separately by using earphones and/or a device placed behind the ear to deliver sounds of varying intensities.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Most state regulations require screening specimens to be collected between 24 and 48 hr after birth to allow sufficient time after protein intake for abnormal metabolites to be detected, and preferably before blood product transfusion or physical transfer to another facility.

INTRATEST:

Potential Complications: N/A

Hearing Test

- ▶ Perform otoscopy examination to ensure that the external ear canal is free from any obstruction (see monograph titled "Otoscopy").
- ▶ Test for closure of the canal from the pressure of the earphones by compressing the tragus. Tendency for the canal to close (often the case in children and elderly patients) can be corrected by the careful insertion of a small, stiff plastic tube into the anterior canal.
- ▶ Start the test by providing a trial tone of 15 to 20 dB above the expected threshold to the ear for 1 to 2 sec to familiarize the patient with the sounds. If no response is indicated, the level is increased until a response is obtained, and then it is raised in 10-dB increments or until the audiometer's limit is reached for the test frequency. The test results are plotted on a graph called an audiogram using symbols that indicate the ear tested and responses using earphones (air conduction) or oscillator (bone conduction).

Air Conduction

- ▶ In the air conduction test, the tone is delivered to an infant through insert earphones or ear muffins, and the auditory response is measured through electrodes placed on the infant's scalp. Air conduction is tested first by starting at 1,000 Hz and gradually decreasing the intensity 10 dB at a time until there is no response, indicating that the tone is no longer heard. The intensity is then increased 5 dB at a time until the tone is heard again. This is repeated until the same response is achieved at a 50% response rate at the same hertz level. The threshold is derived from the lowest decibel level at which the patient correctly responds to three out of six trials to a tone at that hertz level. The test is continued for each ear with tones delivered at 1,000 Hz, 2,000 Hz, 4,000 Hz, and 8,000 Hz, and then again at 1,000 Hz, 500 Hz, and 250 Hz to determine a second threshold. Results are recorded on a graph

called an audiogram. Averaging the air conduction thresholds at the 500-Hz, 1,000-Hz, and 2,000-Hz levels reveals the degree of hearing loss and is called the pure tone average (PTA).

Bone Conduction

- ▶ Bone conduction testing is performed in a similar manner to air conduction testing; a vibrator placed on the skull is used to deliver tones to an infant instead of earphones as in the air conduction test. The raised and lowered tones are delivered as in air conduction using 250 Hz, 500 Hz, 1,000 Hz, 2,000 Hz, and 4,000 Hz to determine the thresholds. An analysis of thresholds for air and bone conduction tones is done to determine the type of hearing loss (conductive, sensorineural, or mixed).

Otoacoustic Emissions

- ▶ In otoacoustic testing, microphones are placed in the infant's ears. Nearby sounds should echo in the ear canal and be detected by the microphones if the infant's hearing is normal.

Filter Paper Test

- ▶ Obtain kit and cleanse heel with anti-septic. Observe standard precautions, and follow the general guidelines in Appendix A. Use gauze to dry the stick area completely. Perform heel stick, gently squeeze infant's heel, and touch filter paper to the puncture site. When collecting samples for newborn screening, it is important to apply each blood drop to the correct side of the filter paper card and fill each circle with a single application of blood. Overfilling or underfilling the circles will cause the specimen card to be rejected by the testing facility. Additional information is required on newborn screening cards and may vary by state. Newborn screening cards should be allowed to air dry for several hours on a level, non-absorbent, unenclosed area. If multiple patients are tested, do not stack cards. State regulations usually require the specimen cards to be submitted within 24 hr of collection. Observe/assess puncture site for bleeding or hematoma formation, and secure gauze with adhesive bandage.

POST-TEST:

- ▶ Inform the parent or caregiver that a report of the results will be made available to the requesting HCP, who will discuss the results with the parents or caregiver.
- ▶ **Nutritional Considerations:** Instruct the parents or caregiver in special dietary modifications to treat deficiency, and refer parents or caregiver to a qualified nutritionist, as appropriate. Amino acids are classified as essential (i.e., must be present simultaneously in sufficient quantities), conditionally or acquired essential (i.e., under certain stressful conditions, they become essential), and nonessential (i.e., can be produced by the body, when needed, if diet does not provide them). Essential amino acids include lysine, threonine, histidine, isoleucine, methionine, phenylalanine, tryptophan, and valine. Conditionally essential amino acids include cysteine, tyrosine, arginine, citrulline, taurine, and carnitine. Nonessential amino acids include alanine, glutamic acid, aspartic acid, glycine, serine, proline, glutamine, and asparagine. A high intake of specific amino acids can cause other amino acids to become essential.
- ▶ **Social and Cultural Considerations:** Recognize anxiety related to test results, and be supportive of parents' or caregiver's perceived loss of impaired activity or independence related to hearing loss or physical limitations and their fear of shortened life expectancy for the newborn. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the parents or caregiver regarding access to genetic or other counseling services. Provide contact information, if desired, for the March of Dimes (www.marchofdimes.com), the National Library of Medicine (www.nlm.nih.gov/medlineplus/newbornscreening.html), general information (newbornscreening.info/Parents/facts.html), or the state department of health newborn screening program. There are numerous support groups and informational Web sites for specific conditions, including

the National Center for Hearing Assessment and Management (www.infanthearing.org), the American Speech-Language-Hearing Association (www.asha.org), ABLEDATA (for assistive technology; sponsored by the National Institute on Disability and Rehabilitation Research [www.abledata.com]), the Sickle Cell Disease Association of America (www.sicklecelldisease.org), the Fatty Oxidation Disorders (FOD) Family Support Group (www.fodsupport.org), the Organic Acidemia Association (www.oaanews.org), the United Mitochondrial Disease Foundation (www.umdf.org), the Cystic Fibrosis Foundation (www.cff.org), and, for AIDS information, the National Institutes of Health (www.aidsinfo.nih.gov) and the CDC (www.cdc.gov).

▸ **Social and Cultural Considerations:** Inform parents or caregiver that positive neonatal HIV findings must be reported to local health department officials.

▸ **Social and Cultural Considerations:** Offer support, as appropriate, to parents who may be the victims of rape or sexual assault. Educate the parents regarding access to counseling services. Provide a nonjudgmental, nonthreatening atmosphere for a discussion during which risks of sexually transmitted diseases to the newborn are explained. It is also important to discuss problems the parents may experience (e.g., guilt, depression, anger).

▸ Depending on the results of these procedures, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- Answer any questions or address any concerns voiced by the parents, family, or caregiver.
- Provide information regarding vaccine-preventable diseases where indicated

(e.g., diphtheria, hepatitis B, measles, mumps, pertussis, polio, rotavirus, rubella, varicella). Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac).

Expected Patient Outcomes:

Knowledge

- The parent or caregiver states understanding of the importance of alternate language training (sign language) for an infant with hearing loss as soon as possible to enhance growth and development
- The parent or caregiver states understanding that failure to refrain from feeding the child foods that include galactose can result in severe disability and death

Skills

- The parent or caregiver demonstrates proficiency of accessing online resources as a source of ongoing information
- The parent or caregiver develops a diet free of dairy products to support the child's health maintenance

Attitude

- The parent or caregiver agrees to genetic counseling prior to having another child in identify risk of future disability in additional children
- The parent or caregiver agrees to adhere to HIV treatment plan for self and child

RELATED MONOGRAPHS:

- Related tests include amino acid screen, amniotic fluid analysis, audiometry hearing loss, biopsy chorionic villus, chloride sweat, chromosome analysis, CBC, evoked brain potential studies for hearing loss, glucose-6-phosphate dehydrogenase, hemoglobin electrophoresis, human immunodeficiency virus type 1 and type 2 antibodies, otoscopy, sickle cell screen, TSH, thyroxine total, and US thyroid.
- Refer to the Auditory, Endocrine, Genitourinary, Hematopoietic, Hepatobiliary, and Reproductive systems tables at the end of the book for related tests by body system.

Osmolality, Blood and Urine

SYNONYM/ACRONYM: Osmo.

COMMON USE: To assess fluid and electrolyte balance related to hydration, acid-base balance, and toxic screening; to assist in diagnosing diseases such as diabetes.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube; urine (5 mL) from an unpreserved random specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Freezing point depression)

	Conventional Units	SI Units (Conventional Units × 1)
Serum	275–295 mOsm/kg	275–295 mmol/kg
Urine		
Newborn	75–300 mOsm/kg	75–300 mmol/kg
Children and adults	250–900 mOsm/kg	250–900 mmol/kg

DESCRIPTION: Osmolality is the number of particles in a solution; it is independent of particle size, shape, and charge. Measurement of osmotic concentration in serum provides clinically useful information about water and dissolved-particle transport across fluid compartment membranes. Osmolality is used to assist in the diagnosis of metabolic, renal, and endocrine disorders. The simultaneous determination of serum and urine osmolality provides the opportunity to compare values between the two fluids. A normal urine-to-serum ratio is approximately 0.2 to 4.7 for random samples and greater than 3.0 for first-morning samples (dehydration normally occurs overnight). The major dissolved particles that contribute to osmolality are sodium, chloride, bicarbonate, urea, and glucose. Some of these substances are used in the following calculated estimate:

$$\text{Serum osmolality} = (2 \times \text{Na}^+) + (\text{glucose}/18) + (\text{BUN}/2.8)$$

Measured osmolality is higher than the estimated value. The osmolal gap is the difference between the measured and calculated values and is normally 5 to 10 mOsm/kg. If the difference is greater than 15 mOsm/kg, consider ethylene glycol, isopropanol, methanol, or ethanol toxicity. These substances behave like antifreeze, lowering the freezing point in the blood, and provide misleadingly high results.

This procedure is contraindicated for: N/A

INDICATIONS

Serum

- Assist in the evaluation of antidiuretic hormone (ADH) function
- Assist in rapid screening for toxic substances, such as ethylene glycol, ethanol, isopropanol, and methanol
- Evaluate electrolyte and acid-base balance
- Evaluate state of hydration

Urine

- Evaluate concentrating ability of the kidneys
- Evaluate diabetes insipidus
- Evaluate neonatal patients with protein or glucose in the urine
- Perform work-up for renal disease

POTENTIAL DIAGNOSIS**Increased in**

- Serum
 - Azotemia (*related to accumulation of nitrogen-containing waste products that contribute to osmolality*)
 - Dehydration (*related to hemoconcentration*)
 - Diabetes insipidus (*related to excessive loss of water through urination that results in hemoconcentration*)
 - Diabetic ketoacidosis (*related to excessive loss of water through urination that results in hemoconcentration*)
 - Hypercalcemia (*related to electrolyte imbalance that results in water loss and hemoconcentration*)
 - Hyponatremia (*related to insufficient intake of water or excessive loss of water; sodium is a major cation in the determination of osmolality*)
- Urine
 - Amyloidosis
 - Azotemia (*related to decrease in renal blood flow; decrease in water excreted by the kidneys results in a more concentrated urine*)
 - Congestive heart failure (*decrease in renal blood flow related to diminished cardiac output; decrease in water excreted by the kidneys results in a more concentrated urine*)
 - Dehydration (*related to decrease in water excreted by the kidneys that results in a more concentrated urine*)
 - Hyponatremia
 - Syndrome of inappropriate antidiuretic hormone production (SIADH) (*related to decrease in water excreted by the kidneys that results in a more concentrated urine*)

Decreased in

- Serum
 - Adrenocorticoid insufficiency

Hyponatremia (*sodium is a major influence on osmolality; decreased sodium contributes to decreased osmolality*)
 SIADH (*related to increase in water reabsorbed by the kidneys that results in a more dilute serum*)
 Water intoxication (*related to excessive water intake, which has a dilutional effect*)

- Urine
 - Diabetes insipidus (*related to decreased ability of the kidneys to concentrate urine*)
 - Hypertatremia (*related to increased water excreted by the kidneys that results in a more dilute urine*)
 - Hypokalemia (*related to increased water excreted by the kidneys that results in a more dilute urine*)
 - Primary polydipsia (*related to increase in water intake that results in dilute urine*)

CRITICAL FINDINGS **Serum**

- Less than 265 mOsm/kg (SI: Less than 265 mmol/kg)
- Greater than 320 mOsm/kg (Greater than 320 mmol/kg)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record

with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Serious clinical conditions may be associated with elevated or decreased serum osmolality. The following conditions are associated with elevated serum osmolality:

- **Respiratory arrest:** 360 mOsm/kg
- **Stupor of hyperglycemia:** 385 mOsm/kg
- **Grand mal seizures:** 420 mOsm/kg
- **Death:** greater than 420 mOsm/kg

Symptoms of critically high levels include poor skin turgor, listlessness, acidosis (decreased pH), shock, seizures, coma, and cardiopulmonary arrest. Intervention may include close monitoring of electrolytes, administering intravenous fluids with the appropriate composition to shift water either into or out of the intravascular space as needed, monitoring cardiac signs, continuing neurological checks, and taking seizure precautions.

INTERFERING FACTORS

- Drugs that may increase serum osmolality include corticosteroids, glycerin, inulin, ioxitalamic acid, mannitol, and methoxyflurane.
- Drugs that may decrease serum osmolality include bendroflumethiazide, carbamazepine, chlorpromazine, chlorthalidone, cyclophosphamide, cyclothiazide, doxepin, hydrochlorothiazide, lorcaïnide, methyclothiazide, and polythiazide.
- Drugs that may increase urine osmolality include anesthetic agents, chlorpropamide, cyclophosphamide, furosemide, mannitol, metolazone, octreotide, phloridzin, and vincristine.
- Drugs that may decrease urine osmolality include captopril, demeclocycline, glyburide, lithium,

methoxyflurane, octreotide, tolazamide, and verapamil.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that the test is used to evaluate electrolyte and water balance.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that blood specimen collection takes approximately 5 to 10 min; random urine collection takes approximately 5 min and depends on the cooperation of the patient. Urine specimen collection may also be timed. Address concerns about pain and explain that there may be some discomfort during the venipuncture; there will be no discomfort during urine collection.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Direct the patient to breathe normally and to avoid unnecessary movement during the venipuncture.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics,

initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture as appropriate.

Blood

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

Urine

- ▶ Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device.
- ▶ Either a random specimen or a timed collection may be requested. For timed specimens, a 12- or 24-hr time frame for urine collection may be ordered. Inform the patient that all urine must be saved during that 12- or 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- ▶ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling Catheter

- ▶ Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before

specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Blood or Urine

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Decreased osmolality may be associated with overhydration. Observe the patient for signs and symptoms of fluid-volume excess related to excess electrolyte intake, fluid-volume deficit related to active body fluid loss, or risk of injury related to an alteration in body chemistry. (For electrolyte-specific dietary references, see monographs titled "Chloride," "Potassium," and "Sodium.")
- ▶ Increased osmolality may be associated with dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric and other patients in whom renal function has deteriorated.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the National Kidney Foundation (www.kidney.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, anion gap, ammonia, ADH, ANP, BNP, BUN,

calcium, carbon dioxide, chloride, CBC hematocrit, CBC hemoglobin, cortisol, creatinine, echocardiography, echocardiography transesophageal, ethanol, glucose, ketones, lung perfusion scan,

magnesium, phosphorus, potassium, sodium, and UA.

Refer to the Endocrine and Genitourinary systems tables at the end of the book for related tests by body system.

Osmotic Fragility

SYNONYM/ACRONYM: Red blood cell osmotic fragility, OF

COMMON USE: To assess the fragility of erythrocytes related to red blood cell lysis toward diagnosing diseases such as hemolytic anemia.

SPECIMEN: Whole blood (1 mL) collected in a green-top (heparin) tube and two peripheral blood smears.

NORMAL FINDINGS: (Method: Spectrophotometry) Hemolysis (unincubated) begins at 0.5% sodium chloride (NaCl) solution and is complete at 0.3% NaCl solution. Results are compared to a normal curve.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Conditions that produce RBCs with a small surface-to-volume ratio or RBCs that are rounder than normal will have increased osmotic fragility.

- Acquired immune hemolytic anemias (*abnormal RBCs in size and shape; spherocytes*)
- Hemolytic disease of the newborn (*abnormal RBCs in size and shape; spherocytes*)
- Hereditary spherocytosis (*abnormal RBCs in size and shape; spherocytes*)
- Malaria (*related to effect of parasite on RBC membrane integrity*)
- Pyruvate kinase deficiency (*abnormal RBCs in size and shape; spherocytes*)

Decreased in

Conditions that produce RBCs with a large surface-to-volume ratio or RBCs that are flatter than normal will have decreased osmotic fragility.

- Asplenia (*abnormal cells are not removed from circulation due to absence of spleen; target cells*)
- Hemoglobinopathies (*abnormal RBCs in size and shape; target cells, drepanocytes*)
- Iron-deficiency anemia (*abnormal RBCs in size and shape; target cells*)
- Liver disease (*abnormal RBCs in size and shape; target cells*)
- Thalassemias (*abnormal RBCs in size and shape; target cells*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Osteocalcin

SYNONYM/ACRONYM: Bone GLA protein, BGP.

COMMON USE: To assist in assessment of risk for osteoporosis and to evaluate effectiveness of therapeutic interventions.

SPECIMEN: Serum (1 mL) collected in a red-top tube. Serum from a gold-, red/gray-top tube; plasma from a lavender (EDTA)-pink (K2EDTA), or green (sodium or lithium heparin)-top tube is also acceptable.

NORMAL FINDINGS: (Method: Electrochemiluminescence)

Age and Sex	Conventional Units	SI Units (Conventional Units × 1)
6 mo–6 yr		
Male	39–121 ng/mL	39–121 mcg/L
Female	44–130 ng/mL	44–130 mcg/L
7–9 yr		
Male	66–182 ng/mL	66–182 mcg/L
Female	73–206 ng/mL	73–206 mcg/L
10–12 yr		
Male	85–232 ng/mL	85–232 mcg/L
Female	77–262 ng/mL	77–262 mcg/L
13–15 yr		
Male	70–336 ng/mL	70–336 mcg/L
Female	33–222 ng/mL	33–222 mcg/L
16–17 yr		
Male	43–237 ng/mL	43–237 mcg/L
Female	24–99 ng/mL	24–99 mcg/L
Adult		
Male	3–40 ng/mL	3–40 mcg/L
Female		
Premenopausal	5–30 ng/mL	5–30 mcg/L
Postmenopausal	9–50 ng/mL	9–50 mcg/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Adolescents undergoing a growth spurt (**levels in the blood increase as the rate of bone formation increases**)
- Chronic renal failure (**related to accumulation in circulation due to decreased renal excretion**)
- Hyperthyroidism (primary and secondary) (**related to increased bone turnover**)
- Metastatic skeletal disease (**levels in the blood increase as bone destruction releases it into circulation**)

- Paget's disease (*levels in the blood increase as bone destruction releases it into circulation*)
- Renal osteodystrophy (*related to bone degeneration secondary to hyperparathyroidism of chronic renal failure*)
- Some patients with osteoporosis (*levels in the blood increase as bone destruction releases it into circulation*)

Decreased in

- Growth hormone deficiency (*bone mineralization is stimulated by growth hormone*)
- Pregnancy (*increased demand by developing fetus results in an increase in maternal bone resorption*)
- Primary biliary cirrhosis (*related to increased bone loss*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Otoscopy

SYNONYM/ACRONYM: N/A.

COMMON USE: To visualize and assess internal and external structures of the ear to evaluate for pain or hearing loss.

AREA OF APPLICATION: Ears.

CONTRAST: N/A.

DESCRIPTION: This noninvasive procedure is used to inspect the external ear, auditory canal, and tympanic membrane. Otoscopy is an essential part of any general physical examination but is also done before any other audiological studies when symptoms of ear pain or hearing loss are present.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect causes of deafness, obstruction, stenosis, or swelling of the pinna or canal causing a narrowing or closure that prevents sound from entering

- Detect ear abnormalities during routine physical examination
- Diagnose cause of ear pain
- Remove impacted cerumen (with a dull ring curette) or foreign bodies (with a forceps) that are obstructing the entrance of sound waves into the ear
- Evaluate acute or chronic otitis media and effectiveness of therapy in controlling infections

POTENTIAL DIAGNOSIS

Normal findings in

- Normal structure and appearance of the external ear, auditory canal, and tympanic membrane.
Pinna: Funnel-shaped cartilaginous structure; no evidence of infection, pain, dermatitis with swelling, redness, or itching

External auditory canal: S-shaped canal lined with fine hairs, sebaceous and ceruminous glands; no evidence of redness, lesions, edema, scaliness, pain, accumulation of cerumen, drainage, or presence of foreign bodies

Tympanic membrane: Shallow, circular cone that is shiny and pearl gray in color, semitransparent whitish cord crossing from front to back just under the upper edge, cone of light on the right side at the 4 o'clock position; no evidence of bulging, retraction, lusterless membrane, or obliteration of the cone of light

Abnormal findings in

- Cerumen accumulation
- Ear trauma
- Foreign bodies
- Otitis externa
- Otitis media
- Tympanic membrane perforation or rupture

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Obstruction of the auditory canal with cerumen, dried drainage, or foreign bodies that prevent introduction of the otoscope.

other tests and procedures to assess and diagnose auditory deficit. Obtain a history of the patient's complaints of pain, itching, drainage, deafness, or presence of tympanotomy tube.

- ▶ Obtain a history of symptoms and results of previously performed laboratory tests, diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, especially antibiotic regimen, as well as herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the caregiver that he or she may need to restrain a child in order to prevent damage to the ear if the child cannot remain still. Address concerns about pain and explain that no discomfort will be experienced during the test. Inform the patient that a health-care provider (HCP) performs the test and that to evaluate both ears, the test can take 5 to 10 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Ensure that the external auditory canal is clear of impacted cerumen.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Administer ear drops or irrigation to prepare for cerumen removal, if ordered.
- ▶ Place adult patient in a sitting position; place a child in a supine position on the caregiver's lap. Request that the patient remain very still during the examination. If the patient is a child, the caregiver should be informed that he or she may need to restrain the child in order to prevent damage to the ear if the child cannot remain still.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in investigating suspected ear disorders.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's known or suspected hearing loss, including type and cause; ear conditions with treatment regimens; ear surgery; and

- Administer ear drops or irrigation to prepare for cerumen removal, if ordered. Assemble the otoscope with the correct-size speculum to fit the size of the patient's ear, and check the light source. For the adult, tilt the head slightly away and, with the nondominant hand, pull the pinna upward and backward. For a child, hold the head steady or have the caregiver hold the child's head steady, depending on the age, and pull the pinna downward. The HCP performing the examination would gently and slowly insert the speculum into the ear canal downward and forward with the handle of the otoscope held downward. For the child, hold the handle upward while placing the edge of the hand holding the otoscope on the head to steady it during insertion. If the speculum resists insertion, withdraw and attach a smaller one.
- Place an eye to the lens of the otoscope, turn on the light source, and advance the speculum into the ear canal until the tympanic membrane is visible. Examine the posterior and anterior membrane, cone of light, outer rim (annulus), umbo, handle of the malleus, folds, and pars tensa.
- Culture any effusion with a sterile swab and culture tube (see "Culture, Bacterial, Ear" monograph); alternatively, an HCP will perform a needle aspiration from the middle ear through the tympanic membrane during the examination. Other procedures such as cerumen and foreign body removal can also be performed.
- Pneumatic otoscopy can be done to determine tympanic membrane flexibility. This test permits the introduction of air

into the canal that reveals a reduction in movement of the membrane in otitis media and absence of movement in chronic otitis media.

POST-TEST:

- Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- Administer ear drops of a soothing oil, as ordered, if the canal is irritated by removal of cerumen or foreign bodies.
- Recognize anxiety related to test results, and be supportive of impaired activity related to hearing loss. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include antimicrobial drugs, audiometry hearing loss, culture bacterial (ear), and Gram stain.
- Refer to the Auditory System table at the end of the book for related tests by body system.

Ova and Parasites, Stool

SYNONYM/ACRONYM: O & P.

COMMON USE: To assess for the presence of parasites, larvae, or eggs in stool to assist in diagnosing a parasitic infection.

SPECIMEN: Stool collected in a clean plastic, tightly capped container.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination) No presence of parasites, ova, or larvae.

DESCRIPTION: This test evaluates stool for the presence of intestinal parasites and their eggs. Some parasites are nonpathogenic; others, such as protozoa and worms, can cause serious illness.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of parasitic infestation.

POTENTIAL DIAGNOSIS

Positive findings in

- Amebiasis—*Entamoeba histolytica* infection
- Ascariasis—*Ascaris lumbricoides* infection
- Blastocystis—*Blastocystis hominis* infection
- Cryptosporidiosis—*Cryptosporidium parvum* infection
- Enterobiasis—*Enterobius vermicularis* (pinworm) infection
- Giardiasis—*Giardia lamblia* infection
- Hookworm disease—*Ancylostoma duodenale*, *Necator americanus* infection

- Isospora—*Isospora belli* infection
- Schistosomiasis—*Schistosoma baematobium*, *S. japonicum*, *S. mansoni* infection
- Strongyloidiasis—*Strongyloides stercoralis* infection
- Tapeworm disease—*Diphyllobothrium*, *Hymenolepiasis*, *Taenia saginata*, *T. solium* infection
- Trematode disease—*Clonorchis sinensis*, *Fasciola hepatica*, *Fasciolopsis buski* infection
- Trichuriasis—*Trichuris trichiura* infection

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Failure to test a fresh specimen may yield a false-negative result.
- Antimicrobial or antiamebic therapy within 10 days of test may yield a false-negative result.
- Failure to wait 1 wk after a gastrointestinal study using barium or after laxative use can affect test results.
- Medications such as antacids, antibiotics, antidiarrheal compounds, bismuth, castor oil, iron, magnesium, or psyllium fiber (Metamucil) may interfere with analysis.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Infection (tapeworm) <i>(Related to drinking contaminated water; eating food contaminated with fecal matter infested with larva; eating raw</i>	It is possible that there will be no symptoms; nausea; poor appetite; weakness; abdominal pain; diarrhea; weight loss secondary to inadequate nutrient	Administer prescribed tapeworm medication (praziquantel, albendazole, nitazoxanide); provide education on how to prevent an infection

Problem	Signs & Symptoms	Interventions
<i>or uncooked meat from an infected animal)</i>	absorption; fever; the presence of a cystic mass or lumps; allergic reactions to the larvae; bacterial infections; neurologic symptoms; seizures	reoccurrence; emphasize vigilant handwashing
Infection (Giardiasis) (<i>Related to contact with infected fecal contaminated food, water, or soil; swallowing infected water while swimming [lakes, rivers, streams]; eating uncooked food containing Giardiasis</i>)	Diarrhea; greasy stools; gas; nausea; abdominal pain/ cramps; dehydration	Administer prescribed IV fluids and antibiotics; encourage drinking oral liquids; explain the symptoms of dehydration to be monitored for (especially in children); provide education on how to prevent an infection reoccurrence; teach the patient that family members should stay away from those infected with Giardiasis; emphasize vigilant handwashing
Pain (<i>Related to intestinal infection; inflammation; diarrhea</i>)	Self-report of abdominal pain; abdominal bloating; abdominal cramping; emotional symptoms of distress; crying; agitation; facial grimace; moaning; irritability; disturbed sleep; diaphoresis; altered blood pressure and heart rate; nausea; vomiting	Collaborate with the patient and physician to identify the best pain management modality to provide relief; ensure compliance with taking ordered antibiotic to clear parasitic infection; refrain from activities that may aggravate pain; use the application of heat or cold to the best effect in managing the pain; monitor pain severity
Nutrition (<i>Related to ingestion of parasitic contaminated food, water</i>)	Positive stool culture for parasitic infection	Teach the patient to abstain from eating raw food; teach the patient and family to

(table continues on page 1206)

Problem

Signs & Symptoms

Interventions

use vigilant handwashing before meals; emphasize the importance of using clean water for food preparation and drinking

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing a parasitic infection.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens. Document any travel to foreign countries.
- ▶ Obtain a history of the patient's gastrointestinal and immune systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent therapies that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Instruct the patient on hand-washing procedures, and inform the patient that the infection may be contagious. Warn the patient not to contaminate the specimen with urine, toilet paper, or toilet water. Address concerns about pain and explain to the patient that there should be no discomfort during the procedure.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to avoid medications that interfere with test results.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Collect a stool specimen directly into the container. If the patient is bedridden, use a clean bedpan and transfer the specimen into the container using a tongue depressor.
- ▶ Specimens to be examined for the presence of pinworms are collected by the "Scotch tape" method in the morning before bathing or defecation. A small paddle with a piece of cellophane tape (sticky side facing out) is pressed against the perianal area. The tape is placed in a collection container and submitted to determine if ova are present. Sometimes adult worms are observed protruding from the rectum.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- Educate the patient with positive findings on the transmission of the parasite, as indicated.
- Warn the patient that one negative result does not rule out parasitic infestation and that additional specimens may be required.
- Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- States the importance of good hand hygiene to decrease risk of parasitic infection

States understanding that anal itching during the nighttime could indicate a enterobiasis (pinworm) infection

Skills

- Demonstrates proficient handwashing
- Describes changes in food and water handling that will need to be taken to prevent parasitic infection

Attitude

- Complies with the request to clean surfaces to help prevent an ova and parasite infection
- Complies with the recommendation to take the entire amount of prescribed antibiotics as appropriate to treat infection

RELATED MONOGRAPHS:

- Related tests include biopsy intestinal, biopsy liver, biopsy muscle, culture stool, fecal analysis, and IgE.
- Refer to the Gastrointestinal and Immune systems tables at the end of the book for related tests by body system.

Oxalate, Urine

SYNONYM/ACRONYM: N/A.

COMMON USE: To identify patients who are at risk for renal calculus formation or hyperoxaluria related to malabsorption.

SPECIMEN: Urine (25 mL) from a timed specimen collected in a clean plastic collection container with hydrogen chloride (HCl) as a preservative.

NORMAL FINDINGS: (Method: Spectrophotometry)

	Conventional Units	SI Units (Conventional Units × 11.1)
Children and adults	0–40 mg/24 hr	0–444 micromol/24 hr

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Conditions that result in malabsorption for any reason can lead to increased levels. Chronic diarrhea results in excessive loss of calcium to bind oxalate. Increased oxalate is absorbed by the intestine and excreted by the kidneys.

- Bacterial overgrowth
- Biliary tract disease
- Bowel disease
- Celiac disease
- Cirrhosis
- Crohn's disease
- Diabetes
- Ethylene glycol poisoning (*ethylene glycol is metabolized to oxalate*)

and excreted by the kidneys; crystals are present in urine)

- Ileal resection
- Jejunum shunt
- Pancreatic disease
- Primary hereditary hyperoxaluria (rare)
- Pyridoxine (vitamin B₆) deficiency (*pyridoxine is a cofactor in an enzyme reaction that converts glyoxylic acid to glycine; deficiency results in an increase in oxalate*)
- Sarcoidosis

Decreased in

- Hypercalciuria (*related to formation of calcium oxalate crystals*)
- Renal failure (*related to oxalate kidney stone disease*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Pachymetry

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess the thickness of the cornea prior to LASIK surgery and evaluate glaucoma risk.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Normal findings in

- Normal corneal thickness of 535 to 555 micron

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Abnormal findings in

- Bullous keratopathy
- Corneal rejection after penetrating keratoplasty
- Fuchs' endothelial dystrophy
- Glaucoma

CRITICAL FINDINGS: N/A

Papanicolaou Smear

SYNONYM/ACRONYM: Pap smear, cervical smear.

COMMON USE: To establish a cytological diagnosis of cervical and vaginal disease and identify the presence of genital infections, such as human papillomavirus, herpes, and cytomegalovirus.

SPECIMEN: Cervical and endocervical cells.

NORMAL FINDINGS: Method: (Microscopic examination of fixed and stained smear) Reporting of Pap smear findings may follow one of several formats and may vary by laboratory. Simplified content of the two most common formats for interpretation are listed in the table.

Bethesda System

Specimen type:

Smear, liquid-based, or other.

Specimen adequacy:

- **Satisfactory** for evaluation—endocervical transformation zone component is described as present or absent, along with other quality indicators (e.g., partially obscuring blood, inflammation).

(table continues on page 1210)

Bethesda System

- **Unsatisfactory** for evaluation—either the specimen is rejected and the reason given or the specimen is processed and examined but not evaluated for epithelial abnormalities and the reason is given.

General categorization:

- **Negative for intraepithelial lesion or malignancy.**
- **Epithelial cell abnormality** (abnormality is specified in the interpretation section of the report).
- **Other comments**

Interpretation/result:

1. Negative for intraepithelial lesion or malignancy
 - A. **List organisms causing infection:**
 - *Trichomonas vaginalis*; fungal organisms consistent with *Candida* spp.; shift in flora suggestive of bacterial vaginosis; bacteria morphologically consistent with *Actinomyces* spp.; cellular changes consistent with herpes simplex virus
 - B. **Other nonneoplastic findings:**
 - Reactive cellular changes associated with inflammation, radiation, intrauterine device; glandular cell status post-hysterectomy; atrophy.
2. Epithelial cell abnormalities
 - A. **Squamous cell abnormalities**
 - ASC of undetermined significance (ASC-US) cannot exclude HSIL (ASC-H)
 - LSIL encompassing HPV, mild dysplasia, CIN 1
 - HSIL encompassing moderate and severe dysplasia, CIS/CIN 2 and CIN 3 with features suspicious for invasion (if invasion is suspected)
 - Squamous cell carcinoma
 - B. **Glandular cell**
 - Atypical glandular cells (NOS or specify otherwise)
 - Atypical glandular cells, favor neoplastic (NOS or specify otherwise)
 - Endocervical adenocarcinoma in situ
 - Adenocarcinoma
3. Other
 - A. Endometrial cells (in a woman of 40 yr or greater)

Automated review:

Indicates the case was examined by an automated device and the results are listed along with the name of the device.

Ancillary testing:

Describes the test method and result.

Educational notes and suggestions:

Should be consistent with clinical follow-up guidelines published by professional organizations with references included.

ASC = atypical squamous cells; ASC-H = high-grade atypical squamous cells; ASC-US = atypical squamous cells undetermined significance; CIN = cervical intraepithelial neoplasia; CIS = carcinoma in situ; HSIL = high-grade squamous intraepithelial lesion; LSIL = low-grade squamous intraepithelial lesion.

DESCRIPTION: The Papanicolaou (Pap) smear is primarily used for the early detection of cervical cancer. The interpretation of Pap smears is as heavily dependent on the collection and fixation technique as it is on the completeness and accuracy of the clinical information provided with the specimen. The patient's age, date of last menstrual period, parity, surgical status, postmenopausal status, use of hormone therapy (including use of oral contraceptives), history of radiation or chemotherapy, history of abnormal vaginal bleeding, and history of previous Pap smears are essential for proper interpretation. Human papillomavirus (HPV) is the most common sexually transmitted virus and primary causal factor in the development of cervical cancer. Therefore, specimens for HPV are often collected simultaneously with the PAP smear. The laboratory should be consulted about the availability of this option prior to specimen collection because specific test kits are required to allow for simultaneous sample collection. HPV infection can be successfully treated once it has been identified. Gardasil, the first vaccine developed against HPV, is given in three doses, at 2 and 6 mo after the initial injection. The Centers for Disease Control and Prevention recommends vaccination for males and females age 11 and 12 yr. Vaccination is also recommended for females age 13 to 26 yr and males age 13 to 21 yr who have not been previously vaccinated. Cervarix is a second HPV vaccine available only for females.

A wet prep can be prepared simultaneously from a cervical or vaginal sample. The swab is

touched to a microscope slide, and a small amount of saline is dropped on the slide. The slide is examined by microscope to determine the presence of harmful bacteria or *Trichomonas*.

A Schiller's test entails applying an iodine solution to the cervix. Normal cells pick up the iodine and stain brown. Abnormal cells do not pick up any color.

Improvements in specimen preparation have added to the increased quality of screening procedures. Liquid-based Pap tests have largely replaced the traditional Pap smear. Cervical cells collected in the liquid media are applied in a very thin layer onto slides, using a method that clears away contaminants such as blood or vaginal discharge. Samples can be "split" so that questionable findings by cytological screening can be followed up with more specific molecular methods like nucleic acid hybridization probes, polymerase chain reaction, intracellular microRNA quantification, or immunocytochemistry to detect the presence of high-risk HPV, *Chlamydia trachomatis*, and *Neisseria gonorrhoeae*. Computerized scanning systems are also being used to reduce the number of smears that require manual review by a cytotechnologist or pathologist.

There are now some alternatives to cone biopsy and cryosurgery for the treatment of cervical dysplasia. Patients with abnormal Pap smear results may have a cervical loop electrosurgical excision procedure (LEEP) performed to remove or destroy abnormal cervical tissue. In the LEEP procedure, a speculum is

inserted into the vagina, the cervix is numbed, and a special electrically charged wire loop is used to painlessly remove the suspicious area. Postprocedure cramping and bleeding can occur. Laser ablation is another technique that can be employed for the precise removal of abnormal cervical tissue.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of cervical dysplasia
- Assist in the diagnosis of endometriosis, condyloma, and vaginal adenosis
- Assist in the diagnosis of genital infections (herpes, *Candida* spp., *Trichomonas vaginalis*, cytomegalovirus, *Chlamydia*, lymphogranuloma venereum, HPV, and *Actinomyces* spp.)
- Assist in the diagnosis of primary and metastatic neoplasms
- Evaluate hormonal function

POTENTIAL DIAGNOSIS

Positive findings in
(See table [Bethesda system])

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- The smear should not be allowed to air dry before fixation.
- Lubricating jelly should not be used on the speculum.
- Improper collection site may result in specimen rejection. Samples for cancer screening are obtained from the posterior vaginal fornix and from the cervix. Samples for hormonal evaluation are obtained from the vagina.
- Douching, sexual intercourse, using tampons, or using vaginal medication within 24 hr prior to specimen collection can interfere with the specimen's results.
- Collection of other specimens prior to the collection of the Pap smear may be cause for specimen rejection.
- Contamination with blood from samples collected during the patient's menstrual period may be cause for specimen rejection.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Sexuality (<i>Related to alterations in sexual role secondary to sexually transmitted infection</i>)	Hesitancy to discuss sexual relationship with significant other	Facilitate a discussion of realistic changes to sexual intimacy associated with sexually transmitted infection; provide a relaxed atmosphere in which to discuss sexuality concerns; provide contact information for a support group

Problem	Signs & Symptoms	Interventions
Infection (<i>Related to unprotected sexual activity; lack of knowledge to take precautions to prevent infection</i>)	Genital warts	Administer prescribed medication for wart removal (antimitotic gel, immune-enhancing cream); explain to the patient that sometimes the warts will clear on their own
Fear (<i>Related to potential terminal diagnosis secondary to development of cancer</i>)	Verbalization of fear; restlessness; increased tension; continuous questioning; increased blood pressure, heart rate, respiratory rate	Evaluate verbal and nonverbal indicators of fear; assess for the cause of fear; acknowledge the patient's awareness of his or her fear; explain all procedures with simple age- and cultural-appropriate language; administer proscribed mild tranquilizer; maintain a confident, assured professional manner in all patient interactions
Knowledge (<i>Related to new condition or diagnosis; lack of familiarity or understanding with disease and treatment</i>)	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management	Identify sexual orientation; teach the process of disease transmission; teach that infection risk increases with the number of sexual partners over time; identify the patient's sexual activity; discuss importance of notifying sexual partners of disease exposure; assess for cultural, literacy, or vision and hearing concerns that would interfere with learning; administer prescribed medication; explore with the patient the value of monogamous relationship to support positive health; teach the importance of taking the prescribed medication in its entirety to resolve infection

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in diagnosing disease of the reproductive system.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Instruct the patient to avoid douching or sexual intercourse for 24 hr before specimen collection. Verify that the patient is not menstruating. Address concerns about pain and explain that there may be some discomfort during the procedure. Inform the patient that specimen collection is performed by a health-care provider (HCP) specializing in this procedure and takes approximately 5 to 10 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ Note that if the patient is taking vaginal antibiotic medication, testing should be delayed for 1 mo after the treatment has been completed.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:**Potential Complications:** N/A

- ▶ Have the patient void before the procedure.
- ▶ Have the patient remove clothes below the waist.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to breathe normally and to avoid unnecessary movement during the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.
- ▶ Assist the patient into a lithotomy position on a gynecological examination table (with feet in stirrups). Drape the patient's legs.
- ▶ A plastic or metal speculum is inserted into the vagina and is opened to gently spread apart the vagina for inspection of the cervix. The speculum may be dipped in warm water to aid in comfortable insertion.
- ▶ After the speculum is properly positioned, the cervical and vaginal specimens are obtained. A synthetic fiber brush is inserted deep enough into the cervix to reach the endocervical canal. The brush is then rotated one turn and removed. A plastic or wooden spatula is used to lightly scrape the cervix and vaginal wall.

Conventional Collection

- ▶ Specimens from both the brush and the spatula are plated on the glass slide. The brush specimen is plated using a gentle rolling motion, whereas the spatula specimen is plated using a light gliding motion across the slide. The specimens are immediately fixed to the slide with a liquid or spray containing 95% ethanol. The speculum is removed from the vagina. A pelvic and/or rectal

examination is usually performed after specimen collection is completed.

ThinPrep Collection

- ▶ The ThinPrep bottle lid is opened and removed, exposing the solution. The brush and spatula specimens are then gently swished in the ThinPrep solution to remove the adhering cells. The brush and spatula are then removed from the ThinPrep solution, and the bottle lid is replaced and secured.

Chlamydia Vaginal Swab Collection Followed by NAA

- ▶ *Care provider specimen:* Collect vaginal fluid sample using the Gen-Probe APTIMA Vaginal Swab Kit by contacting the swab to the lower third of the vaginal wall, rotating the swab for 10 to 30 sec to absorb the fluid. Immediately place the swab into the transport tube, and carefully break the swab shaft against the side of the tube. Tightly screw on the cap.
- ▶ *Patient self-collection instructions:* Partially open the package. Do not touch the soft tip or lay the swab down. If the soft tip is touched, the swab is laid down, or the swab is dropped, use a new APTIMA Vaginal Swab Specimen Collection Kit. Remove the swab. Carefully insert the swab into the vagina about 2" past the introitus, and gently rotate the swab for 10 to 30 sec, making sure the swab touches the walls of the vagina so that moisture is absorbed by the swab. Withdraw the swab without touching the skin. Immediately place the swab into the transport tube, and carefully break the swab shaft against the side of the tube. Tightly screw on the cap.

Chlamydia Endocervical Swab

- ▶ Remove excess mucus from the cervical os and surrounding mucosa using the cleaning swab (white shaft swab in the package with red printing). Discard this swab. Insert the specimen collection swab (blue shaft swab in the package with green printing) into the endocervical canal. Gently rotate the swab clockwise for

10 to 30 sec in the endocervical canal to ensure adequate sampling. Withdraw the swab carefully; avoid contact with the vaginal mucosa. Remove the cap from the swab specimen transport tube, and immediately place the specimen collection swab into the transport tube. Carefully break the swab shaft at the scoreline using care to avoid splashing of the contents. Recap the swab specimen transport tube tightly.

Chlamydia Male Urethral Swab

- ▶ Note that the patient should not have urinated for at least 1 hr prior to specimen collection. Insert the specimen collection swab (blue shaft swab in the package with the green printing) 2 to 4 cm into the urethra. Gently rotate the swab clockwise for 2 to 3 sec in the urethra to ensure adequate sampling. Withdraw the swab carefully. Remove the cap from the swab specimen transport tube, and immediately place the specimen collection swab into the specimen transport tube. Carefully break the swab shaft at the scoreline using care to avoid splashing of contents. Recap the swab specimen transport tube tightly.

Urine Specimen

- ▶ Note that the patient should not have urinated for at least 1 hr prior to specimen collection. Direct patient to provide a first-catch urine (approximately 20 to 30 mL of the initial urine stream) into a urine collection cup free of any preservatives. Collection of larger volumes of urine may result in specimen dilution that may reduce test sensitivity; lesser volumes may not adequately rinse organisms into the specimen. Female patients should not cleanse the labial area prior to providing the specimen. Add urine to the APTIMA COMBO 2 urine collection device. The final volume must be between the two black lines on the device (about 2 mL).

General

- ▶ Place samples in properly labeled specimen container and promptly

transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Cleanse or allow the patient to cleanse secretions or excess lubricant (if a pelvic and/or rectal examination is also performed) from the perineal area. Provide a sanitary pad if cervical bleeding occurs.
- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.
- ▶ Decisions regarding the need for and frequency of conventional or liquid-based Pap tests or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society's (ACS) guidelines for preventing cervical cancer recommend cytological screening every 3 yr for women age 20 to 29 yr; co-testing for HPV and cytological screening every 5 yr (or cytological screening alone every 3 yr for women age 30 to 65 yr; no screening is recommended for women who have had a hysterectomy. The most current guidelines for cervical cancer screening of the general population as well as of individuals with increased risk are available from the ACS (www.cancer.org) and the American College of Obstetricians and Gynecologists (ACOG) (www.acog.org).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in

therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Provide information regarding vaccine-preventable diseases where indicated (e.g., cervical cancer and sexually transmitted diseases such as hepatitis B and human papillomavirus).
- ▶ Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac).
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ Acknowledges the prescribed medication to treat the infection should be completed in its entirety

Skills

- ▶ Displays appropriate coping skills related to changes in future sexual activity
- ▶ Demonstrates proficiency on applying prescribed medication to genital warts

Attitude

- ▶ Agrees to discuss concerns regarding the possibility of social stigma associated with diagnosis
- ▶ Agrees to notify sexual partner regarding diagnosis of infection

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy cervical, cancer antigens, *Chlamydia* group antibody, colposcopy, culture anal/genital, culture throat, culture urine, culture viral, CMV, cytology urine, laparoscopy gynecologic, US pelvis, and UA.
- ▶ Refer to the Immune and Reproductive systems tables at the end of the book for related tests by body system.

Parathyroid Hormone

SYNONYM/ACRONYM: Parathormone, PTH, intact PTH, whole molecule PTH.

COMMON USE: To assist in the diagnosis of parathyroid disease and disorders of calcium balance. Also used to monitor patients receiving renal dialysis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Specimen should be transported tightly capped and in an ice slurry.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 1)
Cord blood	Less than 3 pg/mL	Less than 3 ng/L
2–20 yr	9–52 pg/mL	9–52 ng/L
Adult	10–65 pg/mL	10–65 ng/L

DESCRIPTION: Parathyroid hormone (PTH) is secreted by the parathyroid glands in response to decreased levels of circulating calcium. PTH assists in raising serum calcium levels by:

- Stimulating the release of calcium from bone into the bloodstream
- Promoting renal tubular reabsorption of calcium and decreased reabsorption of phosphate
- Enhancing renal production of active vitamin D metabolites which increases calcium absorption in the small intestine

C-terminal and N-terminal assays were used prior to the development of reliable intact or whole molecule PTH assays. A rapid PTH assay has been developed specifically for intraoperative monitoring of PTH in the surgical treatment of primary hyperparathyroidism. Rapid PTH assays have proved valuable because the decision of whether the hyperparathyroidism

involves one or multiple glands depends on measurement of circulating PTH levels. Surgical outcomes indicate that a 50% decrease or more in intraoperative PTH from baseline measurements can predict successful treatment with up to 97% accuracy. An intraoperative decrease of less than 50% indicates the need to identify and remove additional malfunctioning parathyroid tissue. In healthy individuals, intact PTH has a circulating half-life of about 5 min. N-terminal PTH has a circulating half-life of about 2 min and is found in very small quantities. Intact and N-terminal PTH are the only biologically active forms of the hormone. Ninety percent of circulating PTH is composed of inactive C-terminal and midregion fragments. PTH is cleared from the body by the kidneys.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of hyperparathyroidism
- Assist in the diagnosis of suspected secondary hyperparathyroidism due to chronic renal failure, malignant tumors that produce ectopic PTH, and malabsorption syndromes
- Detect incidental damage or inadvertent removal of the parathyroid glands during thyroid or neck surgery
- Differentiate parathyroid and nonparathyroid causes of hypercalcemia
- Evaluate autoimmune destruction of the parathyroid glands
- Evaluate parathyroid response to altered serum calcium levels, especially those that result from malignant processes, leading to decreased PTH production
- Evaluate source of altered calcium metabolism

POTENTIAL DIAGNOSIS**Increased in**

- Fluorosis (*skeletal fluorosis can cause a condition resembling secondary hyperparathyroidism, disruption in calcium homeostasis, and excessive PTH production*)
- Primary, secondary, or tertiary hyperparathyroidism (*all result in excess PTH production*)
- Pseudogout (*calcium is lost due to deposits in the joint; decrease in calcium stimulates PTH production*)
- Pseudohypoparathyroidism
- Zollinger-Ellison syndrome (*related to poor intestinal absorption of calcium and vitamin D; decreased calcium stimulates PTH production*)

Decreased in

- Autoimmune destruction of the parathyroids (*related to*

decreased parathyroid function)

- DiGeorge's syndrome (*related to hypoparathyroidism*)
- Hyperthyroidism (*related to increased calcium from bone loss; increased calcium levels inhibit PTH production*)
- Hypomagnesemia (*magnesium is a calcium channel blocker; low magnesium levels allow for increased calcium, which inhibits PTH production*)
- Nonparathyroid hypercalcemia (in the absence of renal failure) (*increased calcium levels inhibit PTH production*)
- Sarcoidosis (*related to increased calcium levels*)
- Secondary hypoparathyroidism due to surgery

CRITICAL FINDINGS: N/A**INTERFERING FACTORS**

- Drugs that may increase PTH levels include clodronate, estrogen/progestin therapy, foscarnet, furosemide, hydrocortisone, isoniazid, lithium, nifedipine, octreotide, pamidronate, phosphates, prednisone, tamoxifen, and verapamil.
- Drugs and vitamins that may decrease PTH levels include alfacalcidol, aluminum hydroxide, calcitriol, diltiazem, magnesium sulfate, parathyroid hormone, pindolol, prednisone, and vitamin D.
- PTH levels are subject to diurnal variation, with highest levels occurring in the morning.
- PTH levels should always be measured in conjunction with calcium for proper interpretation.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Pain (<i>Related to low circulating parathyroid hormone levels; elevated circulating parathyroid hormone secondary to hyperplasia or adenoma of the parathyroid gland</i>)	Deficit: muscle spasms; carpopedal spasms; abdominal cramping; tetany; easy fracture risk. Excess: abdominal pain; peptic ulcer formation; constipation	Monitor and trend serum calcium levels; monitor and trend serum phosphorus levels; collaborate with pharmacist and health-care provider (HCP) to pharmacologically manage calcium levels; monitor and trend serum parathyroid hormone levels
Sensory perception (<i>Related to low circulating parathyroid hormone levels</i>)	Deficit: paresthesia of lips, hands, and feet; hyperactive reflexes	Monitor and trend serum calcium levels; monitor and trend serum phosphorus levels; collaborate with pharmacist and HCP to pharmacologically manage calcium levels; monitor and trend serum parathyroid hormone levels
Nutrition (<i>Related to inability to digest foods, metabolize foods, ingest foods; refusal to eat; increased metabolic needs associated with disease process; lack of understanding; inability to obtain healthy foods</i>)	Unintended weight loss; current weight is 20% below ideal weight; pale dry skin; dry mucous membranes; documented inadequate caloric intake; subcutaneous tissue loss; hair pulls out easily; paresthesia	Record accurate daily weight at the same time each day with the same scale; obtain an accurate nutritional history; assess attitude toward eating; promote a dietary consult to evaluate current eating habits and best method of nutritional supplementation; develop short-term and long-term eating strategies; monitor nutritional laboratory values such as albumin, transferrin, RBC, WBC, and serum electrolytes; discourage caffeinated and carbonated beverages; assess swallowing ability; encourage cultural home foods; provide a pleasant environment for eating; alter food seasoning to enhance flavor; administer parenteral or enteral nutrition as prescribed

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing parathyroid disease.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. In most patients with primary hyperparathyroidism, it is usually a single gland, rather than multiple of the four glands present, that is abnormal. Removal of abnormal glands, combined with intraoperative PTH monitoring, has become the surgical treatment of choice. Inform the surgical patient that a baseline PTH level will be collected prior to resection of the abnormal parathyroid glands. Explain that additional specimens will be collected during the procedure to indicate that all abnormal parathyroid tissue has been removed and the procedure can be concluded. The protocol may vary among HCPs regarding when the baseline level should be drawn (i.e., prior to anesthesia or prior to incision). The amount of change between the baseline and intraoperative values considered adequate for determining successful, complete resection of the abnormal tissue may also vary by HCP; a decrease of 50% is typically used as a cutoff. Early-morning specimen collection is recommended because of the diurnal variation in PTH levels. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Instruct the patient to fast for 12 hr before specimen collection. Protocols may vary among facilities.
- ▶ Note that there are no fluid or medication restrictions unless by medical direction.
- ▶ Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

INTRATEST:**Potential Complications:** N/A

- ▶ Ensure that the patient has complied with dietary restrictions; ensure that food has been restricted for at least 12 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. The sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Patients with abnormal parathyroid levels are also likely to experience the effects of

calcium-level imbalances. Instruct the patient to report signs and symptoms of hypocalcemia and hypercalcemia to the HCP. (For critical values, signs, and symptoms of calcium imbalance and for nutritional information, see monographs titled “Calcium, Blood”; “Calcium, Ionized”; and “Calcium, Urine.”)

- Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient’s symptoms and other tests performed.

Patient Education:

- Instruct the patient to resume usual diet, as directed by the HCP.
- Reinforce information given by the patient’s HCP regarding further testing, treatment, or referral to another HCP.
- Recognize anxiety related to test results and answer any questions or address any concerns voiced by the patient or family.
- Teach the patient and family about the health risks associated with elevated and deficit parathyroid levels.

Expected Patient Outcomes:

Knowledge

- States symptoms of parathyroid disease that should be reported to the HCP

- States understanding of the cause of sensory perception loss associated with a deficit of parathyroid hormone

Skills

- Demonstrates proficiency in self-administration of prescribed dietary supplements
- Demonstrates proficiency in selecting a diet that supports appropriate levels of circulating serum calcium

Attitude

- Complies with recommended follow-up laboratory studies to trend the disease process and tailor therapeutic interventions
- Complies with recommendation to attend support groups to assist in disease management and coping

RELATED MONOGRAPHS:

- Related tests include ALP, arthroscopy, calcitonin, calcium, collagen cross-linked telopeptides, evoked brain potentials, fecal fat, gastric emptying scan, gastric acid stimulation, gastrin stimulation test, parathyroid scan, phosphorus, RAIU, synovial fluid analysis, TSH, thyroxine, US thyroid and parathyroid, uric acid, UA, and vitamin D.
- Refer to the Endocrine System table at the end of the book for related tests by body system.

Parathyroid Scan

SYNONYM/ACRONYM: Parathyroid scintiscan.

COMMON USE: To assess the parathyroid gland toward diagnosing cancer and to perform postoperative evaluation of the parathyroid gland.

AREA OF APPLICATION: Parathyroid.

CONTRAST: IV technetium-99m (Tc-99m) pertechnetate, Tc-99m sestamibi, oral iodine-123, and thallium.

DESCRIPTION: Parathyroid scanning is performed to assist in the preoperative localization of parathyroid adenomas in clinically proven primary hyperparathyroidism; it is useful for distinguishing between intrinsic and extrinsic parathyroid adenomas. It is also performed after surgery to verify the presence of the parathyroid gland in children, and it is done after thyroidectomy as well.

The radionuclide is administered 10 to 20 min before the imaging is performed. The thyroid and surrounding tissues should be carefully palpated.

Fine-needle aspiration biopsy guided by ultrasound is occasionally necessary to differentiate thyroid pathology, as well as pathology of other tissues, from parathyroid neoplasia.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of hyperparathyroidism
- Differentiate between extrinsic and intrinsic parathyroid adenoma but not between benign and malignant conditions
- Evaluate the parathyroid in patients with severe hypercalcemia or in patients before parathyroidectomy

POTENTIAL DIAGNOSIS

Normal findings in

- No areas of increased perfusion or uptake in the thyroid or parathyroid

Abnormal findings in

- Intrinsic and extrinsic parathyroid adenomas

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Ingestion of foods containing iodine (e.g., iodized salt) and medications containing iodine (e.g., cough syrup, potassium iodide, vitamins, Lugol's solution, thyroid replacement medications), which can decrease uptake of the radionuclide.
- Other nuclear scans or iodinated contrast medium radiographic studies done within the previous 24 to 48 hr.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in diagnosing parathyroid disease.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodinated contrast medium or radioactive nuclides.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test. Inform the patient that the procedure is performed in a nuclear medicine department, usually by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Establishing an IV site and injection of radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners;** hematoma **related to blood leakage into the tissue following needle insertion;** infection **that might occur if bacteria from the skin surface is introduced at the puncture site;** or nerve injury **that might occur if the needle strikes a nerve.**
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
 - ▶ Instruct the patient to void prior to the procedure and to change into the

gown, robe, and foot coverings provided.

- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Observe that technetium-99m (Tc-99m) pertechnetate is injected IV before scanning.
- ▶ Place the patient in a supine position under a radionuclide gamma camera. Images are preformed 15 min after the injection.
- ▶ With the patient in the same position, Tc-99m sestamibi is injected, and a second image is obtained after 10 min.
- ▶ Iodine-123 may be administered orally in place of Tc-99m pertechnetate; the imaging sequence, as described previously, is performed 24 hr later.
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Advise the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the

body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.

- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to flush the toilet immediately and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include calcitonin, calcium, CT thoracic and MRI chest, PTH, phosphorus, US thyroid and parathyroid, and vitamin D.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Partial Thromboplastin Time, Activated

SYNONYM/ACRONYM: aPTT, APTT.

COMMON USE: To assist in assessing coagulation disorders and monitor the effectiveness of therapeutic interventions.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Clot detection) 25 to 35 sec. The aPTT is normally prolonged in infants, up to 55 sec, and gradually decreases to the adult range by age 6 mo. Reference ranges vary with respect to the equipment and reagents used to perform the assay.

DESCRIPTION: The activated partial thromboplastin time (aPTT) test evaluates the function of the contact activation pathway, formerly known as intrinsic pathway (factors XII, XI, IX, VIII, prekallikrein, and high molecular weight kininogen) and the common pathway (factors V, X, II, and I) of the coagulation sequence. The aPTT time represents the time required for formation of a firm fibrin clot after tissue thromboplastin reagents and calcium are added to a plasma specimen. The aPTT is abnormal in 90% of patients with coagulation disorders and is useful in monitoring effective inactivation of factor II (thrombin) by heparin therapy. The test is prolonged when there is a 30% to 40% deficiency in one of the factors required or when factor inhibitors (e.g., antithrombin III, protein C, or protein S) are present. The aPTT and prothrombin time (PT) tests assist in identifying the cause of or tendency for bleeding as related to coagulation defects.

A comparison between the results of aPTT and PT tests can allow some inferences to be made that a factor deficiency exists. A normal aPTT with a prolonged PT can occur only with factor VII deficiency. A prolonged aPTT with a normal PT could indicate a deficiency in factors XII, XI, IX, VIII, and VIII:C (von Willebrand factor). Factor deficiencies can also be identified by correction or substitution studies using normal serum. These studies are easy to perform and are accomplished by adding plasma from a healthy patient to a sample from a patient suspected to be factor deficient. When the aPTT is repeated and is corrected, or is within the reference range, it can be assumed that the prolonged aPTT is caused by a factor deficiency. If the result remains uncorrected, the prolonged aPTT is most likely due to a circulating anticoagulant. (For more information on factor deficiencies, see the "Coagulation Factors" monograph.)

This procedure is contraindicated for: N/A

INDICATIONS

- Detect congenital deficiencies in clotting factors, as seen in diseases such as hemophilia A (factor VIII) and hemophilia B (factor IX)
- Evaluate response to anticoagulant therapy with heparin or coumarin derivatives
- Identify individuals who may be prone to bleeding during surgical, obstetric, dental, or invasive diagnostic procedures
- Identify the possible cause of abnormal bleeding, such as epistaxis, hematoma, gingival bleeding, hematuria, and menorrhagia
- Monitor the hemostatic effects of conditions such as liver disease, protein deficiency, and fat malabsorption

POTENTIAL DIAGNOSIS

Prolonged in

- Afibrinogenemia (*related to insufficient levels of fibrinogen, which is required for clotting*)
- Circulating anticoagulants (*related to the presence of coagulation factor inhibitors, e.g., developed from long-term factor VIII therapy, or circulating anticoagulants associated with conditions like tuberculosis, systemic lupus erythematosus, rheumatoid arthritis, and chronic glomerulonephritis*)
- Circulating products of fibrin and fibrinogen degradation (*related to the presence of circulating breakdown products of fibrin*)
- Disseminated intravascular coagulation (*related to increased consumption of clotting factors*)
- Factor deficiencies (*related to insufficient levels of coagulation factors*)
- Hemodialysis patients (*related to the anticoagulant effect of heparin*)

- Severe liver disease (*insufficient production of clotting factors related to liver damage*)
- Vitamin K deficiency (*related to insufficient vitamin K levels required for clotting*)
- Von Willebrand's disease (*related to a congenital deficiency of clotting factors*)

CRITICAL FINDINGS

- *Adults & children* Greater than 70 sec

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Important signs to note are prolonged bleeding from cuts or gums, hematoma at a puncture site, bruising easily, blood in the stool, persistent epistaxis, heavy or prolonged menstrual flow, and shock. Monitor vital signs, PTT levels, unusual ecchymosis, occult

blood, severe headache, unusual dizziness, and neurological changes until aPTT is within normal range.

INTERFERING FACTORS

- Drugs and vitamins such as anistreplase, antihistamines, chlorpromazine, salicylates, and ascorbic acid may cause prolonged aPTT.
- Anticoagulant therapy with heparin will prolong the aPTT.
- Copper is a component of factor V, and severe copper deficiencies may result in prolonged aPTT values.
- Traumatic venipunctures can activate the coagulation sequence by contamination of the sample with tissue thromboplastin and can produce falsely shortened results.
- Failure to fill the tube sufficiently to yield a proper blood-to-anticoagulant ratio invalidates the results and is reason for specimen rejection.
- Excessive agitation that causes sample hemolysis can falsely shorten the aPTT because the hemolyzed cells activate plasma-clotting factors.
- Inadequate mixing of the tube can produce erroneous results.
- Specimens left unprocessed for longer than 24 hr should be rejected for analysis.
- High platelet count or inadequate centrifugation will result in decreased values.
- Hematocrit greater than 55% may cause falsely prolonged results because of anticoagulant excess relative to plasma volume.
- Incompletely filled collection tubes, specimens contaminated with heparin, clotted specimens, or unprocessed specimens not delivered to the laboratory within 1 to 2 hr of collection should be rejected.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Bleeding (<i>Related to alerted clotting factors secondary to heparin use or depleted clotting factors</i>)	Altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; capillary refill greater than 3 sec; cool extremities; blood in urine, stool, sputum; bleeding gums; nosebleed; bruises easily; elevated PTT	Increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; administer prescribed vitamin K; monitor and trend HGB/HCT; assess skin for petechiae, purpura, hematoma; monitor for blood in emesis, or sputum; institute bleeding precautions (prevent unnecessary venipuncture; avoid intramuscular [IM] injections; prevent trauma; be gentle with oral care, suctioning; avoid use of a sharp razor); administer prescribed stool softener

(table continues on page 1228)

Problem	Signs & Symptoms	Interventions
Gas exchange (<i>Related to deficient oxygen capacity of the blood secondary to blood loss</i>)	Irregular breathing pattern, use of accessory muscles; altered chest excursion; adventitious breath sounds (crackles, rhonchi, wheezes, diminished breath sounds); copious secretions; signs of hypoxia; altered blood gas results; confusion; lethargy; cyanosis	Monitor respiratory rate and effort based on assessment of patient condition; assess lung sounds frequently; monitor for secretions, bloody sputum; suction as necessary; use pulse oximetry to monitor oxygen saturation; collaborate with physician to administer oxygen as needed; elevate the head of the bed 30 degrees or higher; monitor IV fluids and avoid aggressive fluid resuscitation; assess level of consciousness; anticipate the need for possible intubation
Tissue perfusion (<i>Related to decreased hemoglobin secondary to bleeding; altered clotting factors</i>)	Hypotension; dizziness; cool extremities; pallor; capillary refill greater than 3 sec in fingers and toes; weak pedal pulses; altered level of consciousness; altered sensation	Monitor blood pressure; assess for dizziness; assess extremities for skin temperature, color, warmth; assess capillary refill; assess pedal pulses; monitor for numbness, tingling, hyperesthesia, hypoesthesia; monitor and trend PT and INR; administer blood or blood products as ordered; administer vitamin K as ordered; administer IV fluids as ordered; administer fluid bolus as appropriate; administer medication to support blood pressure as ordered; monitor and trend PTT results
Health management (<i>Related to complexity of health-care system; complexity of therapeutic management; knowledge deficit; cultural family health patterns; mistrust of HCP</i>)	Inability or failure to recognize or process information toward improving health and preventing illness with associated mental and physical effects	Facilitate collaboration with HCP to develop a plan of care that supports health; ensure patient adheres to recommended medication regime; encourage patient to comply with health-care follow-up appointments

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating the effectiveness of blood clotting.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic and hepatobiliary systems, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. If the patient is receiving anticoagulant therapy, note the time and amount of the last dose.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in

Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Fill tube completely. **Important note:** When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) tubes. Otherwise, when using a standard vacuum system, the blue-top tube is the first tube collected. When a butterfly is used and due to the added tubing, an extra red-top tube should be collected before the blue-top tube to ensure complete filling of the blue-top tube.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. If delays in specimen transport and processing occur, it is important to consult with the testing laboratory. Whole blood specimens are stable at room temperature for up to 24 hr. Specimen stability requirements may also vary if the patient is receiving heparin therapy. Some laboratories require frozen plasma if testing will not be performed within 1 hr of collection. Criteria for rejection of specimens based on collection time may vary among facilities.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to report severe bruising or bleeding from any areas of the skin or mucous membranes.

- ▶ Inform the patient with prolonged aPTT values of the importance of taking precautions against bruising and bleeding, including the use of a soft-bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of acetylsalicylic acid and similar products, and avoidance of IM injections.
- ▶ Inform the patient of the importance of periodic laboratory testing while taking an anticoagulant.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States signs and symptoms of bleeding that should be reported to the HCP
- ▶ States purpose of heparin infusion in relation to medical diagnosis

Skills

- ▶ Demonstrates the proficient use of nasal spray and lip balm to prevent

cracked mucous membranes and associated bleeding

- ▶ Demonstrates proficiency in the self-examination of skin for bruising and bleeding

Attitude

- ▶ Complies with the request to refrain from at-risk behavior that would cause bleeding
- ▶ Complies with the request to refrain from using herbal supplements unless approved by the HCP due to increased bleeding risk

RELATED MONOGRAPHS:

- ▶ Related tests include antithrombin III, bleeding time, coagulation factors, CBC, CBC platelet count, copper, D-dimer, FDP, plasminogen, protein C, protein S, PT/INR, and vitamin K.
- ▶ Refer to the Hematopoietic and Hepatobiliary systems tables at the end of the book for related tests by body system.

Parvovirus B19 Immunoglobulin G and Immunoglobulin M Antibodies

SYNONYM/ACRONYM: N/A.

COMMON USE: To assist in confirming a diagnosis of a present or past parvovirus infection.

SPECIMEN: Serum (2 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Immunoassay)

Negative	Less than 0.8 index
Equivocal	0.8–1.2 index

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Positive findings in Parvovirus infection can be evidenced in a variety of conditions.

- Arthritis
- Erythema infectiosum (fifth disease)

- Erythrocyte aplasia
- Hydrops fetalis

Negative findings in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Pericardial Fluid Analysis

SYNONYM/ACRONYM: None.

COMMON USE: To evaluate and classify the type of fluid between the pericardium membranes to assist with diagnosis of infection or fluid balance disorder.

SPECIMEN: Pericardial fluid (5 mL) collected in a red- or green-top (heparin) tube for glucose, a lavender-top (EDTA) tube for cell count, and sterile containers for microbiology specimens; 200 to 500 mL of fluid in a clear container for cytology. Ensure that there is an equal amount of fixative and fluid in the container for cytology.

NORMAL FINDINGS: (Method: Spectrophotometry for glucose; automated or manual cell count, macroscopic examination of cultured organisms, and microscopic examination of specimen for microbiology and cytology; microscopic examination of cultured microorganisms)

Pericardial Fluid	Reference Value
Appearance	Clear
Color	Pale yellow
Glucose	Parallels serum values
Red blood cell count	None seen
White blood cell count	Less than 300/microL
Culture	No growth
Gram stain	No organisms seen
Cytology	No abnormal cells seen

DESCRIPTION: The heart is located within a protective membrane called the *pericardium*. The fluid between the pericardial membranes is called *serous fluid*. Normally only a small amount of fluid is present because the rates of fluid production and absorption are about the same. Many

abnormal conditions can result in the buildup of fluid within the pericardium. Specific tests are usually ordered in addition to a common battery of tests used to distinguish a transudate from an exudate. *Transudates* are effusions that form as a result of a systemic disorder that disrupts

the regulation of fluid balance, such as a suspected perforation.

Exudates are caused by conditions involving the tissue of the membrane itself, such as an

infection or malignancy. Fluid is withdrawn from the pericardium by needle aspiration and tested as listed in the previous and following tables.

Characteristic	Transudate	Exudate
Appearance	Clear	Cloudy or turbid
Specific gravity	Less than 1.015	Greater than 1.015
Total protein	Less than 2.5 g/dL	Greater than 3 g/dL
Fluid-to-serum protein ratio	Less than 0.5	Greater than 0.5
LDH	Parallels serum value	Less than 200 units/L
Fluid-to-serum LDH ratio	Less than 0.6	Greater than 0.6
Fluid cholesterol	Less than 55 mg/dL	Greater than 55 mg/dL
White blood cell count	Less than 100/microL	Greater than 1,000/microL

LDH = lactate dehydrogenase.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate effusion of unknown etiology
- Investigate suspected hemorrhage, immune disease, malignancy, or infection

POTENTIAL DIAGNOSIS

Increased in

Condition/Test Showing

Increased Result

- Bacterial pericarditis (red blood cell [RBC] count, white blood cell [WBC] count with a predominance of neutrophils)
- Hemorrhagic pericarditis (RBC count, WBC count)
- Malignancy (RBC count, abnormal cytology)
- Post-myocardial infarction syndrome, also called Dressler's syndrome (RBC count, WBC count with a predominance of neutrophils)

- Rheumatoid disease or systemic lupus erythematosus (SLE) (RBC count, WBC count)
- Tuberculous or fungal pericarditis (RBC count, WBC count with a predominance of lymphocytes)
- Viral pericarditis (RBC count, WBC count with a predominance of neutrophils)

Decreased in

Condition/Test Showing

Decreased Result

- Bacterial pericarditis (glucose)
- Malignancy (glucose)
- Rheumatoid disease or SLE (glucose)

CRITICAL FINDINGS

Positive culture findings in any sterile body fluid.

Note and immediately report to the health-care provider (HCP) positive culture results, if ordered, and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP).

A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Bloody fluid may be the result of a traumatic tap.
- Unknown hyperglycemia or hypoglycemia may be misleading in the comparison of fluid and serum glucose levels. Therefore, it is advisable to collect comparative serum samples a few hours before performing pericardiocentesis.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

- ▶ **Patient Teaching:** Inform the patient this procedure can assist with evaluating fluid around the heart.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular and immune system, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to the surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the chest wall. Explain that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the anesthetic injection may cause a stinging sensation. Explain that after the skin has been anesthetized, a large needle will be inserted through the chest to obtain the fluid. Inform the patient that specimen collection is performed by an HCP specializing in this procedure and usually takes approximately 30 min to complete.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

▶ Note that food and fluids should be restricted for 6 to 8 hr before the procedure, as directed by the HCP, unless the procedure is performed in an emergency situation to correct pericarditis. The requesting HCP may request that anticoagulants and aspirin be withheld. The number of days to withhold medication is dependent on the type of anticoagulant. Protocols may vary among facilities.

▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Pain, bleeding, swelling, infection, injury to the surrounding organs

- ▶ Ensure that the patient has complied with dietary and fluids restrictions; assure that food and fluids have been restricted for at least 6 to 8 hr prior to the procedure.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Notify the HCP if patient anticoagulant therapy has not been withheld.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void before the procedure.
- ▶ Have the patient remove clothes above the waist and put on a gown.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- ▶ Record baseline vital signs, and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.

▶ Establish an IV line to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.

- ▶ Assist the patient into a comfortable supine position with the head elevated 45° to 60°.
- ▶ Clip hair from the site as needed, cleanse the site with an antiseptic solution, and drape the area with sterile towels prior to the administration of local anesthesia. The skin at the injection site is then anesthetized.
- ▶ The precordial (V) cardiac lead wire is attached to the cardiac needle with an alligator clip. The cardiac needle is inserted just below and to the left of the breastbone, and fluid is removed.
- ▶ Monitor vital signs every 15 min for signs of hypovolemia or shock. Monitor electrocardiogram for needle-tip positioning to indicate accidental puncture of the right atrium.
- ▶ The needle is withdrawn, and slight pressure is applied to the site. Apply a sterile dressing to the site.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place samples in properly labeled specimen containers, and promptly transport the specimens to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet and medications, as directed by the HCP.
- ▶ Monitor vital signs and cardiac status every 15 min for the first hour, every 30 min for the next 2 hr, every hr for the next 4 hr, and every 4 hr for the next 24 hr. Take the patient's temperature every 4 hr for 24 hr. Monitor intake and output for 24 hr. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe/assess the patient for signs of respiratory and cardiac distress, such as shortness of breath, cyanosis, or rapid pulse.

- ▶ Continue IV fluids until vital signs are stable and the patient can resume fluid intake independently.
- ▶ Inform the patient that 1 hr or more of bed rest is required after the procedure.
- ▶ Observe/assess the puncture site for bleeding or drainage and signs of inflammation each time vital signs are taken and daily thereafter for several days. Report to HCP if bleeding is present.
- ▶ Observe/assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, if appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include AST, atrial natriuretic peptide, blood gases, B-type natriuretic peptide, cancer antigens, chest x-ray, CBC WBC count and differential, CK and isoenzymes, culture and smear mycobacteria, culture blood, culture fungal, culture viral, ECG, echocardiography, α_1 -fetoprotein, homocysteine, LDH and isoenzymes, magnesium, MRI chest, MI scan, myoglobin, and troponin.
- ▶ Refer to the Cardiovascular and Immune systems tables at the end of the book for related tests by body system.

Peritoneal Fluid Analysis

SYNONYM/ACRONYM: Ascites fluid analysis.

COMMON USE: To evaluate and classify the type of fluid within the peritoneal cavity to assist with diagnosis of cancer, infection, necrosis, and perforation.

SPECIMEN: Peritoneal fluid (5 mL) collected in a red- or green-top (heparin) tube for amylase, glucose, and alkaline phosphatase; lavender-top (EDTA) tube for cell count; sterile containers for microbiology specimens; 200 to 500 mL of fluid in a clear container with anticoagulant for cytology. Ensure that there is an equal amount of fixative and fluid in the container for cytology.

NORMAL FINDINGS: (Method: Spectrophotometry for glucose, amylase, and alkaline phosphatase; automated or manual cell count, macroscopic examination of cultured organisms, and microscopic examination of specimen for microbiology and cytology; microscopic examination of cultured microorganisms)

Peritoneal Fluid**Reference Value**

Appearance	Clear
Color	Pale yellow
Amylase	Parallels serum values
Alkaline phosphatase	Parallels serum values
CEA	Parallels serum values
Glucose	Parallels serum values
Red blood cell count	None seen
White blood cell count	Less than 300/microL
Culture	No growth
Acid-fast stain	No organisms seen
Gram stain	No organisms seen
Cytology	No abnormal cells seen

DESCRIPTION: The peritoneal cavity and organs within it are lined with a protective membrane. The fluid between the membranes is called *serous fluid*. Normally only a small amount of fluid is present because the rates of fluid production and absorption are about the same. Many abnormal conditions can result in the buildup of fluid within the peritoneal cavity. Specific tests are usually ordered in addition to a common battery of tests used to distinguish a transudate from an exudate.

Transudates are effusions that form as a result of a systemic disorder that disrupts the regulation of fluid balance, such as a

suspected perforation. *Exudates* are caused by conditions involving the tissue of the membrane itself, such as an infection or malignancy. Fluid is withdrawn from the peritoneal cavity by needle aspiration and tested as listed in the previous and following tables.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate ascites of unknown cause
- Investigate suspected peritoneal rupture, perforation, malignancy, or infection

Characteristic**Transudate****Exudate**

Appearance	Clear	Cloudy or turbid
Specific gravity	Less than 1.015	Greater than 1.015
Total protein	Less than 2.5 g/dL	Greater than 3 g/dL
Fluid-to-serum protein ratio	Less than 0.5	Greater than 0.5
LDH	Parallels serum value	Less than 200 units/L
Fluid-to-serum LDH ratio	Less than 0.6	Greater than 0.6
Fluid cholesterol	Less than 55 mg/dL	Greater than 55 mg/dL
White blood cell count	Less than 100/microL	Greater than 1,000/microL

LDH = lactate dehydrogenase.

POTENTIAL DIAGNOSIS

Increased in

Condition/Test Showing Increased Result

- Abdominal malignancy (red blood cell [RBC] count, carcinoembryonic antigen, abnormal cytology)
- Abdominal trauma (RBC count)
- Ascites caused by cirrhosis (white blood cell [WBC] count, neutrophils greater than 25% but less than 50%)
- Bacterial peritonitis (WBC count, neutrophils greater than 50%)
- Peritoneal effusion due to gastric strangulation, perforation, or necrosis (amylase, ammonia, alkaline phosphatase)
- Peritoneal effusion due to pancreatitis, pancreatic trauma, or pancreatic pseudocyst (amylase)
- Rupture or perforation of urinary bladder (ammonia, creatinine, urea)
- Tuberculous effusion (elevated lymphocyte count, positive acid-fast bacillus smear and culture [25% to 50% of cases])

Decreased in

Condition/Test Showing Decreased Result

- Abdominal malignancy (glucose)
- Tuberculous effusion (glucose)

CRITICAL FINDINGS

Positive culture findings in any sterile body fluid.

Note and immediately report to the health-care provider (HCP) positive culture results, if ordered, and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is

a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Bloody fluids may result from a traumatic tap.
- Unknown hyperglycemia or hypoglycemia may be misleading in the comparison of fluid and serum glucose levels. Therefore, it is advisable to collect comparative serum samples a few hours before performing paracentesis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist with evaluation of fluid surrounding the abdominal organs.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's gastrointestinal and immune system, especially any bleeding disorders and

other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Note any recent procedures that can interfere with test results.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. If patient has ascites, obtain weight and measure abdominal girth. Inform the patient that it may be necessary to remove hair from the site before the procedure. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the abdomen wall. Explain that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the anesthetic injection may cause an initial stinging sensation. Explain that after the skin has been anesthetized, a large needle will be inserted through the abdominal wall and a “popping” sensation may be experienced as the needle penetrates the peritoneum. Inform the patient that specimen collection is performed under sterile conditions by an HCP specializing in this procedure and usually takes approximately 30 min to complete.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction. The requesting HCP may request that anticoagulants and aspirin be withheld.

The number of days to withhold medication is dependent on the type of anticoagulant.

- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Bleeding, infection, puncture of surrounding vessels or organs

- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Notify the HCP if patient anticoagulant therapy has not been withheld.
- ▶ Have emergency equipment readily available.
- ▶ Have the patient void, or catheterize the patient to avoid accidental puncture of the bladder if he or she is unable to void.
- ▶ Have the patient remove clothing and change into a gown for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV line to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- ▶ Assist the patient to a comfortable seated position with feet and back supported or in high Fowler's position.
- ▶ Clip hair from the site as needed, cleanse the site with an antiseptic solution, and drape the area with sterile towels prior to the administration of

local anesthesia. The skin at the injection site is then anesthetized.

- ▶ The paracentesis needle is inserted 1 to 2 in. below the umbilicus, and fluid is removed. If lavage fluid is required (helpful if malignancy is suspected), saline or Ringer's lactate can be infused via the needle over a 15- to 20-min period before the lavage fluid is removed. Monitor vital signs every 15 min for signs of hypovolemia or shock.
- ▶ No more than 1,500 to 2,000 mL of fluid should be removed at a time, even in the case of a therapeutic paracentesis, because of the risk of hypovolemia and shock.
- ▶ The needle is withdrawn, and slight pressure is applied to the site. Apply a sterile dressing to the site.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place samples in properly labeled specimen containers, and promptly transport the specimens to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ Monitor vital signs every 15 min for the first hr, every 30 min for the next 2 hr, every hour for the next 4 hr, and every 4 hr for the next 24 hr. Take the patient's temperature every 4 hr for 24 hr. Monitor intake and output for 24 hr. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe/assess the puncture site for bleeding or drainage and signs of inflammation each time vital signs are taken and daily thereafter for several days. Report to the HCP if bleeding is present.
- ▶ Obtain weight and measure abdominal girth if a large amount of fluid was removed.

- ▶ Inform the patient that 1 hr or more of bed rest is required after the procedure.
- ▶ Instruct the patient to immediately report severe abdominal pain. (Note: Rigidity of abdominal muscles indicates developing peritonitis.) Report to HCP if abdominal rigidity or pain is present.
- ▶ Observe/assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.
- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, if appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include cancer antigens, CBC, CBC WBC count and differential, CT abdomen, CT biliary tract and liver, culture and smear mycobacteria, culture blood, culture fungal, culture viral, KUB studies, laparoscopy abdominal, liver and spleen scan, MRI abdomen, US abdomen, and US spleen.
- ▶ Refer to the Gastrointestinal and Immune systems tables at the end of the book for related tests by body system.

Phosphorus, Blood

SYNONYM/ACRONYM: Inorganic phosphorus, phosphate, PO_4 .

COMMON USE: To assist in evaluating multiple body system functions by monitoring phosphorus levels in relation to other electrolytes. Used specifically to evaluate renal function in at-risk patients.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Spectrophotometry)

Age	Conventional Units	SI Units (Conventional Units \times 0.323)
0–5 day	4.6–8 mg/dL	1.5–2.6 mmol/L
1–3 yr	3.9–6.5 mg/dL	1.3–2.1 mmol/L
4–6 yr	4–5.4 mg/dL	1.3–1.7 mmol/L
7–11 yr	3.7–5.6 mg/dL	1.2–1.8 mmol/L
12–13 yr	3.3–5.4 mg/dL	1.1–1.7 mmol/L
14–15 yr	2.9–5.4 mg/dL	0.9–1.7 mmol/L
16–19 yr	2.8–4.6 mg/dL	0.9–1.5 mmol/L
Adult	2.5–4.5 mg/dL	0.8–1.4 mmol/L

Values may be slightly decreased in older adults due to dietary insufficiency or the effects of medications and the presence of multiple chronic or acute diseases with or without muted symptoms.

DESCRIPTION: Phosphorus, in the form of phosphate, is distributed throughout the body. Approximately 85% of the body's phosphorus is stored in bones; the remainder is found in cells and body fluids. It is the major intracellular anion and plays a crucial role in cellular metabolism, maintenance of cellular membranes, and formation of bones and teeth. Phosphorus also indirectly affects the release of oxygen from hemoglobin by affecting the formation of 2,3-bisphosphoglycerate. The reabsorption and excretion of phosphorus is largely regulated by the parathyroid glands and the kidneys. Levels of phosphorus are

also affected by dietary intake and are dependent on the presence of activated vitamin D for absorption by the intestines. Calcium and phosphorus are interrelated with respect to absorption and metabolic function. They have an inverse relationship with respect to concentration; serum phosphorus is increased when serum calcium is decreased.

Hyperphosphatemia can result in an infant fed only cow's milk during the first few weeks of life because of the combination of a high phosphorus content in cow's milk and the inability of infants' kidneys to clear the excess phosphorus.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in establishing a diagnosis of hyperparathyroidism
- Assist in the evaluation of renal failure

POTENTIAL DIAGNOSIS

Increased in

- Acromegaly (*related to increased renal absorption*)
- Bone metastases (*related to release from bone stores*)
- Diabetic ketoacidosis (*acid-base imbalance causes intracellular phosphorus to move into the extracellular fluid*)
- Excessive levels of vitamin D (*vitamin D promotes intestinal absorption of phosphorus; excessive levels promote phosphorus release from bone stores*)
- Hyperthermia (*tissue damage causes intracellular phosphorus to be released into circulation*)
- Hypocalcemia (*calcium and phosphorus have an inverse relationship*)
- Hypoparathyroidism (*related to increased renal absorption*)
- Lactic acidosis (*acid-base imbalance causes intracellular phosphorus to move into the extracellular fluid*)
- Milk alkali syndrome (*increased dietary intake*)
- Pseudohypoparathyroidism (*related to increased renal absorption*)
- Pulmonary embolism (*related to respiratory acid-base imbalance and compensatory mechanisms*)
- Renal failure (*related to decreased renal excretion*)
- Respiratory acidosis (*acid-base imbalance causes intracellular phosphorus to move into the extracellular fluid*)

Decreased in

- Acute gout (*related to decreased circulating calcium in calcium crystal-induced gout; calcium*

and phosphorus have an inverse relationship)

- Alcohol withdrawal (*related to malnutrition*)
- Gram-negative bacterial septicemia
- Growth hormone deficiency
- Hyperalimentation therapy
- Hypercalcemia (*calcium and phosphorus have an inverse relationship*)
- Hyperinsulinism (*insulin increases intracellular movement of phosphorus*)
- Hyperparathyroidism (*parathyroid hormone [PTH] increases renal excretion*)
- Hypokalemia
- Impaired renal absorption (*decreases return of phosphorus to general circulation*)
- Malabsorption syndromes (*related to insufficient intestinal absorption of phosphorus*)
- Malnutrition (*related to deficient intake*)
- Osteomalacia (*evidenced by hypophosphatemia*)
- PTH-producing tumors (*PTH increases renal excretion*)
- Primary hyperparathyroidism (*PTH increases renal excretion*)
- Renal tubular acidosis
- Renal tubular defects (*related to decreased renal absorption*)
- Respiratory alkalosis
- Respiratory infections
- Rickets (*related to vitamin D deficiency*)
- Salicylate poisoning
- Severe burns
- Severe vomiting and diarrhea (*related to excessive loss*)
- Vitamin D deficiency (*related to vitamin D deficiency, which reduces intestinal and renal tubular absorption of phosphorus*)

CRITICAL FINDINGS

Adults

- Less than 1.0 mg/dL (SI: Less than 0.3 mmol/L)

- Greater than 8.9 mg/dL (SI: Greater than 2.9 mmol/L)

Children

- Less than 1.3 mg/dL (SI: Less than 0.4 mmol/L)
- Greater than 8.9 mg/dL (SI: Greater than 2.9 mmol/L)

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Interventions including IV replacement therapy with sodium or potassium phosphate may be necessary. Close monitoring of both phosphorus and calcium is important during replacement therapy.

INTERFERING FACTORS

- Drugs that may increase phosphorus levels include anabolic steroids, β -adrenergic blockers, ergocalciferol, furosemide, hydrochlorothiazide,

methicillin (occurs with nephrotoxicity), oral contraceptives, parathyroid extract, phosphates, sodium etidronate, tetracycline (occurs with nephrotoxicity), and vitamin D.

- Drugs that may decrease phosphorus levels include acetazolamide, albuterol, aluminum salts, amino acids (via IV hyperalimentation), anesthetic agents, anticonvulsants, calcitonin, epinephrine, fibrin hydrolysate, fructose, glucocorticoids, glucose, insulin, mannitol, oral contraceptives, pamidronate, phenothiazine, phytate, and plicamycin.
- Serum phosphorus levels are subject to diurnal variation: They are highest in late morning and lowest in the evening; therefore, serial samples should be collected at the same time of day for consistency in interpretation.
- Hemolysis will falsely increase phosphorus values.
- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, thereby falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest if it is present in the IV solution, thereby falsely increasing the result.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in a general evaluation of body systems.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine, gastrointestinal, genitourinary, and musculoskeletal systems;

symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Severe hypophosphatemia is common in elderly patients or patients who have been hospitalized for long periods of time.

Good dietary sources of phosphorus include meat, dairy products, nuts, and legumes. To decrease phosphorus levels to normal in the patient with hyperphosphatemia, dietary restriction may be recommended. Other interventions may include the administration of phosphate binders or calcitriol (the activated form of vitamin D).

- ▶ **Nutritional Considerations:** Vitamin D is necessary for the body to absorb phosphorus. Educate the patient with vitamin D deficiency, as appropriate, that the main dietary sources of vitamin D are cod liver oil and fortified dairy foods such as milk, cheese, and orange juice. Explain to the patient that vitamin D is also synthesized by the body, in the skin, and is activated by sunlight.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family. Educate the patient regarding access to nutritional counseling services. Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone, blood gases, BUN, calcitonin, calcium, calculus kidney stone panel, carbon dioxide, chloride, collagen cross-linked N-telopeptides, CBC WBC count and differential, creatinine, fecal analysis, fecal fat, FDP, glucagon, glucose, GH, insulin, lactic acid, lung perfusion scan, lung ventilation scan, osmolality, osteocalcin, PTH, parathyroid scan, phosphorus urine, potassium, US abdomen, and vitamin D.
- ▶ Refer to the Endocrine, Gastrointestinal, Genitourinary, and Musculoskeletal systems tables at the end of the book for related tests by body system.

Phosphorus, Urine

SYNONYM/ACRONYM: Urine phosphate.

COMMON USE: To assist in evaluating calcium and phosphorus levels related to use of diuretics in progression of renal disease.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Spectrophotometry) Reference values are dependent on phosphorus and calcium intake. Phosphate excretion exhibits diurnal variation and is significantly higher at night.

Conventional Units

400–1,300 mg/24 hr

SI Units (Conventional Units × 0.0323)

12.9–42 mmol/24 hr

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Abuse of diuretics (*related to increased renal excretion*)
- Primary hyperparathyroidism (*parathyroid hormone [PTH] increases renal excretion*)
- Renal tubular acidosis
- Vitamin D deficiency (*related to decreased renal reabsorption*)

Decreased in

- Hypoparathyroidism (*PTH enhances renal excretion; therefore, a lack of PTH will decrease urine phosphorus levels*)
- Pseudohypoparathyroidism (*PTH enhances renal reabsorption; therefore, a lack of response to PTH, as in pseudohypoparathyroidism, will decrease urine phosphorus levels*)
- Vitamin D intoxication (*vitamin D promotes renal excretion of phosphorus*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Plasminogen

SYNONYM/ACRONYM: Profibrinolysin, PMG.

COMMON USE: To assess thrombolytic disorders such as disseminated intravascular coagulation (DIC) and monitor thrombolytic therapy.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Chromogenic substrate for plasminogen activity and nephelometric for plasminogen antigen)

Plasminogen activity	80–100% of normal
Plasminogen antigen	7.5–15.5 mg/dL

Plasminogen activity in newborns is half of adult ranges.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Pregnancy (late) (*pathophysiology is unclear*)

Decreased in

- DIC (*related to increased consumption during the hyperfibrinolytic state by conversion to plasmin*)
- Fibrinolytic therapy with tissue plasminogen activators such as

streptokinase or urokinase (*related to increased consumption by conversion to plasmin*)

- Hereditary deficiency
- Liver disease (*related to decreased production by damaged liver cells*)
- Neonatal hyaline membrane disease (*possibly related to deficiency of plasminogen*)
- Postsurgical period (*possibly related to trauma of surgery*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Platelet Antibodies

SYNONYM/ACRONYM: Antiplatelet antibody; platelet-bound IgG/IgM, direct and indirect.

COMMON USE: To assess for the presence of platelet antibodies to assist in diagnosing thrombocytopenia related to autoimmune conditions and platelet transfusion compatibility issues.

SPECIMEN: Serum (1 mL) collected in a red-top tube for indirect immunoglobulin G (IgG) antibody. Whole blood (7 mL) collected in a lavender (EDTA)-, yellow (ACD)-, or pink (K2EDTA)-top tube for direct antibody.

NORMAL FINDINGS: (Method: Solid-phase enzyme-linked immunoassay) Negative.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Development of platelet antibodies is associated with autoimmune conditions and medications.

- AIDS (*related to medications used therapeutically*)
- Acute myeloid leukemia (*related to medications used therapeutically*)
- Idiopathic thrombocytopenic purpura (*related to development of platelet-associated IgG antibodies*)
- Immune complex diseases
- Multiple blood transfusions (*related in most cases to sensitization to PLAI antigens on donor red blood*

cells that will stimulate formation of antiplatelet antibodies)

- Multiple myeloma (*related to medications used therapeutically*)
- Neonatal immune thrombocytopenia (*related to maternal platelet-associated antibodies directed against fetal platelets*)
- Paroxysmal hemoglobinuria
- Rheumatoid arthritis (*related to medications used therapeutically*)
- Systemic lupus erythematosus (*related to medications used therapeutically*)
- Thrombocytopenias provoked by drugs (see monograph titled “Complete Blood Count, Platelet Count”)

Decreased in: N/A

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Plethysmography

SYNONYM/ACRONYM: Impedance plethysmography, PVR.

COMMON USE: To measure changes in blood vessel size or changes in gas volume in the lungs to assist in diagnosing diseases such as deep vein thrombosis (DVT), chronic obstructive pulmonary disease (COPD), and some peripheral vascular disorders.

AREA OF APPLICATION: Veins, arteries, and lungs.

CONTRAST: None.

DESCRIPTION: Plethysmography is a noninvasive diagnostic manometric study used to measure changes in the size of blood vessels by determining volume changes in the blood vessels of

the eye, extremities, and neck or to measure gas volume changes in the lungs.

Arterial plethysmography assesses arterial circulation in an upper or lower limb; it is used to

diagnose extremity arteriosclerotic disease and to rule out occlusive disease. The test requires a normal extremity for comparison of results. The test is performed by applying a series of three blood pressure cuffs to the extremity. The amplitude of each pulse wave is then recorded.

Venous plethysmography, done with a series of cuffs, measures changes in venous capacity and outflow (volume and rate of outflow); it is used to diagnose a thrombotic condition that causes obstruction of the major veins of the extremity. When the cuffs are applied to an extremity in patients with venous obstruction, no initial increase in leg volume is recorded because the venous volume of the leg cannot dissipate quickly.

Body plethysmography measures the total amount (volume) of air within the thorax, whether or not the air is in ventilatory communication with the lung; the elasticity (compliance) of the lungs; and the resistance to airflow in the respiratory tree. It is used in conjunction with pulmonary stress testing and pulmonary function testing.

Impedance plethysmography is widely used to detect acute deep vein thrombosis (DVT) of the leg, but it can also be used in the arm, abdomen, neck, or thorax. Doppler flow studies now are used to identify DVT, but ultrasound studies are less accurate in examinations below the knee.

This procedure is contraindicated for: N/A

INDICATIONS

Arterial Plethysmography

- Confirm suspected acute arterial embolization
- Detect vascular changes associated with Raynaud's phenomenon and disease
- Determine changes in toe or finger pressures when ankle pressures are elevated as a result of arterial calcifications
- Determine the effect of trauma on the arteries in an extremity
- Determine peripheral small-artery changes (ischemia) caused by diabetes, and differentiate these changes from neuropathy
- Evaluate suspected arterial occlusive disease
- Locate and determine the degree of arterial atherosclerotic obstruction and vessel patency in peripheral atherosclerotic disease, as well as inflammatory changes causing obliteration in the vessels in thromboangiitis obliterans

Venous Plethysmography

- Detect partial or total venous thrombotic obstruction
- Determine valve competency in conjunction with Doppler ultrasonography in the diagnosis of varicose veins

Body Plethysmography

- Detect acute pulmonary disorders, such as atelectasis
- Detect or determine the status of chronic obstructive pulmonary disease (COPD), such as emphysema, asthma, or chronic bronchitis
- Detect or determine the status of restrictive pulmonary disease, such as fibrosis
- Detect infectious pulmonary diseases, such as pneumonia
- Determine baseline pulmonary status before pulmonary rehabilitation

to determine potential therapeutic benefit

- Differentiate between obstructive and restrictive pulmonary pathology

Impedance Plethysmography

- Act as a diagnostic screen for patients at risk for DVT
- Detect and evaluate DVT
- Evaluate degree of resolution of DVT after treatment
- Evaluate patients with suspected pulmonary embolism (most pulmonary emboli are complications of DVT in the leg)

POTENTIAL DIAGNOSIS

Normal findings in

- Arterial plethysmography:
 - Normal arterial pulse waves:** Steep upslope, more gradual downslope with narrow pointed peaks
 - Normal pressure:** Less than 20 mm Hg systolic difference between the lower and upper extremities; toe pressure greater than or equal to 80% of ankle pressure and finger pressure greater than or equal to 80% of wrist pressure
- Venous plethysmography:
 - Normal venous blood flow in the extremities
 - Venous filling times greater than 20 sec
- Body plethysmography:
 - Thoracic gas volume:** 2,400 mL
 - Compliance:** 0.2 L/cm H₂O
 - Airway resistance:** 0.6 to 2.5 cm H₂O/L per sec
- Impedance plethysmography:
 - Sharp rise in volume with temporary occlusion
 - Rapid venous outflow with release of the occlusion

Abnormal findings in

- COPD, restrictive lung disease, lung infection, or atelectasis (body plethysmography)
- DVT (arterial, venous, or impedance plethysmography)
- Incompetent valves, thrombosis, or thrombotic obstruction in a major vein in an extremity

- Small-vessel diabetic changes
- Vascular disease (Raynaud's phenomenon)
- Vascular trauma

CRITICAL FINDINGS

- DVT

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Arterial Plethysmography

Factors that may impair the results of the examination

- Cigarette smoking 2 hr before the study, which causes inaccurate results because the nicotine constricts the arteries.
- Alcohol consumption.
- Low cardiac output.
- Shock.
- Compression of pelvic veins (tumors or external compression by dressings).

- Environmental temperatures (hot or cold).
- Arterial occlusion proximal to the extremity to be examined, which can prevent blood flow to the limb.

Venous Plethysmography

Factors that may impair the results of the examination

- Low environmental temperature or cold extremity, which constricts the vessels.
- High anxiety level or muscle tenseness.
- Venous thrombotic occlusion proximal to the extremity to be examined, which can affect blood flow to the limb.

Body Plethysmography

Factors that may impair the results of the examination

- Inability of the patient to follow breathing instructions during the procedure.

Impedance Plethysmography

Factors that may impair the results of the examination

- Movement of the extremity during electrical impedance recording, poor electrode contact, or nonlinear electrical output, which can cause false-positive results.
- Constricting clothing or bandages.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▮ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▮ **Patient Teaching:** Inform the patient this procedure can assist in evaluating blood vessel size and lung ventilation.
- ▮ Obtain a history of the patient's complaints, including a list of known

allergens, especially allergies or sensitivities to latex.

- ▮ Obtain a history of the patient's cardiovascular and pulmonary systems, symptoms, and results of laboratory tests and diagnostic and surgical procedures.
- ▮ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▮ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▮ Review the procedure with the patient. Address concerns about pain related to the procedure and explain to the patient that no discomfort will be experienced during the test. Explain that there may be some discomfort during insertion of the nasoesophageal catheter if compliance testing is done. Inform the patient that the procedure is generally performed in a specialized area or at the bedside by an HCP who specializes in this procedure, with support staff, and usually takes 30 to 60 min.
- ▮ Assess the patient's ability to comply with directions given for rest, positioning, and activity before and during the procedure.
- ▮ For body plethysmography, record the patient's weight, height, and gender. Determine whether the patient is claustrophobic.
- ▮ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▮ Instruct the patient to refrain from smoking for 2 hr prior to the procedure.
- ▮ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▮ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▮ Ensure the patient has refrained from smoking for 2 hr before the procedure.
- ▮ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.

- ▶ Obtain and record baseline vital signs.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to report any unexpected symptoms that occur during the test.

Arterial Plethysmography

- ▶ Explain to the patient that cuffs are applied to the extremity to measure and compare blood flow.
- ▶ Place the patient in a semi-Fowler's position on an examination table or in bed.
- ▶ Ask the patient to notify medical personnel if he or she has unexpected symptoms during the test.
- ▶ Instruct the patient to remain still during the procedure.
- ▶ Apply three blood pressure cuffs to the extremity and attach a pulse volume recorder (plethysmograph), which records the amplitude of each pulse wave.
- ▶ Inflate the cuffs to 65 mm Hg to measure the pulse waves of each cuff. When compared with a normal limb, these measurements determine the presence of arterial occlusive disease.

Venous Plethysmography

- ▶ Explain to the patient that cuffs are applied to the extremity to measure and compare blood flow.
- ▶ Place the patient in a semi-Fowler position on an examination table or in bed.
- ▶ Instruct the patient to remain still during the procedure.
- ▶ Apply two blood pressure cuffs to the extremity, one on the proximal part of the extremity (occlusion cuff) and the other on the distal part of the extremity (recorder cuff). Attach a third cuff to the pulse volume recorder.
- ▶ Inflate the recorder cuff to 10 mm Hg, and evaluate the effects of respiration on venous volume: Absence of changes during respirations indicates venous thrombotic occlusion.
- ▶ Inflate the occlusion cuff to 50 mm Hg, and record venous volume on the pulse monitor. Deflate the occlusion cuff after the highest volume is recorded in the recorder cuff. A delay in the return to preocclusion volume indicates venous thrombotic occlusion.

Body Plethysmography

- ▶ Place the patient in a sitting position on a chair in the body box. Explain to the patient that the cuffs are applied to the extremities to measure and compare blood flow.
- ▶ Position a nose clip to prevent breathing through the nose, and connect a mouthpiece to a measuring instrument.
- ▶ Ask the patient to breathe through the mouthpiece.
- ▶ Close the door to the box, and record the start time of the procedure. At the beginning of the study, instruct the patient to pant rapidly and shallowly, without allowing the glottis to close.
- ▶ For compliance testing, a double-lumen nasoesophageal catheter is inserted, and the bag is inflated with air. Intraesophageal pressure is recorded during normal breathing.

Impedance Plethysmography

- ▶ Explain to the patient that cuffs are applied to the extremity to measure and compare blood flow.
- ▶ Place the patient on his or her back with the leg being tested above the heart level.
- ▶ Flex the patient's knee slightly, and rotate the hips by shifting weight to the same side as the leg being tested.
- ▶ Apply conductive gel and electrodes to the legs, near the cuffs.
- ▶ Apply a blood pressure cuff to the thigh.
- ▶ Inflate the pressure cuff attached to the thigh temporarily to occlude venous return without interfering with arterial blood flow. Expect the blood volume in the other calf to increase.
- ▶ A tracing of changes in electrical impedance occurring during inflation and for 15 sec after cuff deflation is recorded.
- ▶ With DVT, blood volume increases less than expected because the veins are already at capacity.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Remove conductive gel and electrodes, as applied.
- ▶ Instruct the patient to resume usual activity and diet, as directed by the HCP.

- ▶ Monitor for severe ischemia, ulcers, and pain of the extremity after arterial, venous, or impedance plethysmography, and handle the extremity gently.
- ▶ Monitor respiratory pattern after body plethysmography, and allow the patient time to resume a normal breathing pattern.
- ▶ Monitor vital signs every 15 min until they return to baseline levels.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in

relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include α_1 -AT, angiography pulmonary, anion gap, arterial/alveolar oxygen ratio, AT-III, biopsy lung, blood gases, bronchoscopy, carboxyhemoglobin, cardiolipin antibodies, chest x-ray, chloride sweat, cold agglutinin, CBC, CBC hemoglobin, CBC WBC count and differential, CT angiography, CT thoracic, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, D-dimer, echocardiography, ECG, EMG, ENG, fibrinogen, gram stain, IgE, lactic acid, lung perfusion scan, lung ventilation scan, lupus anticoagulant antibodies, MR angiography, MRI chest, MRI venography, osmolality, phosphorus, plasminogen, pleural fluid analysis, potassium, PET chest, PFT, pulse oximetry, sodium, TB skin test, and US arterial and venous Doppler of the extremities.
- ▶ Refer to the Cardiovascular and Pulmonary systems tables at the end of the book for related tests by body system.

Pleural Fluid Analysis

SYNONYM/ACRONYM: Thoracentesis fluid analysis.

COMMON USE: To assess and categorize fluid obtained from within the pleural space for infection, cancer, and blood as well as identify the cause of its accumulation.

SPECIMEN: Pleural fluid (5 mL) collected in a green-top (heparin) tube for amylase, cholesterol, glucose, lactate dehydrogenase (LDH), pH, protein, and triglycerides; lavender-top (EDTA) tube for cell count; sterile containers for microbiology specimens; 200 to 500 mL of fluid in a clear container with anticoagulant for cytology. Ensure that there is an equal amount of fixative and fluid in the container for cytology.

NORMAL FINDINGS: (Method: Spectrophotometry for amylase, cholesterol, glucose, LDH, protein, and triglycerides; ion-selective electrode for pH; automated or manual cell count; macroscopic and microscopic examination of cultured microorganisms; microscopic examination of specimen for microbiology and cytology)

Appearance	Clear
Color	Pale yellow
Amylase	Parallels serum values
Cholesterol	Parallels serum values
CEA	Parallels serum values
Glucose	Parallels serum values
LDH	Less than 200 units/L
Fluid LDH-to-serum LDH ratio	0.6 or less
Protein	3 g/dL
Fluid protein-to-serum protein ratio	0.5 or less
Triglycerides	Parallel serum values
pH	7.37–7.43
RBC count	None seen
WBC count	Less than 1,000/microL
Culture	No growth
Gram stain	No organisms seen
Cytology	No abnormal cells seen

CEA = carcinoembryonic antigen; LDH = lactate dehydrogenase; RBC = red blood cell; WBC = white blood cell.

DESCRIPTION: The pleural cavity and organs within it are lined with a protective membrane. The fluid between the membranes is called *serous fluid*. Normally, only a small amount of fluid is present because the rates of fluid production and absorption are about the same. Many abnormal conditions can result in the buildup of fluid within the pleural cavity. Specific tests are usually ordered in addition to a common battery of tests

used to distinguish a transudate from an exudate. *Transudates* are effusions that form as a result of a systemic disorder that disrupts the regulation of fluid balance, such as a suspected perforation. *Exudates* are caused by conditions involving the tissue of the membrane itself, such as an infection or malignancy. Fluid is withdrawn from the pleural cavity by needle aspiration and tested as listed in the previous and following tables.

Characteristic	Transudate	Exudate
Appearance	Clear	Cloudy or turbid
Specific gravity	Less than 1.015	Greater than 1.015
Total protein	Less than 2.5 g/dL	Greater than 3 g/dL
Fluid protein-to-serum protein ratio	Less than 0.5	Greater than 0.5
LDH	Parallels serum value	Less than 200 units/L
Fluid LDH-to-serum LDH ratio	Less than 0.6	Greater than 0.6
Fluid cholesterol	Less than 55 mg/dL	Greater than 55 mg/dL
WBC count	Less than 100/microL	Greater than 1,000/microL

LDH = lactate dehydrogenase; WBC = white blood cell.

This procedure is contraindicated for: N/A

INDICATIONS

- Differentiate transudates from exudates
- Evaluate effusion of unknown cause
- Investigate suspected rupture, immune disease, malignancy, or infection

POTENTIAL DIAGNOSIS

- *Bacterial or tuberculous empyema:* Elevated white blood cell (WBC) count with a predominance of neutrophils, increased fluid protein-to-serum protein ratio, increased fluid LDH-to-serum LDH ratio, decreased glucose, pH less than 7.3
- *Chylous pleural effusion:* Marked increase in both triglycerides (two to three times serum level) and chylomicrons
- *Effusion caused by pneumonia:* Elevated WBC count with a predominance of neutrophils and some eosinophils, increased fluid protein-to-serum protein ratio, increased fluid LDH-to-serum LDH ratio, pH less than 7.4 (and decreased glucose if bacterial pneumonia)
- *Esophageal rupture:* Significantly decreased pH (6.0) and elevated amylase
- *Hemothorax:* Bloody appearance, increased RBC count, elevated hematocrit
- *Malignancy:* Elevated WBC count with a predominance of lymphocytes, possible elevated RBC count, abnormal cytology, increased fluid protein-to-serum protein ratio, increased fluid LDH-to-serum LDH ratio, decreased glucose, pH less than 7.3
- *Pancreatitis:* Elevated WBC count with a predominance of neutrophils, elevated RBC count, pH greater than 7.3, increased fluid protein-to-serum protein ratio,

increased fluid LDH-to-serum LDH ratio, increased amylase

- *Pulmonary infarction:* Elevated RBC count, elevated WBC count with a predominance of neutrophils, pH greater than 7.3, normal glucose, increased fluid protein-to-serum protein ratio, and increased fluid LDH-to-serum LDH ratio.
- *Pulmonary tuberculosis:* Elevated WBC count with a predominance of lymphocytes, positive acid-fast bacillus stain and culture, increased protein, decreased glucose, pH less than 7.3
- *Rheumatoid disease:* Elevated WBC count with a predominance of either lymphocytes or neutrophils, pH less than 7.3, decreased glucose, increased fluid protein-to-serum protein ratio, increased fluid LDH-to-serum LDH ratio, increased immunoglobulins
- *Systemic lupus erythematosus:* Similar findings as with rheumatoid disease, except that glucose is usually not decreased

CRITICAL FINDINGS

Positive culture findings in any sterile body fluid.

Note and immediately report to the health-care provider (HCP) positive culture results, if ordered, and related symptoms. pH 7.1 to 7.2 indicates need for immediate drainage.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP,

Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

- Bloody fluids may be the result of a traumatic tap.
- Unknown hyperglycemia or hypoglycemia may be misleading in the comparison of fluid and serum glucose levels. Therefore, it is advisable to collect comparative serum samples a few hours before performing thoracentesis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in identifying the type of fluid being produced within the body cavity.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and respiratory systems, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.

- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure.
- ▶ Review the procedure with the patient. Inform the patient that it may be necessary to remove hair from the site before the procedure. Discuss with the patient that the requesting HCP may request that a cough suppressant be given before the thoracentesis. Address concerns about pain and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to needle insertion through the chest wall into the pleural space. Explain that any discomfort with the needle insertion will be minimized with local anesthetics and systemic analgesics. Explain that the local anesthetic injection may cause an initial stinging sensation. Meperidine (Demerol) or morphine may be given as a sedative. Inform the patient that the needle insertion is performed under sterile conditions by an HCP specializing in this procedure. The procedure usually takes about 20 min to complete.
- ▶ Explain that an IV line will be inserted to allow infusion of IV fluids, antibiotics, anesthetics, and analgesics.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction. The requesting HCP may request that anticoagulants and aspirin be withheld. The number of days to withhold medication is dependent on the type of anticoagulant.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:**Potential Complications:**

- Pneumothorax, bleeding, hemoptysis, and pulmonary edema.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Notify the HCP if patient anticoagulant therapy has not been withheld.
- ▶ Have emergency equipment readily available. Keep resuscitation equipment on hand in the case of respiratory impairment or laryngospasm after the procedure.
- ▶ Avoid using morphine sulfate in those with asthma or other pulmonary disease. This drug can further exacerbate bronchospasms and respiratory impairment.
- ▶ Have the patient remove clothing and change into a gown for the procedure.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement during the local anesthetic and the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date and time of collection, and site location.
- ▶ Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Establish an IV line to allow infusion of IV fluids, anesthetics, analgesics, or IV sedation.
- ▶ Assist the patient into a comfortable sitting or side-lying position.
- ▶ Prior to the administration of local anesthesia, clip hair from the site as needed, cleanse the site with an antiseptic solution, and drape the area with sterile towels. The skin at the injection site is then anesthetized.
- ▶ The thoracentesis needle is inserted, and fluid is removed.
- ▶ The needle is withdrawn, and pressure is applied to the site with a petroleum jelly gauze. A pressure dressing is applied over the petroleum jelly gauze.

- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis).
- ▶ Place samples in properly labeled specimen container, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ Monitor vital signs every 15 min for the first hr, every 30 min for the next 2 hr, every hour for the next 4 hr, and every 4 hr for the next 24 hr. Take the patient's temperature every 4 hr for 24 hr. Monitor intake and output for 24 hr. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe/assess the patient for signs of respiratory distress or skin color changes.
- ▶ Observe/assess the thoracentesis site for bleeding, inflammation, or hematoma formation each time vital signs are taken and daily thereafter for several days.
- ▶ Observe/assess the patient for hemoptysis, difficulty breathing, cough, air hunger, pain, or absent breathing sounds over the affected area. Report to HCP.
- ▶ Inform the patient that 1 hr or more of bed rest (lying on the unaffected side) is required after the procedure. Elevate the patient's head for comfort.
- ▶ Evaluate the patient for symptoms indicating the development of pneumothorax, such as dyspnea, tachypnea, anxiety, decreased breathing sounds, or restlessness. Prepare the patient for a chest x-ray, if ordered, to ensure that a pneumothorax has not occurred as a result of the procedure.
- ▶ Observe/assess for nausea and pain. Administer antiemetic and analgesic medications as needed and as directed by the HCP.
- ▶ Administer antibiotics, as ordered, and instruct the patient in the importance of completing the entire course of antibiotic therapy even if no symptoms are present.

- ▶ Recognize anxiety related to test results, and offer support. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, if appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease

process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antibodies anti-cyclic citrullinated peptide, ANA, biopsy lung, blood gases, cancer antigens, chest x-ray, CBC WBC count and differential, CT thoracic, CRP, culture and smear mycobacteria, culture blood, culture fungal, culture viral, ECG, ESR, MRI chest, and RF.
- ▶ Refer to the Immune and Respiratory systems tables at the end of the book for related tests by body system.

Porphyrins, Urine

SYNONYM/ACRONYM: Coproporphyrin, porphobilinogen, urobilinogen, and other porphyrins.

COMMON USE: To assess for porphyrias in the urine to assist with diagnosis of genetic disorders associated with porphyrin synthesis as well as heavy metal toxicity.

SPECIMEN: Urine (10 mL) from a random or timed specimen collected in a clean, amber-colored plastic collection container with sodium carbonate as a preservative.

NORMAL FINDINGS: (Method: High-performance liquid chromatography for porphyrins; spectrophotometry for δ -aminolevulinic acid and porphobilinogen)

Test	Conventional Units	SI Units
Coproporphyrin I	0–24 mcg/24 hr	0–36.7 nmol/24 hr
Coproporphyrin III	0–74 mcg/24 hr	0–113.2 nmol/24 hr
Uroporphyrins	0–24 mcg/24 hr	0–34.3 nmol/24 hr
Hexacarboxylporphyrin	Less than 1 mcg/24 hr	Less than 1.34 nmol/24 hr
Heptacarboxylporphyrin	Less than 4 mcg/24 hr	Less than 5.1 nmol/24 hr

(Conventional Units × 1.53)

(Conventional Units × 1.43)

(Conventional Units × 1.34)

(Conventional Units × 1.27)

Test	Conventional Units	SI Units
Porphobilinogen	Less than 2 mg/24 hr	(Conventional Units \times 4.42) Less than 8.8 micromol/24 hr
δ -Aminolevulinic acid	1.5–7.5 mg/24 hr	(Conventional Units \times 7.626) 11.4–57.2 micromol/24 hr

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Accumulation of porphyrins or porphyrin precursors in the body is common to the various types of porphyrias. Excessive amounts of circulating porphyrins and precursors are excreted in the urine.

- Acute intermittent porphyria (*related to an autosomal dominant disorder resulting in a deficiency of the enzyme porphobilinogen deaminase and increased excretion of porphobilinogen and delta-aminolevulinic acid [δ -ALA] in the urine*)
- Acquired or chemical porphyrias (heavy metal, benzene, or carbon tetrachloride toxicity; drug induced) (*related to a disturbance in the heme biosynthetic pathway and increased excretion of delta-aminolevulinic acid in the urine*)
- ALAD deficiency porphyria (*related to an autosomal recessive disorder resulting in a deficiency of the enzyme delta-aminolevulinic acid dehydratase and increased excretion of δ -ALA in the urine*)
- Hepatoerythropoietic porphyria (*related to an autosomal recessive disorder resulting*

in a deficiency of the enzyme uroporphyrinogen decarboxylase and increased excretion of uroporphyrin and heptacarboxylporphyrin in the urine)

- Hereditary coproporphyria (*related to an autosomal dominant disorder resulting in a deficiency of the enzyme coproporphyrinogen oxidase and increased excretion of porphobilinogen, δ -ALA, and coproporphyrin in the urine*)
- Porphyria cutanea tarda (*related to an acquired deficiency of the enzyme uroporphyrinogen decarboxylase activated by exposure to triggers such as iron, alcohol, hepatitis C virus, HIV, or estrogens and increased excretion of uroporphyrin, heptacarboxylporphyrin, and coproporphyrin in the urine*)
- Variegate porphyrias (*related to an autosomal dominant disorder resulting in a deficiency of the enzyme protoporphyrinogen oxidase and increased excretion of porphobilinogen, coproporphyrin, and δ -ALA in the urine during attacks; excretion of normal levels may be found between attacks*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

Positron Emission Tomography, Brain

SYNONYM/ACRONYM: PET scan of the brain.

COMMON USE: To assess blood flow and metabolic processes of the brain to assist in diagnosis of disorders such as ischemic or hemorrhagic stroke or cancer and to evaluate head trauma.

AREA OF APPLICATION: Brain.

CONTRAST: IV radioactive material (fluorodeoxyglucose [FDG]).

DESCRIPTION: Positron emission tomography (PET) combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. After the radionuclide becomes concentrated in the brain, PET images of blood flow or metabolic processes at the cellular level can be obtained. Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in neurological conditions can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states. The brain uses oxygen and glucose almost exclusively to meet its energy needs, and therefore the brain's metabolism has been studied widely with PET.

The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron

located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be detected by the scanner. This information is transmitted to the computer, which determines the location and its distribution and translates the emissions as color-coded images for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis. Each radionuclide tracer is designed to measure a specific body process, such as glucose metabolism, blood flow, or brain tissue perfusion. The radionuclide can be administered IV or inhaled as a gas. PET has had the greatest clinical impact in patients with epilepsy, dementia, neurodegenerative diseases, inflammation, cerebrovascular disease (indirectly), and brain tumors.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography (SPECT).

Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Detect Parkinson's disease and Huntington's disease, as evidenced by decreased metabolism
- Determine the effectiveness of therapy, as evidenced by biochemical activity of normal and abnormal tissues
- Determine physiological changes in psychosis and schizophrenia
- Differentiate between tumor recurrence and radiation necrosis
- Evaluate Alzheimer's disease and differentiate it from other causes of dementia, as evidenced by decreased cerebral flow and metabolism
- Evaluate cranial tumors pre- and post-operatively and determine stage and appropriate treatment or procedure
- Identify cerebrovascular accident or aneurysm, as evidenced by decreased blood flow and oxygen use
- Identify focal seizures, as evidenced by decreased metabolism between seizures

POTENTIAL DIAGNOSIS

Normal findings in

- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution

Abnormal findings in

- Alzheimer's disease
- Aneurysm
- Cerebral metastases

- Cerebrovascular accident
- Creutzfeldt-Jakob disease
- Dementia
- Head trauma
- Huntington's disease
- Migraine
- Parkinson's disease
- Schizophrenia
- Seizure disorders
- Tumors

CRITICAL FINDINGS

- Aneurysm
- Cerebrovascular accident
- Tumor with significant mass effect

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

- Drugs that alter glucose metabolism, such as tranquilizers or insulin, because hypoglycemia can alter PET results.
- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hr before the study, because the effects of these substances would make it difficult to evaluate the patient's true physiological state (e.g., alcohol is a vasoconstrictor and would decrease blood flow to the target organ).
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- False-positive findings may occur as a result of normal gastrointestinal tract uptake and uptake in areas of infection or inflammation.
- Consultation with a HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear

badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that this procedure can assist in assessing blood flow to the brain and brain tissue metabolism.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology suite, by an HCP specializing in this procedure, with support staff, and takes approximately 60 to 120 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Sometimes FDG examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to avoid taking anti-coagulant medication or to reduce dosage as ordered prior to the procedure.
- ▶ Instruct the patient to restrict food for 4 hr; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hr; and withhold medications for 24 hr before the test. Protocols may vary among facilities.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injecting radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; hematoma **related to blood leakage into the tissue following needle insertion**; infection **that might occur if bacteria from the skin surface is introduced at the puncture site**; or nerve injury **that might occur if the needle strikes a nerve**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.

- ▶ Ensure the patient has removed all jewelry and external metallic objects from the area to be examined prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Place the patient in the supine position on an examination table.
- ▶ The radionuclide is injected, and imaging is started after a 30-min delay. If comparative studies are indicated, additional injections may be needed.
- ▶ The patient may be asked to perform different cognitive activities (e.g., reading) to measure changes in brain activity during reasoning or remembering.
- ▶ The patient may be blindfolded or asked to use earplugs to decrease auditory and visual stimuli.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume pretest diet, fluids, medications, or activity.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia,

hyperpnea, hypertension, palpitations, nausea, or vomiting.

- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the injection site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Instruct the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Educate the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ Instruct the patient to flush the toilet immediately after each voiding and to meticulously wash hands with soap and water for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the

radionuclide has been eliminated, about 3 days. Instruct her to express the milk and discard it during the 3-day period to prevent cessation of milk production.

- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include Alzheimer's disease markers, CT brain, EEG, MRI brain, and US arterial Doppler of the carotids.
- ▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

P

Positron Emission Tomography, FDG

SYNONYM/ACRONYM: Fluorodeoxyglucose (FDG)-positron emission tomography (PET).

COMMON USE: To assist in assessment, staging, and monitoring of metabolically active malignant lesions in the breast, abdomen, brain, and heart, such as breast cancer, Parkinson's disease, and Alzheimer's disease.

AREA OF APPLICATION: Abdomen, brain, breast, heart, pelvis.

CONTRAST: IV radioactive material fluorodeoxyglucose (FDG).

DESCRIPTION: Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in neurological conditions can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states. The brain uses oxygen and glucose almost exclusively to meet its energy needs, and therefore the brain's metabolism has been studied widely with positron emission tomography (PET). The role of this procedure is to detect metabolically active malignant lesions. FDG-PET scan may also be used to stage and monitor the response to the malignant disease.

PET combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be detected by the scanner. This information is transmitted to the computer, which determines the location and its distribution and translates the emissions as color-coded images

for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET, even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography. Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Detect Parkinson's disease and Huntington's disease, as evidenced by decreased metabolism
- Determine physiological changes in psychosis and schizophrenia
- Evaluate Alzheimer's disease and differentiate it from other causes of dementia, as evidenced by decreased cerebral flow and metabolism
- Evaluate coronary artery disease (CAD), as evidenced by decreased myocardial blood flow and myocardial perfusion
- Evaluate myocardial viability, as evidenced by low glucose metabolism
- Evaluate tumors preoperatively and postoperatively and determine grade, stage, and appropriate treatment or procedure
- Identify cerebrovascular accident or aneurysm, as evidenced by decreased blood flow and oxygen use

- Identify focal seizures, as evidenced by decreased metabolism between seizures

POTENTIAL DIAGNOSIS

Normal findings in

- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution

Abnormal findings in

- Alzheimer's disease
- Brain trauma
- Breast cancer
- Colorectal cancer
- CAD
- Epilepsy
- Heart muscle dysfunction
- Huntington's disease
- Infections
- Lung cancer
- Lymphoma
- Melanoma
- Metastatic disease
- Myeloma
- Ovarian cancer
- Pancreatic cancer
- Parkinson's disease

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Drugs that alter glucose metabolism, such as tranquilizers, sedatives, or insulin, because hypoglycemia can alter PET results.
- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hr before the study, because the effects of these substances, make it difficult to evaluate the patient's true physiological state (e.g., alcohol is a vasoconstrictor and would decrease blood flow to the target organ).

- Excessive exercise in the preceding 3 days, which can cause factitious uptake of the contrast material in the musculature.
- Excessive anxiety may affect valuation of brain function.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- **Patient Teaching:** Inform the patient this test can assist in assessing blood flow and tissue metabolism.

- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's cardiovascular, hematopoietic, neuromuscular, and reproductive systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain will be experienced during the test, but there may be moments of discomfort. Reassure the patient the radionuclide poses no radioactive hazard and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department, by an HCP specializing in this procedure, with support staff, and takes approximately 1 to 3 hr.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct patients with diabetes to take their pretest dose of insulin at a meal 4 hr before the test.
- ▶ Sometimes FDG examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to restrict food for 4 to 6 hr; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hr; and withhold medications for 24 hr before the test. The exception is that there are no dietary restrictions for patients undergoing cardiac imaging. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.

Establishing an IV site and injecting radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; hematoma **related to blood leakage into the tissue following needle insertion**; infection **that might occur if bacteria from the skin surface is introduced at the puncture site**; or nerve injury **that might occur if the needle strikes a nerve**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations prior to the procedure.
- ▶ Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history

of allergic reactions to any substance or drug.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Cardiac imaging patients may be asked to drink glucose prior to the radionuclide injection.
- ▶ Place the patient in the supine position on an examination table.
- ▶ The radionuclide is injected, and imaging is started after a 30-min delay. Images may be recorded for up to 3 hr postinjection.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
 - ▶ Instruct the patient to resume pretest diet, fluids, medications, and activity.
 - ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
 - ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
 - ▶ Instruct the patient in the care and assessment of the injection site.
 - ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
 - ▶ Instruct the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Educate the patient that radionuclide is eliminated from the body within 6 to 24 hr.
 - ▶ Instruct the patient to flush the toilet immediately after each voiding and to meticulously wash hands with soap and water for 24 hr after the procedure.
 - ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
 - ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated, about 3 days. Instruct her to express the milk and discard it during the 3-day period to prevent cessation of milk production.
 - ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education

include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet.

If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet.

The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry.

A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of breast self-

examination, mammography, magnetic resonance imaging (MRI) of the breast, or other cancer screening procedures should be made after consultation between the patient and HCP. The most current guidelines for breast cancer screening of the general population as well as of individuals with increased risk are available from the American Cancer Society (www.cancer.org), the American College of Obstetricians and Gynecologists (ACOG) (www.acog.org), and the American College of Radiology (www.acr.org). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include AFP, Alzheimer's disease markers, amino acid screen, amylase, barium enema, biopsy breast, biopsy lung, bronchoscopy, calcitonin, cancer antigens, CBC WBC count and differential, CSF analysis, colonoscopy, CT abdomen, CT brain, CT pancreas, CT pelvis, cytology sputum, evoked brain potentials, exercise stress test, fecal analysis, gallium scan, laparoscopy abdominal, laparoscopy gyn, lymphangiogram, mammography, MRI abdomen, MRI brain, MRI breast, MRI pelvis, myocardial perfusion heart scan, peritoneal fluid analysis, PET brain, PET heart, PET pelvis, proctosigmoidoscopy, stereotactic breast biopsy, US breast, US pancreas, US pelvis gyn, and WBC scan.
- ▶ Refer to the Cardiovascular, Musculoskeletal, and Reproductive systems tables at the end of the book for related tests by body system.

Positron Emission Tomography, Heart

SYNONYM/ACRONYM: PET scan of the heart.

COMMON USE: To assess blood flow and metabolic process of the heart to assist in diagnosis of disorders such as coronary artery disease, infarct, and aneurysm.

AREA OF APPLICATION: Heart, chest/thorax, vascular system.

CONTRAST: IV radioactive material (fluorodeoxyglucose [FDG]).

DESCRIPTION: Positron emission tomography (PET) combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. After the radionuclide becomes concentrated in the heart, PET images of blood flow or metabolic processes at the cellular level can be obtained. Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in heart conditions such as myocardial viability can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states.

The positron radiopharmaceuticals generally have short half-lives, ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be

detected by the scanner. This information is transmitted to the computer, which determines the location and its distribution and translates the emissions as color-coded images for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis. Each radionuclide tracer is designed to measure a specific body process, such as glucose metabolism, blood flow, or tissue perfusion. The radionuclide can be administered IV or inhaled as a gas.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET, even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography. Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Assess tissue permeability
- Determine the effects of therapeutic drugs on malfunctioning or diseased tissue
- Determine localization of areas of heart metabolism
- Determine the presence of coronary artery disease (CAD), as evidenced by metabolic state during ischemia and after angina
- Determine the size of heart infarcts
- Identify cerebrovascular accident or aneurysm, as evidenced by decreasing blood flow and oxygen use

POTENTIAL DIAGNOSIS

Normal findings in

- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution

Abnormal findings in

- Chronic obstructive pulmonary disease
- Decreased blood flow and decreased glucose concentration (*indicating necrotic, scarred tissue*)
- Enlarged left ventricle
- Heart chamber disorder
- Myocardial infarction (*indicating increased radionuclide uptake in the myocardium*)
- Pulmonary edema
- Reduced blood flow but increased glucose concentration (*indicating ischemia*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Drugs that alter glucose metabolism, such as tranquilizers or

insulin, because hypoglycemia can alter PET results.

- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hr before the study, because the effects of these substances would make it difficult to evaluate the patient's true physiological state (e.g., alcohol is a vasoconstrictor and would decrease blood flow to the target organ).
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- False-positive findings may occur as a result of normal gastrointestinal tract uptake and uptake in areas of infection or inflammation.

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing blood flow to the heart.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's cardiovascular and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology suite, by an HCP specializing in this procedure, with support staff, and takes approximately 60 to 120 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.

- ▶ Sometimes FDG examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- ▶ Instruct the patient to restrict food for 4 hr; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hr; and withhold medications for 24 hr before the test. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- Establishing an IV site and injecting radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners;** hematoma **related to blood leakage into the tissue following needle insertion;** infection **that might occur if bacteria from the skin surface is introduced at the puncture site;** or nerve injury **that might occur if the needle strikes a nerve.**
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.

- ▶ Ensure the patient has removed all jewelry and external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Place the patient in the supine position on an examination table.
- ▶ The radionuclide is injected and imaging is done at periodic intervals, with continuous scanning done for 1 hr. If comparative studies are indicated, additional injections may be needed.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle site for bleeding, inflammation, or hematoma formation.
- ▶ hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Educate the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ Instruct the patient to flush the toilet immediately after each voiding and to meticulously wash hands with soap and water for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated, about 3 days. Instruct her to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ **Nutritional Considerations:** Abnormal findings may be associated with cardiovascular disease. Nutritional therapy is recommended for the patient identified to be at risk for developing CAD or for individuals who have specific risk factors and/or existing medical conditions (e.g., elevated LDL cholesterol levels, other lipid disorders, insulin-dependent diabetes, insulin resistance, or metabolic syndrome). Other changeable risk factors warranting patient education

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume pretest diet, fluids, medications, and activity.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia,

include strategies to encourage patients, especially those who are overweight and with high blood pressure, to safely decrease sodium intake, achieve a normal weight, ensure regular participation in moderate aerobic physical activity three to four times per week, eliminate tobacco use, and adhere to a heart-healthy diet. If triglycerides also are elevated, the patient should be advised to eliminate or reduce alcohol. The 2013 Guideline on Lifestyle Management to Reduce Cardiovascular Risk published by the American College of Cardiology (ACC) and the American Heart Association (AHA) in conjunction with the National Heart, Lung, and Blood Institute (NHLBI) recommends a “Mediterranean”-style diet rather than a low-fat diet. The new guideline emphasizes inclusion of vegetables, whole grains, fruits, low-fat dairy, nuts, legumes, and nontropical vegetable oils (e.g., olive, canola, peanut, sunflower, flaxseed) along with fish and lean poultry. A similar dietary pattern known as the Dietary Approaches to Stop Hypertension (DASH) diet makes additional recommendations for the reduction of dietary sodium. Both dietary styles emphasize a reduction in consumption of red meats, which are high in saturated fats and cholesterol, and other foods containing sugar, saturated fats, trans fats, and sodium.

- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be

needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests for cardiac indications include anion gap, antiarrhythmic drugs, apolipoprotein A and B, arterial/alveolar oxygen ratio, AST, ANP, α_1 -AT, biopsy lung, blood gases, blood pool imaging, BNP, bronchoscopy, calcium, ionized calcium, carboxyhemoglobin, chest x-ray, chloride sweat, cholesterol (total, HDL, and LDL), CRP, CBC, CT cardiac scoring, CT thoracic, CK and isoenzymes, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, echocardiography, echocardiography transesophageal, ECG, electrolytes, exercise stress test, glucose, glycated hemoglobin, gram stain, Hgb, Holter monitor, homocysteine, ketones, LDH and isoenzymes, lipoprotein electrophoresis, magnesium, MRI chest, MI infarct scan, IgE, lactic acid, lung perfusion scan, lung ventilation scan, myocardial perfusion heart scan, myoglobin, osmolality, pericardial fluid analysis, phosphorus, plethysmography, pleural fluid analysis, PET heart, PFT, potassium, pulse oximetry, TB skin test, and triglycerides. Related tests for pulmonary indications include α_1 -AT, anion gap, arterial/alveolar oxygen ratio, biopsy lung, bronchoscopy, carboxyhemoglobin, chest x-ray, chloride sweat, CBC, CBC hemoglobin, CBC WBC count and differential, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, electrolytes, gram stain, IgE, lactic acid, lung perfusion scan, lung ventilation scan, osmolality, phosphorus, plethysmography, pleural fluid analysis, and pulse oximetry.
- ▶ Refer to the Cardiovascular and Respiratory systems tables at the end of the book for related tests by body system.

Positron Emission Tomography, Pelvis

SYNONYM/ACRONYM: PET scan of the pelvis.

COMMON USE: To assess blood flow and metabolism to the pelvis toward diagnosis of disorders such as colorectal tumor, assist in tumor staging, and monitor the effectiveness of therapeutic interventions.

AREA OF APPLICATION: Pelvis.

CONTRAST: IV radioactive material (fluorodeoxyglucose [FDG]).

DESCRIPTION: Positron emission tomography (PET) combines the biochemical properties of nuclear medicine with the accuracy of computed tomography (CT). PET uses positron emissions from specific radionuclides (oxygen, nitrogen, carbon, and fluorine) to produce detailed functional images within the body. After the radionuclide becomes concentrated in the pelvis, PET images of blood flow or metabolic processes at the cellular level can be obtained. Colorectal tumor detection, tumor staging, evaluation of the effects of therapy, detection of recurrent disease, and detection of metastases are the main reasons to do a pelvic PET scan. Fluorine-18, in the form of fluorodeoxyglucose (FDG), is one of the more commonly used radionuclides. FDG is a glucose analogue, and because every cell uses glucose, the metabolic activity occurring in pelvic conditions such as colorectal cancer can be measured. There is little localization of FDG in normal tissue, allowing rapid detection of abnormal disease states.

The positron radiopharmaceuticals generally have short half-lives,

ranging from a few seconds to a few hours, and therefore they must be produced in a cyclotron located near where the test is being done. The PET scanner translates the emissions from the radioactivity as the positron combines with the negative electrons from the tissues and forms gamma rays that can be detected by the scanner. This information is transmitted to the computer, which determines the location and its distribution and translates the emissions as color-coded images for viewing, quantitative measurements, activity changes in relation to time, and three-dimensional computer-aided analysis. Each radionuclide tracer is designed to measure a specific body process, such as glucose metabolism, blood flow, or tissue perfusion.

The expense of the study and the limited availability of radiopharmaceuticals limit the use of PET, even though it is more sensitive than traditional nuclear scanning and single-photon emission computed tomography. Changes in reimbursement and the advent of mobile technology have increased the availability of this procedure in the community setting.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Determine the effects of therapy
- Determine the presence of colorectal cancer
- Determine the presence of metastases of a cancerous tumor
- Determine the recurrence of tumor or cancer
- Identify the site for biopsy

POTENTIAL DIAGNOSIS

Normal findings in

- Normal patterns of tissue metabolism, blood flow, and radionuclide distribution
- No focal uptake of radionuclide

Abnormal findings in

- Focal uptake of the radionuclide in pelvis
- Focal uptake in abnormal lymph nodes
- Focal uptake in tumor
- Focal uptake in metastases

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Drugs that alter glucose metabolism, such as tranquilizers or insulin, because hypoglycemia can alter PET results.
- The use of alcohol, tobacco, or caffeine-containing drinks at least 24 hr before the study, because the effects

of these substances would make it difficult to evaluate the patient's true physiological state (e.g., alcohol is a vasoconstrictor and would decrease blood flow to the target organ).

- Metallic objects within the examination field (e.g., jewelry, body rings), which may inhibit organ visualization and can produce unclear images.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Improper injection of the radionuclide that allows the tracer to seep deep into the muscle tissue produces erroneous hot spots.
- False-positive findings may occur as a result of normal gastrointestinal (GI) tract uptake and uptake in areas of infection or inflammation.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the pelvis related to abnormal organ function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium- or iodine-based contrast medium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a special department, usually in a radiology suite, by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives,

- radionuclides, medications used in the procedure, or emergency medications.
- ▶ Sometimes FDG examinations are done after blood has been drawn to determine circulating blood glucose levels. If blood glucose levels are high, insulin may be given.
- ▶ Instruct the patient to remove jewelry and other metallic objects in the area to be examined.
- ▶ Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure.
- ▶ Instruct the patient to restrict food for 4 hr; restrict alcohol, nicotine, or caffeine-containing drinks for 24 hr; and withhold medications for 24 hr before the test. Protocols may vary among facilities.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

- Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injecting radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners;** hematoma **related to blood leakage into the tissue following needle insertion;** infection **that might occur if bacteria from the skin surface is introduced at the puncture site;** nerve injury **that might occur if the needle strikes a nerve;** or UTI **related to use of a catheter.**
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.

- ▶ Ensure the patient has removed all jewelry and external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Place the patient in the supine position on an examination table.
- ▶ The radionuclide is injected, and imaging is started after a 45-min delay. Continuous scanning may be done for 1 hr. If comparative studies are indicated, additional injections of radionuclide may be needed.
- ▶ If required, the bladder may need to be lavaged via a urinary catheter with 2 L of 0.9% saline solution to remove concentrated radionuclide.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume pretest diet, fluids, medications, and activity.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed, to reduce discomfort or edema.
- ▶ Instruct the patient to drink increased amounts of fluids for 24 to 48 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 6 to 24 hr.
- ▶ Instruct the patient to flush the toilet immediately after each voiding and to meticulously wash hands with soap and water for 24 hr after the procedure.
- ▶ Tell all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated, about 3 days. Instruct her to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ No other radionuclide tests should be scheduled for 24 to 48 hr after this procedure.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of occult blood testing, colonoscopy, or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society (ACS) recommends regular screening for colon cancer, beginning at age 50 yr for individuals without identified risk factors. Their recommendations for frequency of screening: annual for occult blood testing (fecal occult blood testing [FOBT] and fecal immunochemical testing [FIT]); every 5 yr for flexible sigmoidoscopy, double contrast barium enema, and CT colonography; and every 10 yr for colonoscopy. There are both advantages and disadvantages to the screening tests that are available today. Methods to use DNA testing of stool are being investigated and await FDA approval. The DNA test is designed to identify abnormal changes in DNA from the cells in the lining of the colon that are normally shed and excreted in stool. The DNA tests under development use multiple markers to identify colon cancers that demonstrate different, abnormal DNA

changes. Unlike some of the current screening methods, the DNA tests would be able to detect precancerous polyps. The most current guidelines for colon cancer screening of the general population as well as of individuals with increased risk are available from the ACS (www.cancer.org), U.S. Preventive Services Task Force (www.uspreventiveservicestaskforce.org), and the American College of Gastroenterology (www.gi.org). Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include barium enema, biopsy intestinal, capsule endoscopy, cancer antigens, CT abdomen, fecal analysis, KUB, CT colonoscopy, MRI abdomen, and proctosigmoidoscopy.
- Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Potassium, Blood

SYNONYM/ACRONYM: Serum K⁺.

COMMON USE: To evaluate fluid and electrolyte balance related to potassium levels toward diagnosing disorders such as acidosis, renal failure, dehydration, and monitor the effectiveness of therapeutic interventions.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Ion-selective electrode)

Serum	Conventional & SI Units
Cord	5.6–12 mEq/L or mmol/L
1–12 hr	5.3–7.3 mEq/L or mmol/L
12–24 hr	5.3–8.9 mEq/L or mmol/L
24–48 hr	5.2–7.3 mEq/L or mmol/L
48–72 hr	5–7.7 mEq/L or mmol/L
3–7 days	3.2–5.5 mEq/L or mmol/L
8 days–1 mo	3.4–6 mEq/L or mmol/L
1–5 mo	3.5–5.6 mEq/L or mmol/L
6 mo–1 yr	3.5–6.1 mEq/L or mmol/L
2–19 yr	3.8–5.1 mEq/L or mmol/L
Adult–older adult	3.5–5.3 mEq/L or mmol/L

Note: Serum values are 0.1 mmol/L higher than plasma values, and reference ranges should be adjusted accordingly. It is important that serial measurements be collected using the same type of collection container to reduce variability of results from collection to collection.

Older adults are at risk for hyperkalemia due to the decline in aldosterone levels, decline in renal function, and effects of commonly prescribed medications that inhibit the renin-angiotensin-aldosterone system.

DESCRIPTION: Electrolytes dissociate into electrically charged ions when dissolved. Cations, including potassium, carry a positive charge. Body fluids contain approximately equal numbers of anions and cations, although the nature of the ions and their mobility differs between the intracellular and extracellular compartments. Both types of ions affect the electrical and osmolar functions of the body. Electrolyte quantities and the balance among them are controlled by oxygen and carbon dioxide exchange in the lungs; absorption, secretion, and excretion of many substances by the kidneys; and secretion of regulatory hormones by the endocrine glands. Potassium is the most abundant intracellular cation with a number of essential functions to include transmission of electrical impulses in cardiac and skeletal muscle and participation in enzyme reactions that transform glucose into energy and amino acids

into proteins. Potassium also helps maintain acid-base equilibrium, and it has a significant and inverse relationship to pH: A decrease in pH of 0.1 increases the potassium level by 0.6 mmol/L.

Abnormal potassium levels can be caused by a number of contributing factors, which can be categorized as follows:

Altered renal excretion: Normally, 80% to 90% of the body's potassium is filtered out through the kidneys each day (the remainder is excreted in sweat and stool); renal disease can result in abnormally high potassium levels.

Altered dietary intake: A severe potassium deficiency can be caused by an inadequate intake of dietary potassium.

Altered cellular metabolism: Damaged red blood cells (RBCs) release potassium into the circulating fluid, resulting in increased potassium levels.

This procedure is contraindicated for: N/A

INDICATIONS

- Assess a known or suspected disorder associated with renal disease, glucose metabolism, trauma, or burns
- Assist in the evaluation of electrolyte imbalances; this test is especially indicated in elderly patients, patients receiving hyperalimentation supplements, patients on hemodialysis, and patients with hypertension
- Evaluate cardiac arrhythmia to determine whether altered potassium levels are contributing to the problem, especially during digitalis therapy, which leads to ventricular irritability
- Evaluate the effects of drug therapy, especially diuretics
- Evaluate the response to treatment for abnormal potassium levels
- Monitor known or suspected acidosis, because potassium moves from RBCs into the extracellular fluid in acidotic states
- Routine screen of electrolytes in acute and chronic illness

POTENTIAL DIAGNOSIS

Increased in

- Acidosis (*intracellular potassium ions are expelled in exchange for hydrogen ions in order to achieve electrical neutrality*)
- Acute renal failure (*potassium excretion is diminished, and it accumulates in the blood*)
- Addison's disease (*due to lack of aldosterone, potassium excretion is diminished, and it accumulates in the blood*)
- Asthma (*related to chronic inflammation and damage to lung tissue*)
- Burns (*related to tissue damage and release by damaged cells*)
- Chronic interstitial nephritis (*potassium excretion is diminished, and it accumulates in the blood*)
- Dehydration (*related to hemoconcentration*)

- Dialysis (*dialysis treatments simulate kidney function, but potassium builds up between treatments*)
- Diet (*related to excessive intake of salt substitutes or of potassium salts in medications*)
- Exercise (*related to tissue damage and release by damaged cells*)
- Hemolysis (massive) (*potassium is the major intracellular cation*)
- Hyperventilation (*in response to respiratory alkalosis, blood levels of potassium are increased in order to achieve electrical neutrality*)
- Hypoaldosteronism (*due to lack of aldosterone, potassium excretion is diminished, and it accumulates in the blood*)
- Insulin deficiency (*insulin deficiency results in movement of potassium from the cell into the extracellular fluid*)
- Ketoacidosis (*insulin deficiency results in movement of potassium from the cell into the extracellular fluid*)
- Leukocytosis
- Muscle necrosis (*related to tissue damage and release by damaged cells*)
- Near drowning
- Pregnancy
- Prolonged periods of standing
- Tissue trauma (*related to release by damaged cells*)
- Transfusion of old banked blood (*aged cells hemolyze and release intracellular potassium*)
- Tubular unresponsiveness to aldosterone
- Uremia

Decreased in

- Alcoholism (*related to insufficient dietary intake*)
- Alkalosis (*potassium uptake by cells is increased in response to release of hydrogen ions from cells*)

- Anorexia nervosa (*related to significant changes in renal function that result in hypokalemia*)
- Bradycardia (*hypokalemia can cause bradycardia*)
- Chronic, excessive licorice ingestion (from licorice root) *Licorice inhibits short-chain dehydrogenase/reductase enzymes. These enzymes normally prevent cortisol from binding to aldosterone receptor sites in the kidney. In the absence of these enzymes, cortisol acts on the kidney and triggers the same effects as aldosterone, which include increased potassium excretion, sodium retention, and water retention.*
- Congestive heart failure (*related to fluid retention and hemodilution*)
- Crohn's disease (*insufficient intestinal absorption*)
- Cushing's syndrome (*aldosterone facilitates the excretion of potassium by the kidneys*)
- Diet deficient in meat and vegetables (*insufficient dietary intake*)
- Excess insulin (*insulin causes glucose and potassium to move into cells*)
- Familial periodic paralysis (*related to fluid retention*)
- Gastrointestinal (GI) loss due to vomiting, diarrhea, nasogastric suction, or intestinal fistula
- Hyperaldosteronism (*aldosterone facilitates the excretion of potassium by the kidneys*)
- Hypertension (*medications used to treat hypertension may result in loss of potassium; hypertension is often related to diabetes and renal disease, which affect cellular retention and renal excretion of potassium, respectively*)
- Hypomagnesemia (*magnesium levels tend to parallel potassium levels*)
- IV therapy with inadequate potassium supplementation
- Laxative abuse (*related to medications that cause potassium wasting*)
- Malabsorption (*related to insufficient intestinal absorption*)
- Pica (eating substances of no nutritional value, e.g., clay)
- Renal tubular acidosis (*condition results in excessive loss of potassium*)
- Sweating (*related to increased loss*)
- Theophylline administration, excessive (*theophylline drives potassium into cells, reducing circulating levels*)
- Thyrotoxicosis (*related to changes in renal function*)

CRITICAL FINDINGS

Adults & children

- Less than 2.5 mEq/L or mmol/L (SI: Less than 2.5 mEq/L or mmol/L)
- Greater than 6.2 mEq/L or mmol/L (SI: Greater than 6.2 mEq/L or mmol/L)

Newborns

- Less than 2.8 mEq/L or mmol/L (SI: Less than 2.8 mmol/L)
- Greater than 7.6 mEq/L or mmol/L (SI: Greater than 7.6 mmol/L)

Consideration may be given to verifying the critical findings before action is taken. Policies vary among facilities and may include requesting immediate recollection and retesting by the laboratory or retesting using a rapid Point of Care instrument at the bedside.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms, especially symptoms of fluid imbalance.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary

among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Symptoms of hyperkalemia include irritability, diarrhea, cramps, oliguria, difficulty speaking, and cardiac arrhythmias (peaked T waves and ventricular fibrillation). Continuous cardiac monitoring is indicated. Administration of sodium bicarbonate or calcium chloride may be requested. If the patient is receiving an IV supplement, verify that the patient is voiding.

Symptoms of hypokalemia include malaise, thirst, polyuria, anorexia, weak pulse, low blood pressure, vomiting, decreased reflexes, and electrocardiographic changes (depressed T waves and ventricular ectopy). Replacement therapy is indicated.

INTERFERING FACTORS

- Drugs that can cause an increase in potassium levels include ACE inhibitors, atenolol, basiliximab, captopril, clofibrate in association with renal disease, cyclosporine, dexamethasone, enalapril, etretinate, lisinopril in association with heart failure or hypertension, NSAIDs, some drugs with potassium salts, spironolactone, succinylcholine, and tacrolimus.
- Drugs that can cause a decrease in potassium levels include acetazolamide, acetylsalicylic acid, aldosterone, ammonium chloride,

amphotericin B, bendroflumethiazide, benzthiazide, bicarbonate, captopril, cathartics, chlorothiazide, chlorthalidone, cisplatin, clorexolone, corticosteroids, cyclothiazide, dichlorophenamide, digoxin, diuretics, enalapril, foscarnet, fosphenytoin, furosemide, insulin, laxatives, metolazone, moxalactam (common when coadministered with amikacin), large doses of any IV penicillin, phenolphthalein (with chronic laxative abuse), polythiazide, quinethazone, sodium bicarbonate, tacrolimus, IV theophylline, thiazides, triamterene, and trichlormethiazide. A number of these medications initially increase the serum potassium level, but they also have a diuretic effect, which promotes potassium loss in the urine except in cases of renal insufficiency.

- Leukocytosis, as seen in leukemia, causes elevated potassium levels.
- False elevations can occur with vigorous pumping of the hand during venipuncture. Hemolysis of the sample and high platelet counts also increase potassium levels, as follows:
 - (1) Because potassium is an intracellular ion and concentrations are approximately 150 times extracellular concentrations, even a slight amount of hemolysis can cause a significant increase in levels.
 - (2) Platelets release potassium during the clotting process, and therefore serum samples collected from patients with elevated platelet counts may produce spuriously high potassium levels. Plasma is the specimen of choice in patients known to have elevated platelet counts.
- False increases are seen in unprocessed samples left at room temperature because a significant amount of potassium leaks out of the cells within a few hours. Plasma or serum should be separated from cells within 4 hr of collection.

- Specimens should never be collected above an IV line because of the potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Electrolyte imbalance <i>(Related to metabolic imbalance associated with disease process)</i>	Excess: nausea, weak or irregular pulse; sudden collapse, cardiac arrest. Deficit: thirst; tetany; weakness; constipation; arrhythmias; hypotension; nausea; vomiting; anorexia; polyuria; mental depression; cardiac arrest	Correlate potassium imbalance with disease process, nutritional intake, renal function, medications; monitor ECG status; monitor for respiratory changes; minimize metabolic complications; provide a safe environment to prevent injury; collaborate with the pharmacist and HCP for appropriate pharmacologic interventions; adjust medication dosage to compensate for renal impairment; collaborate with dietician for dietary modifications; begin dialysis treatments if necessary (hemodialysis or peritoneal dialysis); reduce intake of high-potassium foods and dietary supplements
Health management <i>(Related to complexity of health-care system; complexity of therapeutic management; altered metabolic process resulting in increased or</i>	Health choices are ineffective in making a difference on outcomes; increasing symptoms of illness; verbalizes that therapeutic regime is too difficult; patient and family do not support HCP's suggestions	Assess effort to follow recommended regime; assess family or cultural factors that impact the success of the therapeutic regime; assess the patient's self-assessment of his or her health status; include the patient and family in designing the plan of care; tailor the plan of

Problem	Signs & Symptoms	Interventions
<p><i>decreased potassium; knowledge deficit; conflicted decision making; cultural family health patterns; barriers to healthy decisions; mistrust of HCP)</i></p>	<p>for health improvement; refusal to follow recommended therapeutic regime</p>	<p>care to the patient's lifestyle; collaborate with the patient and family to develop a system of managing own health; focus on behaviors that will make the biggest positive impact on improved health</p>
<p>Fluid volume (<i>Related to metabolic imbalances associated with disease process</i>)</p>	<p>Deficient: decreased urinary output, fatigue, and sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status. Overload: edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values</p>	<p>Record daily weight and monitor trends; record accurate intake and output; collaborate with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes as ordered; monitor serum potassium levels</p>
<p>Activity (<i>Related to compromised cardiac status; compromised renal status; weakness; lack of motivation; oxygen supply and demand imbalance</i>)</p>	<p>Verbal report of weakness; inability to tolerate activity; shortness of breath with activity; altered heart rate, blood pressure, and respiratory rate with activity</p>	<p>Assess current level of physical activity; take baseline vital signs; trend vital signs with activity; assess response to activity; monitor for oxygen desaturation with activity; administer</p>

(table continues on page 1284)

Problem

Signs & Symptoms

Interventions

prescribed oxygen with activity; collaborate with physical therapy to support activity; monitor blood pressure for orthostatic changes; collaborate with the patient to establish activity goals and guidelines; pace activities to match energy stores; assist with self-care

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating electrolyte balance.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex. Especially note complaints of weakness and confusion.
- ▶ Obtain a history of the patient's cardiovascular, endocrine, gastrointestinal, genitourinary, immune, and respiratory systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement. Instruct the patient not to clench and unclench the fist immediately before or during specimen collection.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Potassium is present in all plant and animal cells,

making dietary replacement simple to achieve in the potassium-deficient patient.

- ▶ Observe the patient for signs and symptoms of fluid volume excess related to excess potassium intake (hyperkalemia), fluid volume deficit related to active loss (hypokalemia), or risk of injury related to an alteration in body chemistry. Symptoms of hypokalemia and hyperkalemia include dehydration, diarrhea, vomiting, or prolonged anorexia.
- ▶ Increased potassium levels may be associated with dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric patients and other patients in whom renal function has deteriorated.
- ▶ Decreased potassium levels may occur in patients receiving digoxin or potassium-wasting diuretics. Potassium levels should be monitored carefully because cardiac arrhythmias can occur. Instruct the patient in electrolyte replacement therapy and changes in dietary intake that affect electrolyte levels, as ordered.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Recognize anxiety related to test results and answer any questions or address any concerns voiced by the patient or family.
- ▶ Educate the patient regarding access to nutritional counseling services. Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).

- ▶ Teach energy conservation techniques.
- ▶ Teach the appropriate use of assistive devices.

Expected Patient Outcomes:

Knowledge

- ▶ Describes the signs and symptoms of physical overactivity
- ▶ States their understanding that monitoring of serum potassium levels will be necessary to maintain health

Skills

- ▶ Demonstrates how to pace activities and conserve energies in the performance of the activities of daily living
- ▶ Identifies and lists foods that can increase potassium levels

Attitude

- ▶ Identifies concerns about activity tolerance
- ▶ Complies with the recommendation to access community resources to support a structured activity plan

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, aldosterone, anion gap, antiarrhythmic drugs, alveolar/arterial gradient, ANP, BNP, blood gases, BUN, calcium, carbon dioxide, chloride, complement, CBC hematocrit, CBC hemoglobin, CBC WBC count and differential, Coomb's antiglobulin (direct and indirect), cortisol, CK and isoenzymes, creatinine, DHEAS, echocardiography, echocardiography transesophageal, fecal fat, glucose, G6PD, Ham's test, haptoglobin, hemosiderin, insulin, ketones, lactic acid, lung perfusion scan, magnesium, osmolality, osmotic fragility, plethysmography, urine potassium, PFT, PK, renin, sickle cell screen, sodium, and US abdomen.
- ▶ Refer to the Cardiovascular, Endocrine, Gastrointestinal, Genitourinary, Immune, and Respiratory systems tables at the end of the book for related tests by body system.

Potassium, Urine

SYNONYM/ACRONYM: Urine K⁺.

COMMON USE: To evaluate electrolyte balance, acid-base balance, and hypokalemia.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Ion-selective electrode)

Age	Conventional Units	SI Units (Conventional Units × 1)
6–10 yr		
Male	17–54 mEq/24 hr or mmol/24 hr	17–54 mmol/24 hr
Female	8–37 mEq/24 hr or mmol/24 hr	8–37 mmol/24 hr
10–14 yr		
Male	22–57 mEq/24 hr or mmol/24 hr	22–57 mmol/24 hr
Female	18–58 mEq/24 hr or mmol/24 hr	18–58 mmol/24 hr
Adult–older adult	26–123 mEq/24 hr or mmol/24 hr	26–123 mmol/24 hr

Note: Reference values depend on potassium intake and diurnal variation. Excretion is significantly higher at night. Potassium excretion declines in older adults due to the decline in aldosterone levels, decline in renal function, and effects of commonly prescribed medications that inhibit the renin-angiotensin-aldosterone system.

DESCRIPTION: Electrolytes dissociate into electrically charged ions when dissolved. Cations, including potassium, carry a positive charge. Body fluids contain approximately equal numbers of anions and cations, although the nature of the ions and their mobility differs between the intracellular and extracellular compartments. Both types of ions affect the electrical and osmolar functions of the body. Electrolyte quantities and the balance among them are controlled by oxygen and carbon dioxide exchange in the lungs; absorption, secretion, and excretion of many substances by the kidneys; and secretion of regulatory hormones by the endocrine glands. Potassium is the most abundant intracellular

cation. It is essential for the transmission of electrical impulses in cardiac and skeletal muscle. It also functions in enzyme reactions that transform glucose into energy and amino acids into proteins. Potassium helps maintain acid-base equilibrium, and it has a significant and inverse relationship to pH: A decrease in pH of 0.1 increases the potassium level by 0.6 mEq/L.

Abnormal potassium levels can be caused by a number of contributing factors, which can be categorized as follows:

Altered renal excretion: Normally, 80% to 90% of the body's potassium is filtered out through the kidneys each day (the remainder is excreted in sweat and stool); renal disease can

result in abnormally high potassium levels.

Altered dietary intake: A severe potassium deficiency can be caused by an inadequate intake of dietary potassium.

Altered cellular metabolism: Damaged red blood cells (RBCs) release potassium into the circulating fluid, resulting in increased potassium levels.

Regulating electrolyte balance is one of the major functions of the kidneys. In normally functioning kidneys, urine potassium levels increase when serum levels are high and decrease when serum levels are low to maintain homeostasis. The kidneys respond to alkalosis by excreting potassium to retain hydrogen ions and increase acidity. In acidosis, the body excretes hydrogen ions and retains potassium. Analyzing these urinary levels can provide important clues to the functioning of the kidneys and other major organs. Urine potassium tests usually involve timed urine collections over a 12- or 24-hr period. Measurement of random specimens also may be requested.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine the potential cause of renal calculi
- Evaluate known or suspected endocrine disorder
- Evaluate known or suspected renal disease
- Evaluate malabsorption disorders

POTENTIAL DIAGNOSIS

Increased in

- Albright-type renal disease (**related to excessive production of cortisol**)
- Cushing's syndrome (**excessive corticosteroids, especially**

aldosterone levels, will increase urinary excretion of potassium)

- Diabetic ketoacidosis (**insulin deficiency forces potassium into the extracellular fluid; excess potassium is excreted in the urine**)
- Diuretic therapy (**related to potassium-wasting effects of the medications**)
- Hyperaldosteronism (**excessive aldosterone levels will increase urinary excretion of potassium**)
- Starvation (onset) (**cells involved in providing energy through tissue breakdown release potassium into circulation**)
- Vomiting (**elevated urine potassium is a hallmark of bulimia**)

Decreased in

- Addison's disease (**reduced aldosterone levels will diminish excretion of potassium by the kidneys**)
- Potassium deficiency (chronic)
- Renal failure with decreased urine flow

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that can cause an increase in urine potassium levels include acetazolamide, acetylsalicylic acid, ammonium chloride, bendroflumethiazide, carbenoxolone, chlorthalidone, clopamide, corticosteroids, cortisone, diapamide, dichlorophenamide, diuretics, ethacrynic acid, fludrocortisone, furosemide, hydrochlorothiazide, hydrocortisone, intramniotic saline, mefruside, niacinamide, some oral contraceptives, thiazides, torsemide, triflocin, and viomycin.
- Drugs that can cause a decrease in urine potassium levels include anesthetic agents, felodipine, and levarterenol.
- A dietary deficiency or excess of potassium can lead to spurious results.
- Diuretic therapy with excessive loss of electrolytes into the urine may falsely elevate results.

- All urine voided for the timed collection period must be included in the collection, or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.
- Potassium levels are subject to diurnal variation (output being highest at night), which is why 24-hr collections are recommended.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating electrolyte balance.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine, gastrointestinal, and genitourinary systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and

- to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- ▶ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

Random Specimen (Collect in Early Morning)

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling Catheter

- ▶ Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed Specimen

- ▶ Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- ▶ Begin the test between 6 and 8 a.m. if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- ▶ Include on the collection container's label the amount of urine, test start and stop times, and ingestion of any foods or medications that can affect test results.

General

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Potassium is present in all plant and animal cells, making dietary replacement simple to achieve in the potassium-deficient patient.
- ▶ Observe the patient for signs and symptoms of fluid volume excess related to excess potassium intake,

- fluid volume deficit related to active loss, or risk of injury related to an alteration in body chemistry. Symptoms include dehydration, diarrhea, vomiting, or prolonged anorexia. Instruct the patient in electrolyte replacement therapy and changes in dietary intake that affect electrolyte levels, as ordered.
- ▶ Increased potassium levels may be associated with dehydration. Evaluate the patient for signs and symptoms of dehydration. Dehydration is a significant and common finding in geriatric patients and other patients in whom renal function has deteriorated.
- ▶ Patients receiving digoxin or diuretics should have potassium levels monitored carefully because cardiac arrhythmias can occur.
- ▶ Increased urine potassium levels may be associated with the formation of kidney stones. Educate the patient, if appropriate, on the importance of drinking a sufficient amount of water when kidney stones are suspected.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, aldosterone, anion gap, BUN, calcium, calculus kidney stone panel, carbon dioxide, chloride, cortisol, creatinine, DHEAS, glucose, insulin, ketones, lactic acid, magnesium, osmolality, phosphorus, potassium, renin, sodium, and UA.
- ▶ Refer to the Endocrine, Gastrointestinal, and Genitourinary systems tables at the end of the book for related tests by body system.

Prealbumin

SYNONYM/ACRONYM: Transthyretin.

COMMON USE: To assess nutritional status and evaluate liver function toward diagnosing disorders such as malnutrition and chronic renal failure.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Nephelometry)

Age	Conventional Units	SI Units (Conventional Units × 10)
Newborn–1 mo	7–39 mg/dL	70–390 mg/L
1–6 mo	8–34 mg/dL	80–340 mg/L
6 mo–4 yr	2–36 mg/dL	20–360 mg/L
5–6 yr	12–30 mg/dL	120–300 mg/L
7 yr–adult/older adult	12–42 mg/dL	120–420 mg/L

DESCRIPTION: Prealbumin is a protein primarily produced by the liver. It is the major transport protein for triiodothyronine and thyroxine. It is also important in the metabolism of retinol-binding protein, which is needed for transporting vitamin A (retinol). Prealbumin has a short biological half-life of 2 days. This makes it a good indicator of protein status and an excellent marker for malnutrition. Prealbumin is often measured simultaneously with transferrin and albumin.

This procedure is contraindicated for: N/A

INDICATIONS

Evaluate nutritional status

POTENTIAL DIAGNOSIS

Increased in

- Alcoholism (*related to leakage of prealbumin from damaged*

hepatocytes and/or poor nutrition)

- Chronic renal failure (*related to rapid turnover of prealbumin, which reflects a perceived elevation in the presence of overall loss of other proteins that take longer to produce*)
- Patients receiving steroids (*these drugs stimulate production of prealbumin*)

Decreased in

- Acute-phase inflammatory response (*prealbumin is a negative acute-phase reactant protein; levels decrease in the presence of inflammation*)
- Diseases of the liver (*related to decreased ability of the damaged liver to synthesize protein*)
- Hepatic damage (*related to decreased ability of the damaged liver to synthesize protein*)
- Malnutrition (*synthesis is decreased due to lack of proper diet*)

- Tissue necrosis (*prealbumin is a negative acute-phase reactant protein; levels decrease in the presence of inflammation*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase prealbumin levels include anabolic steroids, anticonvulsants, danazol, oral contraceptives, prednisolone, prednisone, and propranolol.
- Drugs that may decrease prealbumin levels include amiodarone and diethylstilbestrol.
- Fasting 4 hr before specimen collection is highly recommended. Reference ranges are often based on fasting populations to provide some level of standardization for comparison. The presence of lipids in the blood may also interfere with the test method; fasting eliminates this potential source of error, especially if the patient has elevated lipid levels.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing nutritional status.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine, gastrointestinal, and hepatobiliary systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for 4 hr before specimen collection.
- ▶ Note that there are no fluid or medication restrictions, unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions; ensure that food has been restricted for at least 4 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, as directed by the HCP.
- ▶ **Nutritional Considerations:** Nutritional therapy may be indicated for patients

with decreased prealbumin levels. Educate the patient, as appropriate, that good dietary sources of complete protein (containing all eight essential amino acids) include meat, fish, eggs, and dairy products and that good sources of incomplete protein (lacking one or more of the eight essential amino acids) include grains, nuts, legumes, vegetables, and seeds.

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include albumin, chloride, ferritin, iron/TIBC, potassium, protein, sodium, T_4 , T_3 , transferrin, and vitamin A.
- Refer to the Endocrine, Gastrointestinal, and Hepatobiliary systems tables at the end of the book for related tests by body system.

Procalcitonin

SYNONYM/ACRONYM: PCT.

COMMON USE: To assist in diagnosing bacterial infection and risk for developing sepsis.

SPECIMEN: Serum (2 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (2 mL) collected in a lavender-top (EDTA) or a green-top (lithium or sodium heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Fluorescence immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 1)
Newborn	Less than 2 ng/mL	Less than 2 mcg/L
18–20 hr	Less than 20 ng/mL	Less than 20 mcg/L
48 hr	Less than 5 ng/mL	Less than 5 mcg/L
3 days–adult	Less than 0.1 ng/mL	Less than 0.1 mcg/L
Interpretive Guidelines		
Interpretation	Conventional Units	SI Units
Bacterial infection absent or very unlikely	Less than 0.1 ng/mL	Less than 0.1 mcg/L
Bacterial infection possible; low risk for development of sepsis	Less than 0.5 ng/mL	Less than 0.5 mcg/L

Interpretive Guidelines

Interpretation	Conventional Units	SI Units
Bacterial infection likely; development of sepsis is possible	0.5–2 ng/mL	0.5–2 mcg/L
Bacterial infection very likely; high risk for development of sepsis	2.1–9.9 ng/mL or greater	2.1–9.9 mcg/L or greater
Bacterial infection severe; septic shock is probable	10 ng/mL or greater	10 mcg/L or greater

DESCRIPTION: Sepsis is a very serious, potentially life-threatening systemic inflammatory response to infection. The host inflammatory reaction was termed *systemic inflammatory response syndrome* (SIRS) by the American College of Chest Physicians and the Society of Critical Care Medicine in 1992. SIRS is defined by documented clinical evidence of bacterial infection (e.g., culture results) in the presence of two of four other criteria: temperature greater than 100.4°F or less than 96.8°F; heart rate greater than 90 beats/min, hyperventilation (greater than 20 breaths/minute or $Paco_2$ less than 32 mm Hg), or white blood cell (WBC) count greater than 12×10^3 /microL or less than 4×10^3 /microL. The development of sepsis is initiated by the activation of circulating macrophages resulting from binding to receptors on the outer membrane of gram-negative or gram-positive bacteria. Other organisms, such as fungi, parasites, and viruses, are also capable of initiating SIRS, which can develop into sepsis. Severe sepsis involves a systemic inflammatory response that suppresses the immune system, activation of the coagulation process (reflected by prolonged

PT and aPTT, elevated D-dimer, and deficiency of protein C), cardiovascular insufficiency, and multiple organ failure. The incidence of sepsis in hospitals is especially high in noncardiac intensive care units. Early-onset neonatal sepsis occurs in the first 72 hours of life with 85% of cases presenting in the first 24 hours. Early-onset neonatal sepsis is the result of colonization of the neonate from the mother as it moved through the birth canal before delivery. The Centers for Disease Control and Prevention recommends universal screening for group B *Streptococcus* for all pregnant women at 35 to 37 weeks' gestation. Other organisms associated with early-onset neonatal sepsis include coagulase-negative *Staphylococcus*, *Escherichia coli*, *Haemophilus influenzae*, and *Listeria monocytogenes*.

Late-onset neonatal sepsis, during days 4 to 90, is acquired from the environment and has been associated with infection by *Acinetobacter*, *Candida*, coagulase-negative *Staphylococci*, *Enterobacter*, *E. coli*, group B *Streptococcus*, *Klebsiella*, *Pseudomonas*, *Serratia*, and *Staphylococcus aureus*, as well as some anaerobes. Normally

procalcitonin, the precursor of the hormone calcitonin, is produced by the C cells of the thyroid. In SIRS, microbial toxins and inflammatory mediator proteins, including cytokines, tumor necrosis factor α , interleukin 1, prostaglandins, and platelet activating factor, may trigger the production of large amounts of procalcitonin by nonthyroidal, non-neuroendocrine cells throughout the body. Each phase of the inflammatory response creates another cascade of events that may conclude with septic shock and death. Procalcitonin is detectable within 2 to 4 hr after an SIRS-initiating event and peaks within 12 to 24 hr. Serial measurements are useful to monitor patients at risk of developing sepsis or to monitor response to therapy.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of bacteremia and septicemia
- Assist in the differential diagnosis of bacterial versus viral meningitis
- Assist in the differential diagnosis of community-acquired bacterial versus viral pneumonia
- Monitor response to antibacterial therapy

POTENTIAL DIAGNOSIS

Increased in

- Bacteremia or septicemia (*related to SIRS induced overproduction of procalcitonin*)
- Major surgery (*related to inflammation in the absence of sepsis*)
- Multiorgan failure (*related to inflammation in the absence of sepsis*)

- Neuroendocrine tumors (medullary thyroid cancer, small-cell lung cancer, and carcinoid tumors) (*related to procalcitonin [PCT]-secreting tumor cells*)
- Severe burns (*related to inflammation in the absence of sepsis*)
- Severe trauma (*related to inflammation in the absence of sepsis*)
- Treatment with OKT3 antibodies (antibody used to protect a transplanted organ or graft from attack by T cells and subsequent rejection) and other drugs that stimulate the release of cytokines (*related to inflammatory response in the absence of sepsis*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for infection and response to antibiotic treatment.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex. The patient may complain of pain related to the inflammatory process in connective or other tissues.
- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site

for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ALKP, ALT, AST, antimicrobial drugs, bilirubin total and fractions, coagulation factors, CBC, CBC platelet count, CBC WBC count and differential, creatinine, CRP, culture bacterial blood, culture bacterial anal/genital, culture bacterial urine, ESR, Gram stain, lactic acid, aPTT, PT, and Protein C.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Proctosigmoidoscopy

P

SYNONYM/ACRONYM: Anoscopy (anal canal), proctoscopy (rectum), flexible fiberoptic sigmoidoscopy, flexible proctosigmoidoscopy, sigmoidoscopy (sigmoid colon).

COMMON USE: To visualize and assess the colon, rectum, and anus to assist in diagnosing disorders such as cancer, inflammation, prolapse, and evaluate the effectiveness of medical and surgical therapeutic interventions.

AREA OF APPLICATION: Anus, rectum, colon.

CONTRAST: Air.

DESCRIPTION: Proctosigmoidoscopy allows direct visualization of the mucosa of the anal canal (anoscopy), rectum (proctoscopy), and distal sigmoid colon (sigmoidoscopy). The procedure can be performed using a rigid or flexible fiberoptic endoscope, but the flexible instrument is generally preferred. The endoscope is a multichannel device allowing visualization of the mucosal lining of the colon, instillation of air, removal of fluid and foreign objects, obtainment of tissue biopsy specimens, and use of a laser for the destruction of tissue and control of bleeding. The endoscope is advanced approximately 60 cm into the colon. This procedure is commonly used in patients with lower abdominal and perineal pain; changes in bowel habits; rectal prolapse during defecation; or passage of blood, mucus, or pus in the stool. Proctosigmoidoscopy can also be a therapeutic procedure, allowing removal of polyps or hemorrhoids or reduction of a volvulus. Biopsy specimens of suspicious sites may be obtained during the procedure.

large abdominal aortic or iliac aneurysm, or coagulation abnormality.

INDICATIONS

- Confirm the diagnosis of diverticular disease
- Confirm the diagnosis of Hirschsprung's disease and colitis in children
- Determine the cause of pain and rectal prolapse during defecation
- Determine the cause of rectal itching, pain, or burning
- Evaluate the cause of blood, pus, or mucus in the stool
- Evaluate postoperative anastomosis of the colon
- Examine the distal colon before barium enema (BE) x-ray to obtain improved visualization of the area, and after a BE when x-ray findings are inconclusive
- Reduce volvulus of the sigmoid colon
- Remove hemorrhoids by laser therapy
- Screen for and excise polyps
- Screen for colon cancer

POTENTIAL DIAGNOSIS

Normal findings in

- Normal mucosa of the anal canal, rectum, and sigmoid colon

Abnormal findings in

- Anal fissure or fistula
- Anorectal abscess
- Benign lesions
- Bleeding sites
- Bowel infection or inflammation
- Crohn's disease
- Diverticula
- Hypertrophic anal papillae
- Internal and external hemorrhoids
- Polyps
- Rectal prolapse
- Tumors
- Ulcerative colitis
- Vascular abnormalities

This procedure is contraindicated for

-  Patients with bleeding disorders, especially disorders associated with uremia and cytotoxic chemotherapy.
-  Patients with cardiac conditions or arrhythmias.
-  Patients with bowel perforation, acute peritonitis, ischemic bowel necrosis, toxic megacolon, diverticulitis, recent bowel surgery, advanced pregnancy, severe cardiac or pulmonary disease, recent myocardial infarction, known or suspected pulmonary embolus,

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Strictures or other abnormalities preventing passage of the scope.
- Barium swallow or upper gastrointestinal (GI) series within the preceding 48 hr.
- Severe lower GI bleeding or the presence of feces, barium, blood, or blood clots.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Use of bowel preparations that include laxatives or enemas should be avoided in pregnant patients or patients with inflammatory bowel disease unless specifically directed by a health-care provider (HCP).

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating the rectum and lower colon for disease.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
- ▶ Obtain a history of the patient's gastrointestinal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Note any recent procedures that can interfere with test results. Ensure that this procedure is performed before an upper GI study or barium swallow.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note time and date of last dose.
- ▶ Note intake of oral iron preparations within 1 wk before the procedure because these cause black, sticky feces that are difficult to remove with bowel preparation.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to insertion of the anoscope. Inform the patient that the procedure is performed in a GI lab by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient that a laxative may be needed the day before the procedure, with cleansing enemas on the morning of the procedure, depending on the institution's policy.
- ▶ Inform the patient that the urge to defecate may be experienced when the scope is passed. Encourage slow, deep breathing through the mouth to help alleviate the feeling.
- ▶ Inform the patient that flatus may be expelled during and after the procedure owing to air that is injected into the scope to improve visualization.
- ▶ Instruct the patient to eat a low-residue diet for 3 days prior to the procedure. Consume clear liquids only the evening

before, and restrict food and fluids for 8 hr prior to the procedure. Protocols may vary among facilities.

- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*

INTRATEST:

Potential Complications:

Complications of the procedure may include bleeding and cardiac arrhythmias.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with food, fluid, and medication restrictions and pretesting preparations.
- ▶ Administer two small-volume enemas 1 hr before the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and change into the gown, robe, and foot coverings provided.
- ▶ Record baseline vital signs and continue to monitor throughout the procedure. Protocols may vary among facilities.
- ▶ Place the patient on an examination table in the left lateral decubitus position or the knee-chest position and drape with the buttocks exposed. The buttocks are placed at or extending slightly beyond the edge of the examination table or bed, preferably on a special examining table that tilts the patient into the desired position.
- ▶ The HCP visually inspects the perianal area and then performs a digital rectal examination with a well-lubricated, gloved finger. A fecal specimen may be obtained from the glove when the finger is removed from the rectum.
- ▶ A lubricated anoscope (7 cm in length) is inserted, and the anal canal is inspected (anoscopy). The anoscope is removed, and a lubricated proctoscope (27 cm in length) or flexible sigmoidoscope (35 to 60 cm in length) is inserted.
- ▶ The scope is manipulated gently to facilitate passage, and air may be insufflated through the scope to

improve visualization. Suction and cotton swabs also are used to remove materials that hinder visualization.

- ▶ The patient is instructed to take deep breaths to aid in movement of the scope downward through the ascending colon to the cecum and into the terminal portion of the ileum.
- ▶ Examination is done as the scope is gradually withdrawn. Photographs are obtained for future reference.
- ▶ At the end of the procedure, the scope is completely withdrawn, and residual lubricant is cleansed from the anal area.
- ▶ Place fecal or tissue samples and polyps in properly labeled specimen containers, and promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Monitor temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature changes. Protocols may vary among facilities.
- ▶ Monitor for any rectal bleeding.
- ▶ Instruct the patient to resume diet, medication, and activity, as directed by the HCP.
- ▶ Instruct the patient to expect slight rectal bleeding for 2 days after removal of polyps or biopsy specimens, but heavy rectal bleeding must be immediately reported to the HCP.
- ▶ Instruct the patient that any abdominal pain, tenderness, or distention; pain on defecation; or fever must be reported to the HCP immediately.
- ▶ Inform the patient that any bloating or flatulence is the result of air insufflation.
- ▶ Encourage the patient to drink several glasses of water to help replace fluid lost during test preparation.
- ▶ Recognize anxiety related to test results, and be supportive of perceived

loss of independence and fear of shortened life expectancy. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Decisions regarding the need for and frequency of occult blood testing, colonoscopy, or other cancer screening procedures should be made after consultation between the patient and HCP. The American Cancer Society (ACS) recommends regular screening for colon cancer, beginning at age 50 yr for individuals without identified risk factors. Their recommendations for frequency of screening are as follows: annual for occult blood testing (fecal occult blood testing [FOBT] and fecal immunochemical testing [FIT]); every 5 yr for flexible sigmoidoscopy, double contrast barium enema, and CT colonography; and every 10 yr for colonoscopy. There are both advantages and disadvantages to the screening tests that are available today. Methods to use DNA testing of stool are being investigated and await FDA approval. The DNA test is designed to identify abnormal changes in DNA from the

cells in the lining of the colon that are normally shed and excreted in stool. The DNA tests under development use multiple markers to identify colon cancers that demonstrate different, abnormal DNA changes. Unlike some of the current screening methods, the DNA tests would be able to detect precancerous polyps. The most current guidelines for colon cancer screening of the general population as well as of individuals with increased risk are available from the ACS (www.cancer.org), U.S. Preventive Services Task Force (www.uspreventiveservicestaskforce.org), and the American College of Gastroenterology (www.gi.org). Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include barium enema, capsule endoscopy, colonoscopy, CBC, CT abdomen, fecal analysis, fecal fat, GI blood loss scan, MRI abdomen, and US prostate transrectal.
- ▶ Refer to the Gastrointestinal System table at the end of the book for related tests by body system.

Progesterone

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess ovarian function, assist in fertility work-ups, and monitor placental function during pregnancy related to disorders such as tumor, cysts, and threatened abortion.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunochemiluminometric assay [ICMA])

Hormonal State	Conventional Units	SI Units (Conventional Units × 0.0318)
Prepubertal	7–52 ng/dL	0.2–1.7 nmol/L
Adult male	13–97 ng/dL	0.4–3.1 nmol/L
Adult female		
Follicular phase	15–70 ng/dL	0.5–2.2 nmol/L
Luteal phase	200–2,500 ng/dL	6.4–79.5 nmol/L
Pregnancy, first trimester	725–4,400 ng/dL	23–140 nmol/L
Pregnancy, second trimester	1,950–8,250 ng/dL	62–262.4 nmol/L
Pregnancy, third trimester	6,500–22,900 ng/dL	206.7–728.2 nmol/L
Postmenopausal period	Less than 40 ng/dL	Less than 1.3 nmol/L

DESCRIPTION: Progesterone is a female sex hormone. Its function is to prepare the uterus for pregnancy and the breasts for lactation. Progesterone testing can be used to confirm that ovulation has occurred and to assess the functioning of the corpus luteum. Serial measurements can be performed to help determine the day of ovulation.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of luteal-phase defects (performed in conjunction with endometrial biopsy)
- Evaluate patients at risk for early or spontaneous abortion
- Identify patients at risk for ectopic pregnancy and assessment of corpus luteum function
- Monitor patients ovulating during the induction of human chorionic gonadotropin (HCG), human menopausal gonadotropin, follicle-stimulating hormone/luteinizing hormone-releasing hormone, or clomiphene (serial measurements can assist in pinpointing the day of ovulation)
- Monitor patients receiving progesterone replacement therapy

POTENTIAL DIAGNOSIS

Increased in

- Chorioepithelioma of the ovary (*related to progesterone-secreting tumor*)
- Congenital adrenal hyperplasia (*related to excessive production of progesterone precursors*)
- Hydatidiform mole (*related to progesterone-secreting tumor*)
- Lipoid ovarian tumor (*related to progesterone-secreting tumor*)
- Ovulation (*related to normal production of progesterone*)
- Pregnancy (*related to normal production of progesterone*)
- Theca lutein cyst (*related to progesterone-secreting cyst*)

Decreased in

- Galactorrhea-amenorrhea syndrome (*progesterone is not produced in the absence of ovulation*)
- Primary or secondary hypogonadism (*related to diminished production of progesterone*)
- Short luteal-phase syndrome (*related to diminished time frame for production and secretion*)
- Threatened abortion, fetal demise, toxemia of pregnancy, pre-eclampsia, placental failure (*related to decreased production by threatened placenta*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase progesterone levels include clomiphene, corticotropin, hydroxyprogesterone, ketoconazole, mifepristone, progesterone, tamoxifen, and valproic acid.
- Drugs that may decrease progesterone levels include ampicillin, danazol, epostane, goserelin, and leuprolide.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating hormone level during pregnancy.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and provide support. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide a nonjudgmental, nonthreatening atmosphere for exploring other options (e.g., adoption). Educate the patient regarding access to counseling services, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient in the use of home pregnancy test kits approved by the U.S. Food and Drug Administration. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process

and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▶ Related tests include ACTH, AFP, amniotic fluid analysis, antibodies

cardiolipin, biopsy chorionic villus, estradiol, fetal fibronectin, FSH, HCG, LH, prolactin, testosterone, and US BPP obstetric.

▶ Refer to the Endocrine and Reproductive systems tables at the end of the book for related tests by body system.

Prolactin

SYNONYM/ACRONYM: Luteotropic hormone, lactogenic hormone, lactogen, HPRL, PRL.

COMMON USE: To assess for lactation disorders and identify the presence of prolactin-secreting tumors to assist in diagnosing disorders such as lactation failure.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Specimen should be transported tightly capped and in an ice slurry.

NORMAL FINDINGS: (Method: Immunoassay)

Age	Conventional Units	SI Units (Conventional Units × 1)
Prepubertal males and females	3.2–20 ng/mL	3.2–20 mcg/L
Adult males	4–23 ng/mL	4–23 mcg/L
Adult females	4–30 ng/mL	4–30 mcg/L
Pregnant	5.3–215.3 ng/mL	5.3–215.3 mcg/L
Postmenopausal	2.4–24 ng/mL	2.4–24 mcg/L

DESCRIPTION: Prolactin is a hormone secreted by the pituitary gland. It is normally elevated in pregnant and lactating females. The main function of prolactin is to induce and sustain milk production in lactating females. Prolactin levels rise late in pregnancy, peak with the initiation of lactation, and surge each time a woman breastfeeds. Prolactin levels are highest at night during

sleep and shortly after awakening. Levels are known to increase during periods of physical and emotional stress. Elevated prolactin levels are also known to affect fertility by inhibiting secretion of gonadotropin-releasing hormone (GnRH) from the hypothalamus; thereby also inhibiting secretion of LH and FSH from the pituitary gland and suppressing ovulation. Reduced fertility during lactation

offers some natural protection against pregnancy. The function of prolactin in males and nonpregnant females is unknown but there is an association between high levels and infertility.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of primary hypothyroidism, as indicated by elevated levels
- Assist in the diagnosis of suspected tumor involving the lungs or kidneys (elevated levels indicating ectopic prolactin production)
- Evaluate failure of lactation in the postpartum period
- Evaluate sexual dysfunction of unknown cause in men and women
- Evaluate suspected postpartum hypophyseal infarction (Sheehan's syndrome), as indicated by decreased levels

POTENTIAL DIAGNOSIS

Increased in

- Adrenal insufficiency (*secondary to hypopituitarism*)
- Amenorrhea (*pathophysiology is unclear*)
- Anorexia nervosa (*pathophysiology is unclear*)
- Breastfeeding (*stimulates secretion of prolactin*)
- Chiari-Frommel and Argonz-Del Castillo syndromes (*endocrine disorders in which pituitary or hypothalamic tumors secrete excessive amounts of prolactin*)
- Chest wall injury (*trauma in this location can stimulate production of prolactin*)
- Chronic renal failure (*related to decreased renal excretion*)
- Ectopic prolactin-secreting tumors (e.g., lung, kidney)

- Galactorrhea (*production of breast milk related to prolactin-secreting tumor*)
- Hypothalamic and pituitary disorders
- Hypothyroidism (primary) (*related to pituitary gland dysfunction*)
- Pituitary tumor
- Polycystic ovary (Stein-Leventhal) syndrome
- Pregnancy
- Shingles
- Stress (*stimulates secretion of prolactin*)
- Surgery (pituitary stalk section)

Decreased in

- Sheehan's syndrome (*severe hemorrhage after obstetric delivery that causes pituitary infarct; secretion of all pituitary hormones is diminished*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and hormones that may increase prolactin levels include amitriptyline, amoxapine, azosemide, benserazide, butaperazine, butorphanol, carbidopa, chlorophenylpiperazine, chlorpromazine, cimetidine, clomipramine, desipramine, diethylstilbestrol, enalapril, β -endorphin, enflurane, fenfluramine, fenoldopam, flunarizine, fluphenazine, fluvoxamine, furosemide, growth hormone-releasing hormone, haloperidol, hexarelin, imipramine, insulin, interferon-b, labetalol, loxapine, megestrol, mestranol, methyl dopa, metoclopramide, molindone, morphine, nitrous oxide, oral contraceptives, oxcarbazepine, parathyroid hormone, pentagastrin, perphenazine, phenytoin, pimozide, prochlorperazine, promazine, ranitidine, remoxipride, reserpine, sulphiride, sultopride, thiethylperazine, thioridazine, thiothixene,

thyrotropin-releasing hormone, trifluoperazine, trimipramine, tumor necrosis factor, veralipride, verapamil, and zometapine.

- Drugs and hormones that may decrease prolactin levels include anticonvulsants, apomorphine, bromocriptine, cabergoline, calcitonin, cyclosporine, dexamethasone, D-Trp-6-LHRH, levodopa, metoclopramide, morphine, nifedipine, octreotide, pergolide, ranitidine, rifampin, ritanserin, ropinirole, secretin, and tamoxifen.
- Episodic elevations can occur in response to sleep, stress, exercise, hypoglycemia, and breastfeeding.
- Venipuncture can cause falsely elevated levels.
- Prolactin secretion is subject to diurnal variation with highest levels occurring in the morning.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that test can assist in evaluating breast feeding hormone level.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Specimen collection should occur

between 8 and 10 a.m. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to fast for 12 hr before specimen collection because hyperglycemia can cause a short-term increase in prolactin levels.
- ▶ Note that there are no fluid or medication restrictions unless by medical direction.
- ▶ Prepare an ice slurry in a cup or plastic bag to have on hand for immediate transport of the specimen to the laboratory.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with dietary restrictions; ensure that food has been restricted for at least 12 hr prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. The specimen should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, as directed by the HCP.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be

performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACE, BMD, CT pituitary, DHEAS, estradiol, FSH, GH, HCG, insulin, laparoscopy gynecologic, LH, MRI pituitary, progesterone, RAIU, TSH, and thyroxine.
- ▶ Refer to the Endocrine and Reproductive systems tables at the end of the book for related tests by body system.

Prostate-Specific Antigen

SYNONYM/ACRONYM: PSA.

COMMON USE: To assess prostate health and assist in diagnosis of disorders such as prostate cancer, inflammation, and benign tumor and to evaluate effectiveness of medical and surgical therapeutic interventions.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunoassay)

Gender	Conventional Units	SI Units (Conventional Units x 1)
Male	Less than 4 ng/mL	Less than 4 mcg/L
Post-radical prostatectomy (30–60 d)	Less than 0.1 ng/mL	Less than 0.1 mcg/L
Female	Less than 0.5 ng/mL	Less than 0.5 mcg/L

DESCRIPTION: Prostate-specific antigen (PSA) is produced exclusively by the epithelial cells of the prostate, periurethral, and perirectal glands. Used in conjunction with the digital rectal examination (DRE), PSA is a useful test for identifying and monitoring cancer

of the prostate. Risk of diagnosis is higher in African American men, who are 61% more likely than Caucasian men to develop prostate cancer. Family history and age at diagnosis are other strong correlating factors. PSA circulates in both free and bound (complexed)

forms. A low ratio of free to complexed PSA (i.e., less than 10%) is suggestive of prostate cancer; a ratio of greater than 30% is rarely associated with prostate cancer. PSA velocity, the rate of PSA increase over time, is being used to identify the potential aggressiveness of the cancer. Approximately 15% to 40% of patients who have had their prostate removed will encounter an increase in PSA. Patients treated for prostate cancer and who have had a PSA recurrence can still develop a metastasis for as long as 8 years after the post-surgical PSA level increased. The majority of prostate tumors develop slowly and require minimal intervention, but patients with an increase in PSA greater than 2 ng/mL in a year are more likely to have an aggressive form of prostate cancer with a greater risk of death.

The Prostate Health Index (PHI) is another multi-marker strategy being used to improve the positive prediction rate of prostate cancer, especially when PSA levels are considered to be moderately increased (between 4–10 ng/mL). The PHI applies information provided by the results of prostate marker blood tests to a mathematical formula and offers additional information for clinical decision making. The 3 tests used in the formula are the total PSA, free PSA, and p2PSA (an isoform of PSA) where:

$$\text{PHI} = \text{p2PSA}/(\text{free PSA} \times \text{total PSA})$$

PHI less than 27% have a relatively low probability for prostate cancer, PHI between 27% and 55% predict a moderate probability for prostate cancer, and PHI greater than 55% have an increased risk for prostate cancer.

Personalized medicine provides a technology to predict the progression of prostate cancer, likelihood of recurrence, or development of related metastatic disease. New technology makes it possible to combine data such as analysis of molecular biomarkers and cellular structure specific to the individual's biopsy tissue, standard tissue biopsy results, Gleason score, number of positive tumor cores, tumor stage, presurgical and postsurgical PSA levels, and postsurgical margin status with computerized mathematical programs to create a personalized report that predicts the likelihood of post-prostatectomy disease progression. Serial measurements of PSA in the blood are often performed before and after surgery.

PSA is also produced in females, most notably in breast tissue. There is some evidence that elevated PSA levels in breast cancer patients are associated with positive estrogen and progesterone status.

Important note: When following patients using serial testing, the same method of measurement should be consistently used.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate the effectiveness of treatment for prostate cancer (prostatectomy): Levels decrease if treatment is effective; rising levels are associated with recurrence and a poor prognosis
- Investigate or evaluate an enlarged prostate gland, especially if prostate cancer is suspected
- Stage prostate cancer

POTENTIAL DIAGNOSIS

Increased in

A breach in the protective barrier between the prostatic lumen and the bloodstream due to significant disease will allow measurable levels of circulating PSA.

- Benign prostatic hypertrophy
- Prostate cancer
- Prostatic infarct
- Prostatitis
- Urinary retention

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that decrease PSA levels include buserelin, dutasteride, finasteride, and flutamide.
- Increases may occur if ejaculation occurs within 24 hr prior to specimen collection. Increases can occur due to prostatic needle biopsy, cystoscopy, or prostatic infarction either by undergoing catheterization or the presence of an indwelling catheter; therefore, specimens should be collected prior to or 6 wk after the procedure. There is conflicting information regarding the effect of DRE on PSA values, and some health-care providers (HCPs) may specifically request specimen collection prior to DRE.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Knowledge <i>(Related to postoperative care and treatment secondary to prostate cancer)</i>	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management; verbalization of inaccurate information	Assess the patient's understanding of the need for further treatment, radiation therapy, chemotherapy; discuss postoperative infection risk and the associated signs and symptoms; discuss the possibility of postoperative incontinence and erectile dysfunction
Fear <i>(Related to lack of understanding about diagnosis; treatment; potential death)</i>	Anxiety; apprehension; verbalization of fear; restlessness; increased tension; continuous questioning; increased blood pressure, heart rate, respiratory rate	Evaluate verbal and nonverbal indicators of fear; assess for the cause of fear; acknowledge the patient's awareness of his or her fear; explain all procedures with simple age- and culturally appropriate language; administer prescribed mild tranquilizer; maintain a confident, assured professional manner in all patient interactions

(table continues on page 1308)

Problem	Signs & Symptoms	Interventions
Hopelessness <i>(Related to chronic illness; impaired functionality; prolonged pain and discomfort)</i>	Decreased affect; decreased response to stimuli; feeling of emptiness; alterations in sleep patterns and appetite; expressions of apathy; withdrawn; states life has no meaning	Assess role of illness in relation to expressions of helplessness; assess level of appetite; assess verbalization of helplessness; provide opportunities to express feelings in a safe environment; support development of a trusting relationship to decrease feelings of isolation; encourage verbalization of personal strengths and weaknesses; encourage realistic hope; assist in identification of coping skills
Powerlessness <i>(Related to chronic illness; treatment for illness; loss of ability to provide self-care; progressive debilitation; terminal prognosis; changes in sexuality)</i>	Expression of loss of control over situation, self, outcome of disease; passive; apathetic; submissive; decreased participation in self-care; reluctant to express feelings	Assess need to be in control; assess feelings of hopelessness, depression, apathy; assist to identify situations that contribute to a feeling of powerlessness; assess the impact of the sense of powerlessness on the patient's sense of self; encourage verbalization of feelings; discuss therapeutic options offered by HCP; assist to identify strengths; identify coping strategies; encourage being responsible for self-care and personal environment to increase sense of control; receive positive feedback

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing prostate health.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** There is growing evidence that inflammation and oxidation play key roles in the development of numerous diseases, including prostate cancer. Research also indicates that diets containing dried beans, fresh fruits and vegetables, nuts, spices, whole grains, and smaller amounts of red meats can increase the amount of protective antioxidants. Regular exercise, especially in combination with a healthy diet, can bring about changes in the body's metabolism that decrease inflammation and oxidation.
- ▶ Recognize anxiety related to test results, and offer support. Counsel the patient, as appropriate, that sexual

dysfunction related to altered body function, drugs, or radiation may occur. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Recommendations made by various medical associations and national health organizations regarding prostate cancer screening are moving away from routine PSA screening and toward informed decision making. The American Cancer Society's (ACS) guidelines recommend that discussions about screening should begin at age 50 yr for men at average risk, 45 yr for men at high risk, and 40 yr for men at the highest risk of developing prostate cancer. Educate the patient regarding access to counseling services. Provide contact information, if desired, for the Prostate Cancer Foundation (www.prostatecancerfoundation.org).

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Answer any questions or address any concerns voiced by the patient or family.
- ▶ Note that decisions regarding the need for and frequency of routine PSA testing or other cancer screening procedures should be made after consultation between the patient and HCP.
- ▶ Consult the most current guidelines for prostate cancer screening of the general population as well as of individuals with increased risk which are available from the ACS (www.cancer.org) and the American Urological Association (www.aua.org).

Expected Patient Outcomes:**Knowledge**

- ▶ States understanding that postoperative urinary incontinence may occur and take up to a year to resolve
- ▶ States understanding that erectile dysfunction may occur as a postoperative complication

Skills

- ▶ Describes the correct technique for the self-administration of a sitz bath
- ▶ Accurately describes how to perform Kegel exercises to improve control over urination

Attitude

- ▶ Complies with the request to perform sitz baths to facilitate wound healing and prevent infection
- ▶ Complies with the recommended follow-up appointments

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy prostate (with Gleason score), cystoscopy, cystourethrography voiding, PAP, retrograde ureteropyelography, semen analysis, and US prostate.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Protein, Blood, Total and Fractions

SYNONYM/ACRONYM: TP, SPEP (fractions include albumin, α_1 -globulin, α_2 -globulin, β -globulin, and γ -globulin).

COMMON USE: To assess nutritional status related to various disease and conditions such as dehydration, burns, and malabsorption.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Spectrophotometry for total protein, electrophoresis for protein fractions)

Total Protein

Age	Conventional Units	SI Units (Conventional Units × 10)
Newborn–5 days	3.8–6.2 g/dL	38–62 g/L
1–3 yr	5.9–7 g/dL	59–70 g/L
4–6 yr	5.9–7.8 g/dL	59–78 g/L
7–9 yr	6.2–8.1 g/dL	62–81 g/L
10–19 yr	6.3–8.6 g/dL	63–86 g/L
Adult	6–8 g/dL	60–80 g/L

Values may be slightly decreased in older adults due to insufficient intake or the effects of medications and the presence of multiple chronic or acute diseases with or without muted symptoms.

Protein Fractions

	Conventional Units	SI Units (Conventional Units \times 10)
Albumin	3.4–4.8 g/dL	34–48 g/L
α_1 -Globulin	0.2–0.4 g/dL	2–4 g/L
α_2 -Globulin	0.4–0.8 g/dL	4–8 g/L
β -Globulin	0.5–1 g/dL	5–10 g/L
γ -Globulin	0.6–1.2 g/dL	6–12 g/L

Values may be slightly decreased in older adults due to insufficient intake or the effects of medications and the presence of multiple chronic or acute diseases with or without muted symptoms.

DESCRIPTION: Protein is essential to all physiological functions. Proteins consist of amino acids, the building blocks of blood and body tissues. Protein is also required for the regulation of metabolic processes, immunity, and proper water balance. Total protein includes albumin and globulins. Albumin, the protein present in the highest concentrations, is the main transport protein in the body. Albumin also significantly affects plasma oncotic pressure, which regulates the distribution of body fluid between blood vessels, tissues, and cells. α_1 -Globulin includes α_1 -antitrypsin, α_1 -fetoprotein, α_1 -acidglycoprotein, α_1 -antichymotrypsin, inter- α_1 -trypsin inhibitor, high-density lipoproteins, and group-specific component (vitamin D-binding protein). α_2 -Globulin includes haptoglobin, ceruloplasmin, and α_2 -macroglobulin. β -Globulin includes transferrin, hemopexin, very-low-density lipoproteins, low-density lipoproteins, β_2 -microglobulin, fibrinogen, complement, and C-reactive protein. γ -Globulin includes immunoglobulin (Ig) G, IgA, IgM, IgD, and IgE. After an acute infection or trauma, levels of many of the liver-derived

proteins increase, whereas albumin level decreases; these conditions may not reflect an abnormal total protein determination.

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluation of edema, as seen in patients with low total protein and low albumin levels
- Evaluation of nutritional status

POTENTIAL DIAGNOSIS

Increased in

- α_1 -Globulin proteins in acute and chronic inflammatory diseases
- α_2 -Globulin proteins occasionally in diabetes, pancreatitis, and hemolysis
- β -Globulin proteins in hyperlipoproteinemias and monoclonal gammopathies
- γ -Globulin proteins in chronic liver diseases, chronic infections, autoimmune disorders, hepatitis, cirrhosis, and lymphoproliferative disorders
- Total protein:
 - Dehydration (*related to hemoconcentration*)
 - Monoclonal and polyclonal gammopathies (*related to excessive γ -globulin protein synthesis*)
 - Myeloma (*related to excessive γ -globulin protein synthesis*)

Sarcoidosis (*related to excessive γ -globulin protein synthesis*)

Some types of chronic liver disease

Tropical diseases (e.g., leprosy) (*related to inflammatory reaction*)

Waldenström's macroglobulinemia

(*related to excessive γ -globulin protein synthesis*)

Decreased in

- α_1 -Globulin proteins in hereditary deficiency
- α_2 -Globulin proteins in nephrotic syndrome, malignancies, numerous subacute and chronic inflammatory disorders, and recovery stage of severe burns
- β -Globulin proteins in hypo- β -lipoproteinemias and IgA deficiency
- γ -Globulin proteins in immune deficiency or suppression
- Total protein:
 - Administration of IV fluids (*related to hemodilution*)
 - Burns (*related to fluid retention, loss of albumin from chronic open burns*)
 - Chronic alcoholism (*related to insufficient dietary intake; diminished protein synthesis by damaged liver*)
 - Chronic ulcerative colitis (*related to poor intestinal absorption*)
 - Cirrhosis (*related to damaged liver, which cannot synthesize adequate amount of protein*)
 - Crohn's disease (*related to poor intestinal absorption*)
 - Glomerulonephritis (*related to alteration in permeability that results in excessive loss by kidneys*)
 - Heart failure (*related to fluid retention*)
 - Hyperthyroidism (*possibly related to increased metabolism and corresponding protein synthesis*)
 - Malabsorption (*related to insufficient intestinal absorption*)
 - Malnutrition (*related to insufficient intake*)
 - Neoplasms
 - Nephrotic syndrome (*related to alteration in permeability that results in excessive loss by kidneys*)
 - Pregnancy (*related to fluid retention, dietary insufficiency, increased demands of growing fetus*)

Prolonged immobilization (*related to fluid retention*)

Protein-losing enteropathies (*related to excessive loss*)

Severe skin disease

Starvation (*related to insufficient intake*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase protein levels include amino acids (if given IV), anabolic steroids, angiotensin, anticonvulsants, corticosteroids, corticotropin, furosemide, insulin, isotretinoin, levonorgestrel, oral contraceptives, progesterone, radiographic agents, and thyroid agents.
- Drugs and substances that may decrease protein levels include acetylsalicylic acid, arginine, benzene, carvedilol, citrates, floxuridine, laxatives, mercury compounds, oral contraceptives, pentastarch, phosgene, pyrazinamide, rifampin, trimethadione, and valproic acid.
- Values are significantly lower (5% to 10%) in recumbent patients.
- Hemolysis can falsely elevate results.
- Venous stasis can falsely elevate results; the tourniquet should not be left on the arm for longer than 60 sec.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing nutritional status related to disease process.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's gastrointestinal, hepatobiliary, and immune systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Educate the patient, as appropriate, that good dietary sources of complete protein (containing all eight essential amino acids) include meat, fish, eggs, and dairy products and that good sources of incomplete protein (lacking one or more of the eight essential amino acids) include grains, nuts, legumes, vegetables, and seeds.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include albumin, ALP, ACE, anion gap, AST, biopsy liver, biopsy lung, calcium, carbon dioxide, chloride, CBC WBC count and differential, cryoglobulin, fecal analysis, fecal fat, gallium scan, GGT, IgA, IgG, IgM, IFE, liver and spleen scan, magnesium, mediastinoscopy, β_2 -microglobulin, osmolality, protein urine total and fractions, PFT, radiography bone, RF, sodium, TSH, thyroxine, and UA.
- ▶ Refer to the Gastrointestinal, Hepatobiliary, and Immune systems tables at the end of the book for related tests by body system.

Protein C

SYNONYM/ACRONYM: Protein C antigen, protein C functional.

COMMON USE: To assess coagulation function and assist in diagnosis of disorders such as thrombosis and protein C deficiency.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Clot detection) 70% to 140% activity. Values are significantly reduced in children because of liver immaturity. Levels rise to approximately 50% of adult levels by age 5 yr and reach adult levels by age 16 yr.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in: N/A

Decreased in

- Congenital deficiency
- Disseminated intravascular coagulation (DIC) (*related to increased consumption*)
- Liver disease (*related to decreased synthesis by the liver*)
- Oral anticoagulant therapy (*patients deficient in protein C may be at risk of developing*

Coumadin-induced skin necrosis unless an immediate-acting anticoagulant like heparin is administered until therapeutic Coumadin levels are achieved)

- Septic shock (*related to increased consumption and decreased synthesis due to hepatic impairment*)
- Vitamin K deficiency (*related to production of dysfunctional protein in the absence of vitamin K*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

P

Protein S

SYNONYM/ACRONYM: Protein S antigen, protein S functional.

COMMON USE: To assess coagulation function, assist in the diagnosis of disorders such as disseminated intravascular coagulation (DIC), and evaluate oral anticoagulation therapy.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (3.2% sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Clot detection)

	Conventional Units
Adult	70%–140% activity
Pediatric	12%–60% activity

Note: The low end of “normal” is lower in children younger than age 16 because of the immaturity of the liver.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in: N/A

Decreased in

- Acute phase reactions (*related to increased levels of C4b-binding protein in response to inflammation, which decrease levels of available functional protein*)

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

- Congenital deficiency
- Disseminated intravascular coagulation (DIC) (*related to increased consumption*)
- Estrogen (replacement therapy, oral contraceptives, and pregnancy) (*elevated estrogen levels are associated with decreased protein levels; estrogen does not stimulate hypercoagulable states*)
- Liver disease (*related to decreased synthesis by the liver*)
- Oral anticoagulant therapy
- Vitamin K deficiency (*related to production of dysfunctional protein in the absence of vitamin K*)

CRITICAL FINDINGS: N/A

Protein, Urine: Total Quantitative and Fractions

SYNONYM/ACRONYM: None.

COMMON USE: To assess for the presence of protein in the urine toward diagnosing disorders affecting the kidneys and urinary tract, such as cancer, infection, and pre-eclampsia.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Spectrophotometry for total protein, electrophoresis for protein fractions)

	Conventional Units	SI Units (Conventional Units × 0.001)
Total protein	30–150 mg/24 hr	0.03–0.15 g/24 hr

Electrophoresis for fractionation is qualitative: No monoclonal gammopathy detected. (Urine protein electrophoresis should be ordered along with serum protein electrophoresis.)

DESCRIPTION: Most proteins, with the exception of the immunoglobulins, are synthesized and catabolized in the liver, where they are broken down into amino acids. The amino acids are converted to ammonia and ketoacids. Ammonia is converted to urea via the urea cycle. Urea is excreted in the urine.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the detection of Bence Jones proteins (light chains)
- Assist in the diagnosis of myeloma, Waldenström's macroglobulinemia, lymphoma, and amyloidosis
- Evaluate kidney function

POTENTIAL DIAGNOSIS

Increased in

- Diabetic nephropathy (*related to disease involving renal glomeruli, which increases permeability of protein*)
- Fanconi's syndrome (*related to abnormal protein deposits in the kidney, which can cause Fanconi's syndrome*)
- Heavy metal poisoning (*related to disease involving renal glomeruli, which increases permeability of protein*)
- Malignancies of the urinary tract (*tumors secrete protein into the urine*)
- Monoclonal gammopathies (*evidenced by large amounts of Bence Jones protein light chains excreted in the urine*)

- Multiple myeloma (*evidenced by large amounts of Bence Jones protein light chains excreted in the urine*)
- Nephrotic syndrome (*related to disease involving renal glomeruli, which increases permeability of protein*)
- Postexercise period (*related to muscle exertion*)
- Pre-eclampsia (*numerous factors contribute to increased permeability of the kidneys to protein*)
- Sickle cell disease (*related to increased destruction of red blood cells and excretion of hemoglobin protein*)
- Urinary tract infections (*related to disease involving renal glomeruli, which increases permeability of protein*)

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that may increase urine protein levels include acetaminophen, aminosalicylic acid, amphotericin B, ampicillin, antimony compounds, antipyrine, arsenicals, ascorbic acid, bacitracin, bismuth subsalicylate, bromate, capreomycin, captopril, carbamazepine, carbarsonone, carbenoxolone, carbutamide, cephaloglycin, cephaloridine, chlorpromazine, chlorpropamide, chlorthalidone, chrysoarobin, colistimethate, colistin, corticosteroids, cyclosporine, demeclocycline, 1,2-diaminopropane, diatrizoic acid, dihydrotachysterol, doxycycline, enalapril, gentamicin, gold, hydrogen

sulfide, iodoalphonic acid, iodopyracet, iopanoic acid, iophenoxic acid, ipodate, kanamycin, corn oil (Lipomul), lithium, mefenamic acid, melarsonyl, melarsoprol, mercury compounds, methicillin, methylbromide, mezlocillin, mitomycin, nafcillin, naphthalene, neomycin, NSAIDs, oxacillin, paraldehyde, penicillamine, penicillin, phenolphthalein, phenols, phensuximide, phosphorus, picric acid, piperacillin, plicamycin, polymyxin, probenecid, promazine, pyrazolones, quaternary ammonium compounds, radiographic agents, rifampin, sodium bicarbonate, streptokinase, sulfisoxazole, suramin, tetracyclines, thallium, thiosemicarbazones, tolbutamide, tolmetin, triethylenemelamine, and vitamin D.

- Drugs that may decrease urine protein levels include benazepril, captopril, cyclosporine, diltiazem, enalapril, fosinopril, interferon, lisinopril, losartan, lovastatin, prednisolone, prednisone, and quinapril.
- All urine voided for the timed collection period must be included in the collection, or else falsely decreased values may be obtained. Compare output records with volume collected to verify that all voids were included in the collection.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing the cause of protein in the urine.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's genitourinary and immune systems, symptoms, and results of previously

performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- ▶ Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- ▶ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health-care staff member to add to the laboratory collection container.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

Random Specimen (Collect in Early Morning)**Clean-Catch Specimen**

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling Catheter

- ▶ Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed Specimen

- ▶ Obtain a clean 3-L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- ▶ Begin the test between 6 and 8 a.m. if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the

specimen contains less than the recorded output, some urine may have been discarded, invalidating the test.

- ▶ Include on the collection container's label the amount of urine collected and test start and stop times.

General

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include amino acid screen, ACE, β_2 -microglobulin, biopsy bladder, biopsy bone marrow, bladder cancer markers, BUN, calcium, CBC, CT pelvis, CT renal, creatinine, cryoglobulin, culture urine, cytology urine, cystometry, cystoscopy, glucose, glycated hemoglobin, Hgb electrophoresis, IgA, IgG, IgM, IFE, IVP, lead, LAP, MRI musculoskeletal, microalbumin, osmolality, porphyrins, protein blood total and fractions, renogram, sickle cell screen, US bladder, US spleen, UA, and voiding cystourethrography.
- ▶ Refer to the Genitourinary and Immune systems tables at the end of the book for related tests by body system.

Prothrombin Time and International Normalized Ratio

SYNONYM/ACRONYM: Prottime, PT.

COMMON USE: To assess and monitor coagulation status related to therapeutic interventions and disorders such as vitamin K deficiency.

SPECIMEN: Plasma (1 mL) collected in a completely filled blue-top (sodium citrate) tube. If the patient's hematocrit exceeds 55%, the volume of citrate in the collection tube must be adjusted.

NORMAL FINDINGS: (Method: Clot detection) 10 to 13 sec.

- International normalized ratio (INR) = Less than 2 for patients not receiving anticoagulation therapy, 2 to 3 for patients receiving treatment for venous thrombosis, pulmonary embolism, and valvular heart disease.
- INR = 2.5 to 3.5 for patients with mechanical heart valves and/or receiving treatment for recurrent systemic embolism.

DESCRIPTION: Prothrombin time (PT) is a coagulation test performed to measure the time it takes for a firm fibrin clot to form after tissue thromboplastin (factor III) and calcium are added to a sample of plasma. Coagulation factors in the patient's sample, including prothrombin (factor II) react with the reagents and complete the process of coagulation in proportion to the amount of available coagulation factors. The PT is used to evaluate the tissue factor pathway, formerly called the extrinsic pathway of the coagulation sequence in patients receiving oral warfarin (Coumadin) anticoagulants. Prothrombin is a vitamin K-dependent protein produced by the liver; measurement is reported as time in seconds or percentage of normal activity.

The goal of long-term anticoagulation therapy is to achieve a balance between in vivo thrombus

formation and hemorrhage. It is a delicate clinical balance, and because of differences in instruments and reagents, there is a wide variation in PT results among laboratories. Worldwide concern for the need to provide more consistency in monitoring patients receiving anticoagulant therapy led to the development of an international committee. In the early 1980s, manufacturers of instruments and reagents began comparing their measurement systems with a single reference material provided by the World Health Organization (WHO). The international effort successfully developed an algorithm to provide comparable PT values regardless of differences in laboratory methodology. Reagent and instrument manufacturers compare their results to the WHO reference and derive a factor called an international sensitivity index (ISI) that is applied to a mathematical formula

to standardize the results. Laboratories convert their PT values into an international normalized ratio (INR) by using the following formula:

$$\text{INR} = (\text{patient PT result/normal patient average})^{(\text{ISI})}$$

PT evaluation can now be based on an INR using a standardized thromboplastin reagent to assist in making decisions regarding oral anticoagulation therapy.

The metabolism of many commonly prescribed medications is driven by the cytochrome P450 (CYP450) family of enzymes. Genetic variants can alter enzymatic activity that results in a spectrum of effects ranging from the total absence of drug metabolism to ultrafast metabolism. Impaired drug metabolism can prevent the intended therapeutic effect or even lead to serious adverse drug reactions. Poor metabolizers (PM) are at increased risk for drug-induced side effects due to accumulation of drug in the blood, whereas ultra-rapid metabolizers (UM) require a higher-than-normal dosage because the drug is metabolized over a shorter duration than intended. In the case of prodrugs that require activation before metabolism, the opposite occurs: PM may require a higher dose because the activated drug is becoming available more slowly than intended, and UM may require less because the activated drug is becoming available sooner than intended. Other genetic phenotypes used to report CYP450 results are intermediate metabolizer (IM) and extensive metabolizer (EM). Genetic testing can be performed on blood samples

submitted to a laboratory. The test method commonly used is polymerase chain reaction. Counseling and informed written consent are generally required for genetic testing. CYP2C9 is a gene in the CYP450 family that metabolizes prodrugs like the anticoagulant warfarin. Three major gene mutations are associated with warfarin response and are estimated to account for up to 45% of variations in Caucasians and up to 30% of variations in African Americans. The CYP450 genes are distributed differently and in predictable frequency among various ethnic groups; incidence of mutation in CYP2C9*2 allele in Caucasians is 8% to 19%, in Asians is less than 0% to 4%, and in African Americans is 0% to 12%; incidence of mutation in CYP2C9*3 allele in Caucasians is 5% to 16%, in Asians is 1% to 8%, and in African Americans is 0% to 6%; incidence of mutation in VKORC1 (as predicted by 1639G > A mutation) is 37% in Caucasians, 89% in Asians, and 14% in African Americans. CYP450 testing is available and should be used in conjunction with other factors, including all prescription and over-the-counter medications being used; mode of drug administration; use of tobacco products, foods, and supplements; age, weight, environment, activity level, and diseases with which the patient may be dealing.

Some inferences of factor deficiency can be made by comparison of results obtained from the activated partial thromboplastin time (aPTT) and PT tests. A normal aPTT with a prolonged PT can occur only with factor VII deficiency. A prolonged aPTT with a normal PT could indicate a deficiency in factors XII, XI, IX, and

VIII as well as VIII:C (von Willebrand factor). Factor deficiencies can also be identified by correction or substitution studies using normal serum. These studies are easy to perform and are accomplished by adding plasma from a healthy patient to a sample from a suspected factor-deficient patient. When the PT is repeated and corrected, or within the reference range, it can be assumed that the prolonged PT is due to a factor deficiency (see monograph titled “Coagulation Factors”). If the result remains uncorrected, the prolonged PT is most likely due to a circulating anticoagulant.

This procedure is contraindicated for: N/A

INDICATIONS

- Differentiate between deficiencies of clotting factors II, V, VII, and X, which prolong the PT, and congenital coagulation disorders such as hemophilia A (factor VIII) and hemophilia B (factor IX), which do not alter the PT
- Evaluate the response to anticoagulant therapy with coumadin derivatives and determine dosage required to achieve therapeutic results
- Identify individuals who may be prone to bleeding during surgical, obstetric, dental, or invasive diagnostic procedures
- Identify the possible cause of abnormal bleeding, such as epistaxis, hematoma, gingival bleeding, hematuria, and menorrhagia
- Monitor the effects of conditions such as liver disease, protein deficiency, and fat malabsorption on hemostasis
- Screen for prothrombin deficiency
- Screen for vitamin K deficiency

POTENTIAL DIAGNOSIS

Increased in

- Afibrinogenemia, dysfibrinogenemia, or hypofibrinogenemia (*related to insufficient levels of fibrinogen, which is required for clotting; its absence prolongs PT*)
- Biliary obstruction (*related to poor absorption of fat-soluble vitamin K; vitamin K is required for clotting and its absence prolongs PT*)
- Disseminated intravascular coagulation (*related to increased consumption of clotting factors; PT is increased*)
- Hereditary deficiencies of factors II, V, VII, and X (*related to deficiency of factors required for clotting; their absence prolongs PT*)
- Liver disease (cirrhosis) (*related to decreased liver function, which results in decreased production of clotting factors and prolonged PT*)
- Massive transfusion of packed red blood cells (RBCs) (*related to dilutional effect of replacing a significant fraction of the total blood volume; there are insufficient clotting factors in plasma-poor, packed RBC products. Blood products contain anticoagulants, which compound the lack of adequate clotting factors in the case of massive transfusion*)
- Poor fat absorption (*tropical sprue, celiac disease, and chronic diarrhea are conditions that prevent absorption of fat-soluble vitamins, including vitamin K, which is required for clotting; its absence prolongs PT*)
- Presence of circulating anticoagulant (*related to the production of inhibitors of specific factors, e.g., developed from long-term factor VIII therapy or circulating anticoagulants associated with conditions like tuberculosis, systemic lupus erythematosus, rheumatoid*

arthritis, and chronic glomerulonephritis)

- Salicylate intoxication (*related to decreased liver function*)
- Vitamin K deficiency (*vitamin K is required for clotting; its absence prolongs PT*)

Decreased in

- Ovarian hyperfunction
- Regional enteritis or ileitis

CRITICAL FINDINGS

INR

- Greater than 5

Prothrombin Time

- Greater than 27 sec

Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Important signs to note relate to bleeding in specific areas of the body and include prolonged bleeding from cuts or gums, hematoma at a puncture site, hemorrhage, blood in the stool, backache or flank pain, dark colored urine, joint pain, persistent epistaxis, heavy or prolonged menstrual flow, and shock. Monitor vital signs, unusual ecchymosis, occult blood, severe headache, unusual dizziness, and neurological changes until PT is within normal range. Intramuscular (IM) administration of vitamin K, an anticoagulant reversal agent, may be requested by the HCP.

INTERFERING FACTORS

- Drugs that may increase the PT in patients receiving anticoagulation therapy include acetaminophen, acetylsalicylic acid, amiodarone, anabolic steroids, anisindione, anistreplase, antibiotics, antipyrine, carbenicillin, cathartics, chloral hydrate, chlorthalidone, cholestyramine, clofibrate, corticotropin, demeclocycline, dextrothyroxine, diazoxide, diflunisal, disulfiram, diuretics, doxycycline, erythromycin, ethyl alcohol, hydroxyzine, laxatives, mercaptopurine, miconazole, nalidixic acid, neomycin, niacin, oxyphenbutazone, phenytoin, quinidine, quinine, sulfachlorpyridazine, thyroxine, and tosylate bretylium.
- Drugs that may decrease the PT in patients receiving anticoagulation therapy include aminoglutethimide, amobarbital, anabolic steroids, antacids, antihistamines, barbiturates, carbamazepine, chloral hydrate, chlordane, chlordinazepoxide, cholestyramine, clofibrate, colchicine, corticosteroids, dichloralphenazone, diuretics, oral contraceptives, penicillin, primidone, raloxifene, rifabutin, rifampin, simethicone, spironolactone, tacrolimus, tolbutamide, and vitamin K.

- Traumatic venipunctures can activate the coagulation sequence by contaminating the sample with tissue thromboplastin and producing falsely shortened PT.
- Hematocrit greater than 55% may cause falsely prolonged results because of anticoagulant excess relative to plasma volume.
- Incompletely filled collection tubes, specimens contaminated with heparin, clotted or hemolyzed specimens, or unprocessed specimens not delivered to the laboratory within 24 hr of collection should be rejected.
- Excessive agitation causing sample hemolysis can falsely shorten the PT because the hemolyzed cells activate plasma-clotting factors.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Bleeding (<i>Related to alerted clotting factors secondary to warfarin use or depleted clotting factors</i>)	Altered level of consciousness; hypotension; increased heart rate; decreased HGB and HCT; capillary refill greater than 3 sec; cool extremities; blood in urine, stool, sputum; bleeding gums; nosebleed; bruises easily	Increase frequency of vital sign assessment with variances in results; monitor for vital sign trends; administer blood or blood products as ordered; administer prescribed vitamin K; monitor and trend HGB/HCT; assess skin for petechiae, purpura, hematoma; monitor for blood in emesis, or sputum; institute bleeding precautions (prevent unnecessary venipuncture; avoid IM injections; prevent trauma; be gentle with oral care, suctioning; avoid use of a sharp razor); administer prescribed stool softener; monitor and trend PT/INR in relation to warfarin dosage
Gas exchange (<i>Related to deficient oxygen capacity of the blood secondary to blood loss</i>)	Irregular breathing pattern, use of accessory muscles; altered chest excursion; adventitious breath sounds (crackles, rhonchi, wheezes, diminished breath	Monitor respiratory rate and effort based on assessment of patient condition; assess lung sounds frequently; monitor for secretions, bloody sputum; suction as necessary; use pulse oximetry to monitor oxygen saturation; collaborate with

(table continues on page 1324)

Problem	Signs & Symptoms	Interventions
	sounds); copious secretions; signs of hypoxia; altered blood gas results; confusion; lethargy; cyanosis	physician to administer oxygen as needed; elevate the head of the bed 30 degrees or higher; monitor IV fluids and avoid aggressive fluid resuscitation; assess level of consciousness; anticipate the need for possible intubation
Tissue perfusion <i>(Related to decreased hemoglobin secondary to bleeding; altered clotting factors)</i>	Hypotension; dizziness; cool extremities; pallor; capillary refill greater than 3 sec in fingers and toes; weak pedal pulses; altered level of consciousness; altered sensation	Monitor blood pressure; assess for dizziness; assess extremities for skin temperature, color, warmth; assess capillary refill; assess pedal pulses; monitor for numbness, tingling, hyperesthesia, hypoesthesia; monitor and trend PT and INR; administer blood or blood products as ordered; administer vitamin K as ordered; administer IV fluids as ordered; use fluid bolus as appropriate; administer medication to support blood pressure as ordered
Health management <i>(Related to inaccurate self-medication of warfarin; complexity of health-care system; complexity of therapeutic management; knowledge deficit; cultural family health patterns; mistrust of health-care provider)</i>	Inability or failure to recognize or process information toward improving health and preventing illness with associated mental and physical effects	Collaborate with health-care provider to develop a plan of care that supports health; ensure patient adheres to recommended medication regime; encourage patient to comply with health-care follow-up appointments

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating coagulation and monitor therapy.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, hematopoietic, and hepatobiliary systems, especially any bleeding disorders and other symptoms, as well as results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in

Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture. Fill tube completely. *Important note:* When multiple specimens are drawn, the blue-top tube should be collected after sterile (i.e., blood culture) tubes. Otherwise, when using a standard vacutainer system, the blue-top tube is the first tube collected. When a butterfly is used and due to the added tubing, an extra red-top tube should be collected before the blue-top tube to ensure complete filling of the blue-top tube.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis. If delays in specimen transport and processing occur, it is important to consult with the testing laboratory. Whole blood specimens are stable at room temperature for up to 24 hr. Some laboratories will accept refrigerated whole blood samples up to 48 hr from the time of collection. Criteria for rejection of specimens based on collection time may vary among facilities.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Frequent monitoring of the PT/INR is very important. Concern with monitoring is mostly involved with elevated values. However, decreased PT results can indicate a risk for thrombosis. There are three factors, known as Virchow's triad, that increase the risk of developing a venous thrombus:
 - ▶ Hypercoagulability, or a tendency for blood to coagulate at an abnormally rapid rate

- ▶ Venous stasis, or an impaired rate of blood flow through a vessel
 - ▶ Vessel wall trauma or injury
- Possible nursing interventions to decrease risk of thrombus include education for the patient regarding leg exercises, avoidance of constrictive clothing (e.g., stockings or tight socks), or avoidance of behaviors that might constrict blood flow, such as crossing of the legs or maintaining a dependent position for long periods of time.

▶ **Nutritional Considerations:** Foods high in vitamin K should be avoided by the patient on anticoagulant therapy. Foods that contain vitamin K include cabbage, cauliflower, chickpeas, egg yolks, green tea, pork, liver, milk, soybean products, tomatoes, mayonnaise, vegetable oils, and green leafy vegetables such as leaf lettuce, watercress, parsley, broccoli, brussels sprouts, kale, spinach, and turnip greens.

▶ **Nutritional Considerations:** Avoid alcohol and alcohol products while taking warfarin because the combination of the two increases the risk of gastrointestinal bleeding.

▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Instruct the patient to report bleeding from any areas of the skin or mucous membranes.
- ▶ Inform the patient with prolonged PT/INR of the importance of taking precautions against bruising and bleeding, including the use of a soft bristle toothbrush, use of an electric razor, avoidance of constipation, avoidance of aspirin products, and avoidance of IM injections.
- ▶ Inform the patient of the importance of periodic laboratory testing while taking an anticoagulant.

- ▶ Reinforce the importance of refraining from alcohol use while on warfarin.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Instruct the patient in the use of home test kits for PT/INR approved by the U.S. Food and Drug Administration, as appropriate.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States signs and symptoms of bleeding that should be reported to the HCP
- ▶ States understanding of the benefit of taking warfarin to the patient's overall health

Skills

- ▶ Demonstrates proficiency and accuracy in the self-administration of warfarin
- ▶ Identifies foods high in vitamin K and includes them in the diet

Attitude

- ▶ Discusses barriers to compliance with therapeutic management and makes efforts to adhere to recommendations
- ▶ Complies with recommended follow-up appointments for PT and INR evaluation

RELATED MONOGRAPHS:

- ▶ Related tests include, ALP, ALT, ANA, AT-III, AST, bilirubin, biopsy liver, bleeding time, calcium, coagulation factors, CBC, CBC platelet count, CT liver and biliary tract, cryoglobulin, D-dimer, fecal analysis, fecal fat, FDP, fibrinogen, GGT, gastric acid emptying scan, hepatitis antibodies (A, B, C, D), liver and spleen scan, lupus anticoagulant, aPTT, plasminogen, protein C, protein S, US abdomen, US liver, and vitamin K.
- ▶ Refer to the Cardiovascular, Hematopoietic, and Hepatobiliary systems tables at the end of the book for related tests by body system.

Pseudocholinesterase and Dibucaine Number

SYNONYM/ACRONYM: CHS, PCHE, AcCHS.

COMMON USE: To assess for pseudocholinesterase deficiency to assist in diagnosing a congenital deficiency. Special attention must be given to results for preoperative patients because positive results indicate risk for apnea with use of succinylcholine as an anesthetic agent.

SPECIMEN: Plasma (1 mL) collected in a lavender-top (EDTA) tube. Serum (1 mL) collected in a red-top tube is also acceptable.

NORMAL FINDINGS: (Method: Spectrophotometry, kinetic)

Test	Conventional Units
Pseudocholinesterase	
Males	3,334–7,031 IU/L
Females	2,504–6,297 IU/L

Dibucaine Number	Fraction (%) of Activity Inhibited
Normal homozygote	79%–84%
Heterozygote	55%–70%
Abnormal homozygote	16%–28%

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Increased levels are observed in a number of conditions without specific cause.

- Diabetes
- Hyperthyroidism
- Nephrotic syndrome
- Obesity

Decreased in

The enzyme is produced in the liver, and any condition affecting liver function may result in decreased production of circulating enzyme.

- Acute infection
- Anemia (severe)

- Carcinomatosis
- Cirrhosis
- Congenital deficiency
- Hepatic carcinoma
- Hepatocellular disease
- Infectious hepatitis
- Insecticide exposure (*organic phosphate exposure decreases enzyme activity*)
- Malnutrition (*possibly related to decreased availability of transport proteins; condition associated with decreased enzyme activity*)
- Muscular dystrophy
- Myocardial infarction
- Plasmapheresis (*iatrogenic cause*)
- Succinylcholine hypersensitivity (*this chemical is a trigger in susceptible individuals*)

- Tuberculosis (*chronic infection is known to decrease enzyme activity*)
- Uremia (*pathological condition known to decrease enzyme activity*)

CRITICAL FINDINGS

A positive result indicates that the patient is at risk for prolonged or

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

unrecoverable apnea related to the inability to metabolize succinylcholine. Note and immediately report to the health-care provider (HCP) any critically increased values and related symptoms.

Notify the anesthesiologist if the test result is positive and surgery is scheduled.

Pulmonary Function Studies

SYNONYM/ACRONYM: Pulmonary function tests (PFTs).

COMMON USE: To assess respiratory function to assist in evaluating obstructive versus restrictive lung disease and to monitor and assess the effectiveness of therapeutic interventions.

AREA OF APPLICATION: Lungs, respiratory system.

CONTRAST: None.

DESCRIPTION: Pulmonary function studies provide information about the volume, pattern, and rates of airflow involved in respiratory function. These studies may also include tests involving the diffusing capabilities of the lungs (i.e., volume of gases diffusing across a membrane). A complete pulmonary function study includes the determination of all lung volumes, spirometry, diffusing capacity, maximum voluntary ventilation, flow-volume loop, and maximum expiratory and inspiratory pressures (See Figure 1 showing lung volumes measured during PFT).

Other studies include small airway volumes.

Pulmonary function studies are classified according to lung volumes and capacities, rates of flow, and gas exchange. The exception is the diffusion test, which records the movement of a gas during inspiration and expiration. Lung volumes and capacities constitute the amount of air inhaled or exhaled from the lungs; this value is compared to normal reference values specific for the patient's age, height, and gender. The following are volumes and capacities measured by spirometry that do not require timed testing.

Tidal Volume	TV	Total amount of air inhaled and exhaled with one breath
Residual Volume	RV	Amount of air remaining in the lungs after a maximum expiration effort; this indirect type of measurement can be done by body plethysmography (see monograph titled "Plethysmography")
Inspiratory reserve volume	IRV	Maximum amount of air inhaled at the point of maximum expiration
Expiratory reserve volume	ERV	Maximum amount of air exhaled after a resting expiration; can be calculated by the vital capacity (VC) minus the inspiratory capacity (IC)
Vital capacity	VC	Maximum amount of air exhaled after a maximum inspiration (can be calculated by adding the IC and the ERV)
Total lung capacity	TLC	Total amount of air that the lungs can hold after maximum inspiration; can be calculated by adding the vital capacity (VC) and the residual volume (RV)
Inspiratory capacity	IC	Maximum amount of air inspired after normal expiration; can be calculated by adding the inspiratory reserve volume (IRV) and the tidal volume (TV)
Functional residual capacity	FRC	Volume of air that remains in the lungs after normal expiration can be calculated by adding the residual volume (RV) and expiratory reserve volume (ERV)

The volumes, capacities, and rates of flow measured by spirometry that do require timed testing include the following:

Forced vital capacity in 1 sec	FEV1	Maximum amount of air that can be forcefully exhaled after a full inspiration
Forced expiratory volume	FEV	Amount of air exhaled in the first second (can also be determined at 2 or 3 sec) of forced vital capacity (FVC), which is the amount of air exhaled in seconds, expressed as a percentage
Maximal midexpiratory flow	MMEF	Also known as forced expiratory flow rate (FEF_{25-75}), or the maximal rate of airflow during a forced expiration
Forced inspiratory flow rate	FIF	Volume inspired from the RV at a point of measurement (can be expressed as a percentage to identify the corresponding volume pressure and inspired volume)

(table continues on page 1330)

Peak inspiratory flow rate	PIFR	Maximum airflow during a forced maximal inspiration
Peak expiratory flow rate	PEFR	Maximum airflow expired during FVC
Flow-volume loops	F-V	Flows and volumes recorded during forced expiratory volume and forced inspiratory VC procedures
Maximal inspiratory-expiratory pressures		Strengths of the respiratory muscles in neuromuscular disorders
Maximal voluntary ventilation	MVV	Maximal volume of air inspired and expired in 1 min (may be done for shorter periods and multiplied to equal 1 min)

Other studies for gas-exchange capacity, small airway abnormalities, and allergic responses in hyperactive airway disorders can be performed during the conventional pulmonary function study. These include the following:

Diffusing capacity of the lungs	DL	Rate of transfer of carbon monoxide through the alveolar and capillary membrane in 1 min
Closing volume	CV	Measure of the closure of small airways in the lower alveoli by monitoring volume and percentage of alveolar nitrogen after inhalation of 100% oxygen
Isoflow volume	isoV	Flow-volume loop test followed by inhalation of a mixture of helium and oxygen to determine small airway disease
Body plethysmography		Measure of thoracic gas volume and airway resistance
Bronchial provocation		Quantification of airway response after inhalation of methacholine
Arterial blood gases	ABGs	Measure of oxygen, pH, and carbon dioxide in arterial blood

Values are expressed in units of mL, %, L, L/sec, and L/min, depending on the test performed.

Note: See figure 1 showing some examples of PFT results presented in graphic form; the graphs assist in interpreting the findings and establishing the diagnosis of respiratory conditions.

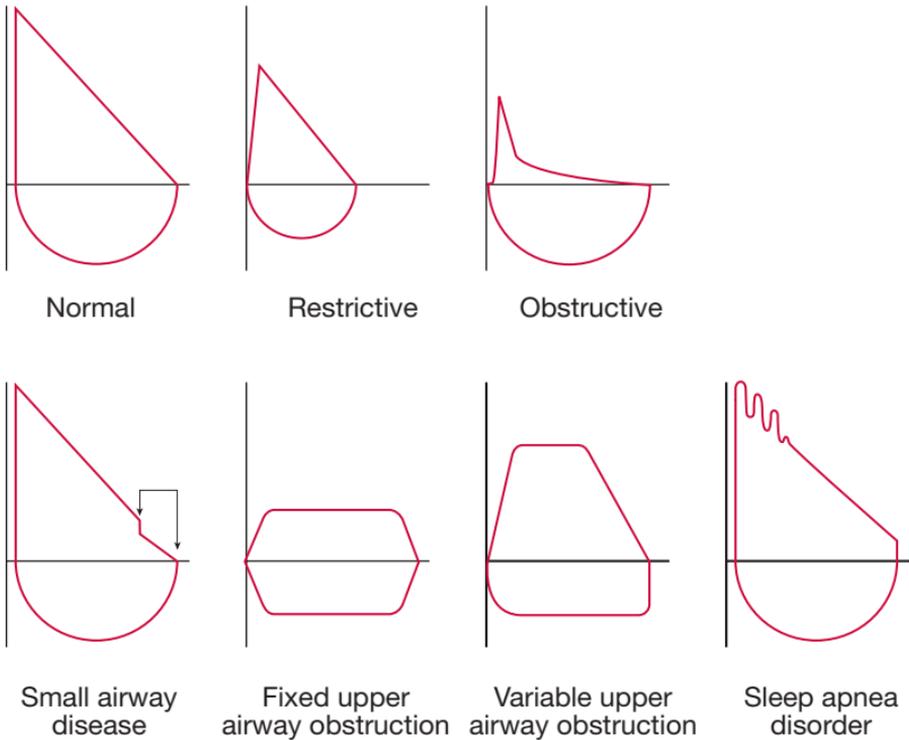

Figure 1 Examples of PFT results presented in graphic form.

This procedure is contraindicated for

- Patients with cardiac insufficiency, recent myocardial infarction, and presence of chest pain that affects inspiration or expiration ability.

INDICATIONS

- Detect chronic obstructive pulmonary disease (COPD) and/or restrictive pulmonary diseases that affect the chest wall (e.g., neuromuscular disorders, kyphosis, scoliosis) and lungs, as evidenced by abnormal airflows and volumes
- Determine airway response to inhalants in patients with an airway-reactive disorder
- Determine the diffusing capacity of the lungs (DCOL)
- Determine the effectiveness of therapy regimens, such as bronchodilators, for pulmonary disorders
- Determine the presence of lung disease when other studies, such as x-rays, do not provide a definitive diagnosis, or determine the progression and severity of known COPD and restrictive pulmonary disease
- Evaluate the cause of dyspnea occurring with or without exercise
- Evaluate lung compliance to determine changes in elasticity, as evidenced by changes in lung volumes (decreased in restrictive pulmonary disease, increased in COPD and in elderly patients)
- Evaluate pulmonary disability for legal or insurance claims
- Evaluate pulmonary function after surgical pneumonectomy, lobectomy, or segmental lobectomy
- Evaluate the respiratory system to determine the patient's ability to

tolerate procedures such as surgery or diagnostic studies

- Screen high-risk populations for early detection of pulmonary conditions (e.g., patients with exposure to occupational or environ-

mental hazards, smokers, patients with a hereditary predisposition)

POTENTIAL DIAGNOSIS

Normal adult lung volumes, capacities, and flow rates are as follows:

TV	500 mL at rest
RV	1,200 mL (approximate)
IRV	3,000 mL (approximate)
ERV	1,100 mL (approximate)
VC	4,600 mL (approximate)
TLC	5,800 mL (approximate)
IC	3,500 mL (approximate)
FRC	2,300 mL (approximate)
FVC	3,000–5,000 mL (approximate)
FEV ₁ /FVC	81%–83%
MMEF	25%–75%
FIF	25%–75%
MVV	25%–35% or 170 L/min
PIFR	300 L/min
PEFR	450 L/min
F-V loop	Normal curve
DCOL	25 mL/min per mm Hg (approximate)
CV	10%–20% of VC
V _{iso}	Based on age formula
Bronchial provocation	No change, or less than 20% reduction in FEV ₁

Note: Normal values listed are estimated values for adults. Actual pediatric and adult values are based on age, height, and gender. These normal values are included on the patient's pulmonary function laboratory report. CV = closing volume; DCOL = diffusing capacity of the lungs; ERV = expiratory reserve volume; FEV₁ = forced expiratory volume in 1 sec; FIF = forced inspiratory flow rate; FRC = functional residual capacity; FVC = forced vital capacity in 1 second; F-V loop = flow-volume loop; IC = inspiratory capacity; IRV = inspiratory reserve volume; MMEF = maximal midexpiratory flow (also known as FEF₂₅₋₇₅); MVV = maximal voluntary ventilation; PEFR = peak expiratory flow rate; PIFR = peak inspiratory flow rate; RV = residual volume; TLC = total lung capacity; TV = tidal volume; VC = vital capacity; V_{iso} = isoflow volume. (See figure 2)

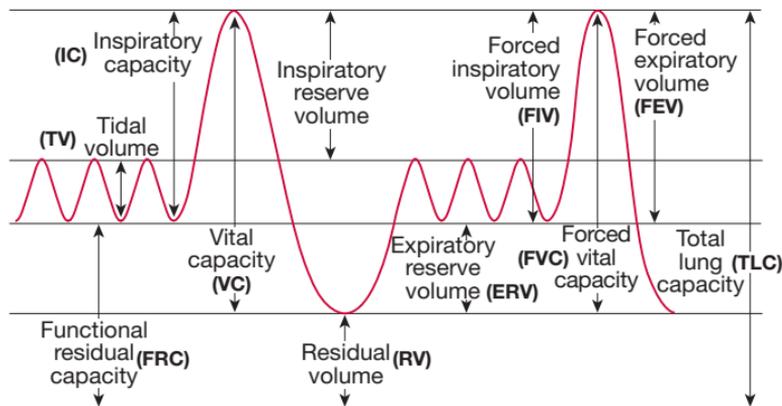

Figure 2 showing lung volumes measured during PFT.

Normal findings in

- Normal respiratory volume and capacities, gas diffusion, and distribution
- No evidence of COPD or restrictive pulmonary disease

Abnormal findings in

- Allergy
- Asbestosis
- Asthma
- Bronchiectasis
- Chest trauma
- Chronic bronchitis
- Curvature of the spine
- Emphysema
- Myasthenia gravis
- Obesity
- Pulmonary fibrosis
- Pulmonary tumors
- Respiratory infections
- Sarcoidosis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- The aging process can cause decreased values (FVC, DCOL) depending on the study done.
- Inability of the patient to put forth the necessary breathing effort affects the results.
- Medications such as bronchodilators can affect results.
- Improper placement of the nose clamp or mouthpiece that allows for leakage can affect volume results.
- Confusion or inability to understand instructions or cooperate during the study can cause inaccurate results.
- Exercise caution with patients who have upper respiratory infections, such as a cold or acute bronchitis.

NURSING IMPLICATIONS AND PROCEDURE**PRETEST:**

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing lung function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no discomfort will be experienced during the test. Explain that the procedure is generally performed in a specially equipped room or in a health-care provider's (HCP's) office by an HCP specializing in this procedure and usually lasts 1 hr.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Record the patient's height and weight.
- ▶ Instruct the patient to avoid bronchodilators (oral or inhalant) for at least 4 hr before the study, as directed by the HCP.
- ▶ Instruct the patient to refrain from smoking tobacco or eating a heavy meal for 4 to 6 hr prior to the study. Protocols may vary among facilities.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure the patient has complied with dietary and medication restrictions and pretesting preparations.
- ▶ Obtain an inhalant bronchodilator to treat any bronchospasms that may occur with testing.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to void and to loosen any restrictive clothing.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Place the patient in a sitting position on a chair near the spirometry equipment.
- ▶ Place a soft clip on the patient's nose to restrict nose breathing, and instruct the patient to breathe through the mouth.
- ▶ Place a mouthpiece in the mouth and instruct the patient to close his or her lips around it to form a seal.
- ▶ Tubing from the mouthpiece attaches to a cylinder that is connected to a computer that measures, records, and calculates the values for the tests done.
- ▶ Instruct the patient to inhale deeply and then to quickly exhale as much air as possible into the mouthpiece.
- ▶ Additional breathing maneuvers are performed on inspiration and expiration (normal, forced, and breath-holding).

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Assess the patient for dizziness or weakness after the testing.

- ▶ Allow the patient to rest as long as needed to recover.
- ▶ Instruct the patient to resume usual diet and medications, as directed by the HCP. Inform the patient of smoking cessation programs as appropriate.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include α_1 -AT, anion gap, arterial/alveolar oxygen ratio, biopsy lung, blood gases, bronchoscopy, carboxyhemoglobin, chest x-ray, chloride sweat, CBC, CBC hemoglobin, CBC WBC count and differential, CT angiography, CT thoracic, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, echocardiography, ECG, Gram stain, IgE, lactic acid, lung perfusion scan, lung ventilation scan, MR angiography, MRI chest, osmolality, phosphorus, plethysmography, pleural fluid analysis, potassium, PET chest, pulse oximetry, sodium, and TB skin test.
- ▶ Refer to the Cardiovascular and Respiratory systems tables at the end of the book for related tests by body system.

Pulse Oximetry

SYNONYM/ACRONYM: Oximetry, pulse ox.

COMMON USE: To assess arterial blood oxygenation toward evaluating respiratory status during ventilation, acute illness, activity, and sleep and to evaluate the effectiveness of therapeutic interventions.

AREA OF APPLICATION: Earlobe, fingertip; for infants, use the large toe, top or bottom of the foot, or sides of the ankle.

CONTRAST: None.

DESCRIPTION: Pulse oximetry is a noninvasive study that provides continuous readings of arterial blood oxygen saturation (SpO_2) using a sensor site (earlobe or fingertip). The SpO_2 equals the ratio of the amount of O_2 contained in the hemoglobin to the maximum amount of O_2 contained, with hemoglobin expressed as a percentage. The results obtained may compare favorably with O_2 saturation levels obtained by arterial blood gas analysis without the need to perform successive arterial punctures. The device used is a clip or probe that produces a light beam with two different wavelengths on one side. A sensor on the opposite side measures the absorption of each of the wavelengths of light to determine the O_2 saturation reading. The displayed result is a ratio, expressed as a percentage, between the actual O_2 content of the hemoglobin and the potential maximum O_2 -carrying capacity of the hemoglobin.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine the effectiveness of pulmonary gas exchange function
- Evaluate suspected nocturnal hypoxemia in chronic obstructive pulmonary disease
- Monitor oxygenation during testing for sleep apnea
- Monitor oxygenation perioperatively and during acute illnesses
- Monitor oxygenation status in patients on a ventilator, during surgery, and during bronchoscopy
- Monitor O_2 saturation during activities such as pulmonary exercise stress testing or pulmonary rehabilitation exercises to determine optimal tolerance
- Monitor response to pulmonary drug regimens, especially flow and O_2 content

POTENTIAL DIAGNOSIS

Normal findings in

- Greater than or equal to 95%

Abnormal findings in

- Abnormal gas exchange
- Hypoxemia with levels less than 95%
- Impaired cardiopulmonary function

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Patients who smoke or have suffered carbon monoxide inhalation, because O₂ levels may be falsely elevated.

Factors that may result in incorrect values

- Patients with anemic conditions reflecting a reduction in hemoglobin, the O₂-carrying component in the blood.
- Excessive light surrounding the patient, such as from surgical lights.
- Impaired cardiopulmonary function.
- Lipid emulsion therapy and presence of certain dyes.
- Movement of the finger or ear or improper placement of probe or clip.
- Nail polish, artificial fingernails, and skin pigmentation when a finger probe is used.
- Vasoconstriction from cool skin temperature, drugs, hypotension, or vessel obstruction causing a decrease in blood flow.

Other considerations

- Accuracy for most units is plus or minus 4% with a standard deviation of 1%.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in monitoring oxygen in the blood.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular and respiratory systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that no pain is associated with the procedure. Inform the patient that the procedure is generally performed at the bedside, in the operating room during a surgical procedure, or in the office of a health-care provider (HCP). Explain that the procedure lasts as long as the monitoring is needed and could be continuous.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ If a finger probe is used, instruct the patient to remove artificial fingernails and nail polish.
- ▶ When used in the presence of flammable gases, the equipment must be approved for that specific use.
- ▶ Instruct the patient not to smoke for 24 hr before the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with pretesting instructions.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ If a finger probe is used, instruct the patient not to grip treadmill rail or bed rail tightly; doing so restricts blood flow.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Massage or apply a warm towel to the upper earlobe or finger to increase the blood flow.
- ▶ The index finger is normally used, but if the patient's finger is too large for the probe, a smaller finger can be used.
- ▶ If the earlobe is used, make sure good contact is achieved.

- ▶ The big toe, top or bottom of the foot, or sides of the heel may be used in infants.
- ▶ Place the photodetector probe over the finger in such a way that the light beams and sensors are opposite each other. Turn the power switch to the oximeter monitor, which will display information about heart rate and peripheral capillary saturation (SaO_2).
- ▶ Remove the clip used for monitoring when the procedure is complete.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Closely observe SpO_2 , and report to the HCP if it decreases to 90%.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.

Answer any questions or address any concerns voiced by the patient or family.

- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include α_1 -AT, anion gap, arterial/alveolar oxygen ratio, biopsy lung, blood gases, bronchoscopy, carboxyhemoglobin, chest x-ray, chloride sweat, CBC, CBC hemoglobin, CBC WBC count and differential, CT angiography, culture and smear for mycobacteria, culture bacterial sputum, culture viral, cytology sputum, ECG, Gram stain, IgE, lactic acid, lung perfusion scan, lung ventilation scan, MR angiography, MR chest, osmolality, phosphorus, plethysmography, pleural fluid analysis, potassium, pulmonary function tests, sodium, and TB skin test.
- ▶ Refer to the Cardiovascular and Respiratory systems tables at the end of the book for related tests by body system.

Pyruvate Kinase

SYNONYM/ACRONYM: PK.

COMMON USE: To assess for an enzyme deficiency to assist in diagnosis of hemolytic anemia.

SPECIMEN: Whole blood collected in yellow-top (acid-citrate-dextrose [ACD]) tube. Specimens collected in a lavender-top (EDTA) or green-top (heparin) tube also may be acceptable in some laboratories.

NORMAL FINDINGS: (Method: Spectrophotometry) 6 to 19 micromol $\text{NAD(H)}_2/\text{min/g}$ hemoglobin (37°C).

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

Related to release of skeletal and cardiac specific isoenzymes of PK from damaged tissue cells.

- Carriers of Duchenne's muscular dystrophy
- Muscle disease
- Myocardial infarction

Decreased in

- Hereditary pyruvate kinase deficiency (evidenced by autosomal

recessive trait for PK enzyme deficiency):
Congenital nonspherocytic hemolytic anemia

- Acquired pyruvate kinase deficiency (related to interaction of medications used for therapy; related to release of leukocyte specific isoenzymes from damaged leukocytes):
Acute leukemia
Aplasias
Other anemias

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Radioactive Iodine Uptake

SYNONYM/ACRONYM: RAIU, thyroid uptake.

COMMON USE: To assess thyroid function toward diagnosing disorders such as hyperthyroidism and goiter.

AREA OF APPLICATION: Thyroid.

CONTRAST: Oral radioactive iodine.

DESCRIPTION: Radioactive iodine uptake (RAIU) is a nuclear medicine study used for evaluating thyroid function. It directly measures the ability of the thyroid gland to concentrate and retain circulating iodide for the synthesis of thyroid hormone. RAIU assists in the diagnosis of both hyperthyroidism and hypothyroidism, but it is more useful in the diagnosis of hyperthyroidism.

A very small dose of radioactive iodine-123 (I-123) or I-131 is administered orally, and images are taken at specified intervals after the initial dose is administered. The radionuclide emits gamma radiation, which allows external measurement. The uptake of radionuclide in the thyroid gland is measured as the percentage of radionuclide absorbed in a specific amount of time. The iodine not used is excreted in the urine. The thyroid gland does not distinguish between radioactive and nonradioactive iodine. Uptake values are used in conjunction with measurements of circulating thyroid hormone levels to differentiate primary and secondary thyroid disease, and serial measurements are helpful in long-term management of thyroid disease and its treatment.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant,

unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Evaluate hyperthyroidism and/or hypothyroidism
- Evaluate neck pain
- Evaluate the patient as part of a complete thyroid evaluation for symptomatic patients (e.g., swollen neck, neck pain, extreme sensitivity to heat or cold, jitters, sluggishness)
- Evaluate thyroiditis, goiter, or pituitary failure
- Monitor response to therapy for thyroid disease

POTENTIAL DIAGNOSIS

Normal findings in

- Variations in normal ranges of iodine uptake can occur with differences in dietary intake, geographic location, and protocols among laboratories:

Iodine Uptake	Percentage of Radionuclide
2-hr absorption	1%–13%
6-hr absorption	2%–25%
24-hr absorption	15%–45%

Abnormal findings in

- Decreased iodine intake or increased iodine excretion
- Graves' disease
- Iodine-deficient goiter

- Hashimoto's thyroiditis (early)
- Hyperthyroidism, increased uptake of radionuclide:

Rebound thyroid hormone withdrawal
 Drugs and hormones such as barbiturates, diuretics, estrogens, lithium carbonate, phenothiazines, and thyroid-stimulating hormone

- Hypothyroidism, decreased uptake of 0% to 10% radionuclide over 24-hr period:
 Hypoalbuminemia
 Malabsorption
 Renal failure
 Subacute thyroiditis
 Thyrotoxicosis as a result of ectopic thyroid metastasis

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Recent use of iodinated contrast medium for radiographic studies (within the last 4 wk) or nuclear medicine procedures done within the previous 24 to 48 hr.
- Iodine deficiency (e.g., patients with inadequate dietary intake, patients on phenothiazine therapy), which can increase radionuclide uptake.
- Certain drugs and other external sources of excess iodine, which can decrease radionuclide uptake, as follows:

Foods containing iodine (e.g., iodized salt)
 Drugs such as aminosalicic acid, antihistamines, antithyroid medications (e.g., propylthiouracil, iodothiouracil), corticosteroids, cough syrup, isoniazid, levothyroxine sodium/T₄, L-triiodothyronine, Lugol's solution, nitrates, penicillins, potassium iodide, propylthiouracil, saturated solution of potassium iodide, sulfonamides, thiocyanate, thyroid extract, tolbutamide, warfarin, multivitamins containing minerals

- Vomiting, severe diarrhea, and gastroenteritis, which can affect absorption of the oral radionuclide dose.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.
- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric Considerations** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing thyroid function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using iodine-based contrast medium.
- ▶ Ensure that this procedure is performed before all radiographic procedures using iodinated contrast medium.

- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Inform the patient that the procedure is performed in a nuclear medicine department by an HCP who specializes in this procedure, with support staff, and takes approximately 15 to 30 min. Delayed images or data collection is needed 24 hr later.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined.
- ▶ Instruct the patient to fast and restrict fluids for 8 to 12 hr before the procedure. The patient may eat 4 hr after the injection unless otherwise indicated. Protocols may vary among facilities.

INTRATEST:

Potential Complications:

- Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
 - ▶ Ensure the patient has complied with dietary, fluid, and medication restrictions for 8 to 12 hr before the procedure.
 - ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.
 - ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
 - ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the

- patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Administer the I-123 orally (pill form).
- ▶ Place the patient in a sitting or supine position in front of a radionuclide detector at 2, 6, and 24 hr after ingestion for uptake images.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, as directed by the HCP.
- ▶ Advise patient to drink increased amounts of fluids for 24 hr to eliminate the radionuclide from the body, unless contraindicated. Tell the patient that radionuclide is eliminated from the body within 24 to 48 hr.
- ▶ If a woman who is breastfeeding must have a nuclear scan, she should not breastfeed the infant until the radionuclide has been eliminated. This could take as long as 3 days. She should be instructed to express the milk and discard it during the 3-day period to prevent cessation of milk production.
- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash hands after the gloves are removed.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the

need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▶ Related tests include ACTH, albumin, ACE, antibodies antithyroglobulin, biopsy thyroid, BUN, CT spine, copper, creatinine, cystoscopy, fecal analysis,

fecal fat, FSH, gastric emptying scan, GH, LH, PTH, protein, thyroglobulin, thyroid binding inhibitory immunoglobulins, thyroid scan, TSH, TSI, thyroxine, free T₄, triiodothyronine, free T₃, US thyroid, upper GI series, and UA.

▶ Refer to the Endocrine System table at the end of the book for tests by related body system.

Radiofrequency Ablation, Liver

SYNONYM/ACRONYM: RFA, RF ablation.

COMMON USE: To assist in treating tumors of the liver that are too small for surgery or have poor response to chemotherapy.

AREA OF APPLICATION: Liver.

CONTRAST: Done without contrast.

DESCRIPTION: One minimally invasive therapy to eliminate tumors in organs such as the liver is called radiofrequency ablation (RFA). This technique works by passing electrical current in the range of radiofrequency waves between the needle electrode and the grounding pads placed on the patient's skin. A special needle electrode is placed in the tumor under the guidance of an imaging method such as ultrasound (US), computed tomography (CT) scanning (with or without iodinated contrast), or magnetic resonance imaging (MRI). A radiofrequency current is then passed through the electrode to heat the tumor tissue near the needle tip and to ablate, or eliminate, it. The current creates heat around the electrode inside the tumor, and this heat spreads out to destroy the entire tumor but little of the surrounding normal liver tissue. The heat from radiofrequency energy

also closes up small blood vessels, thereby minimizing the risk of bleeding. Because healthy liver tissue withstands more heat than a tumor, RFA is able to destroy a tumor and a small rim of normal tissue about its edges without affecting most of the normal liver. The dead tumor cells are gradually replaced by scar tissue that shrinks over time. This approach is used in destroying liver tumors that may have failed to respond to chemotherapy or have recurred after initial surgery. If there are multiple tumor nodules, they may be treated in one or more sessions. In general, RFA causes only minimal discomfort and may be done as an outpatient procedure without general anesthesia. The procedure can be performed percutaneously, laproscopically, or by open surgery. RFA is most effective if the tumor is less than 4 cm in diameter; results are not as good when RFA is used

to treat larger tumors. Similar therapy is being used to treat tumors in the kidney, pancreas, bone, thyroid, breast, adrenal gland, and lung.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation (if CT is performed with or without contrast) far outweigh the risk of radiation exposure to the fetus.
-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).
Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.
-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma,

treatment with aminoglycosides and NSAIDs) because iodinated contrast is nephrotoxic.

-  Elderly and compromised patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
-  Patients with the presence of large or numerous tumors (studies show that RFA is most successful if fewer than 3 tumors are present and each lesion is not greater than 3 cm in size; ablation of tumors that occupy greater than 40% of the liver may not leave sufficient liver capacity to support normal function).
-  Patients with metastasis to the bile duct or surrounding hepatic vessel.
-  Patients with bile duct or major vessel invasion.
-  Patients with significant extrahepatic disease.
-  Patients with bleeding disorders who are receiving an arterial or venous puncture, because the site may not stop bleeding.

INDICATIONS

- Ablation of metastases to the liver
- Ablation of primary liver tumors, with hepatocellular carcinoma
- Therapy for multiple small liver tumors that are too spread out to remove surgically
- Therapy for recurrent liver tumors
- Therapy for tumors that are less than 2 in. in diameter
- Therapy for tumors that have failed to respond to chemotherapy
- Therapy for tumors that have recurred after initial surgery

POTENTIAL DIAGNOSIS

Normal findings in

- Decrease in tumor size
- Normal size, position, contour, and texture of the liver

Abnormal findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, rings, surgery clips) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Failure to follow dietary restrictions and other pretesting preparations before the procedure may cause the procedure to be canceled or repeated.

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing liver function.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's hepatobiliary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including barium examinations.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). Such products should be discontinued by medical direction for the appropriate number of days prior to a surgical procedure. Note the last time and dose of medication taken.
- ▶ Note that if iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**

Review the procedure with the patient. Address concerns about pain related to the procedure and explain that a sedative and/or analgesia will be administered to promote relaxation and reduce discomfort prior to the needle electrode insertion. Explain that any discomfort with the needle electrode will be minimized with local anesthetics and systemic analgesics. Inform the patient that the procedure is performed in the radiology department by an HCP, with support staff, and takes approximately 30 to 90 min.

Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, contrast medium, or emergency medications.

Sensitivity to social and cultural issues, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.

This procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Instruct the patient to avoid taking anticoagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

procedure and last for approximately 5 days.

Establishing an IV site and injecting contrast medium by catheter are invasive procedures. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; hematoma **related to blood leakage into the tissue following needle insertion**; or infection **that might occur if bacteria from the skin surface is introduced at the puncture site.**

Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

Ensure that the patient has complied with dietary, fluid, and medication restrictions and pretesting preparations.

Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

Have emergency equipment readily available.

Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug.

Instruct the patient to void and change into the gown, robe, and foot coverings provided.

Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

Record baseline vital signs and assess neurological status. Protocols may vary among facilities.

Establish an IV fluid line for the injection of saline, sedatives, contrast medium, or emergency medications.

Administer an anti-anxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.

INTRATEST:

Potential Complications:

Complications related to the ablation are rare but may include brief or long-lasting shoulder pain, inflammation of the gallbladder, damage to the bile ducts with resulting biliary obstruction, thermal damage to the bowel, thermal damage to surrounding tissue resulting in cellulitis, hemorrhage, or flu-like symptoms that appear 3 to 5 days after the

- ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.
- ▶ Place the patient in the supine position on an examination table. Cleanse the selected area, and cover with a sterile drape.
- ▶ A local anesthetic is injected at the site, and a needle electrode is inserted under ultrasound, CT, or MRI guidance.
- ▶ A radiofrequency current is passed through the needle electrode, and the tumor is ablated.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- ▶ The needle electrode is removed, and a pressure dressing is applied over the puncture site.
- ▶ Observe/assess the needle electrode insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and as ordered. Take temperature every 6 hr for 24 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Instruct the patient to immediately report bile leakage, inflammation, any pleuritic pain, persistent right shoulder pain, or abdominal pain.
- ▶ Observe/assess the needle electrode insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Instruct the patient to maintain bed rest for 4 to 6 hr after the procedure or as ordered.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to physical activity. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography abdomen, AST, biopsy liver, CT liver, MRI abdomen, and US liver and biliary system.
- ▶ Refer to the Hepatobiliary System table at the end of the book for related tests by body system.

Radiography, Bone

SYNONYM/ACRONYM: Arm x-rays, bone x-rays, leg x-rays, rib x-rays, spine x-rays.

COMMON USE: To assist in evaluating bone pain, trauma, and abnormalities related to disorders or events such as dislocation, fracture, abuse, and degenerative disease.

AREA OF APPLICATION: Skeleton.

CONTRAST: None.

DESCRIPTION: Skeletal x-rays are noninvasive studies used to evaluate extremity pain or discomfort due to trauma, bone and spine abnormalities, or fluid within a joint. Serial skeletal x-rays are used to evaluate growth pattern. Radiation emitted from the x-ray machine passes through the patient onto an image receptor. X-rays pass through air freely and are absorbed by the anatomical structures of the body in varying degrees based on density. Bones are very dense and therefore absorb or attenuate most of the x-rays passing into the body and appear white; organs and muscles are denser than air but not as dense as bone, so they appear in various shades of gray. Metals absorb x-rays and appear white and thus facilitate the search for foreign bodies in the patient.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Assist in detecting bone fracture, dislocation, deformity, and degeneration
- Evaluate for child or elder abuse
- Evaluate growth pattern
- Identify abnormalities of bones, joints, and surrounding tissues
- Monitor fracture healing process

POTENTIAL DIAGNOSIS

Normal findings in

- *Infants and children:* Thin plate of cartilage, known as growth plate or epiphyseal plate, between the shaft and both ends
- *Adolescents and adults:* By age 17, calcification of cartilage plate; no evidence of fracture, congenital abnormalities, tumors, or infection

Abnormal findings in

- Arthritis
- Bone degeneration
- Bone spurs
- Foreign bodies
- Fracture
- Genetic disturbance (achondroplasia, dysplasia, dyostosis)
- Hormonal disturbance
- Infection, including osteomyelitis
- Injury
- Joint dislocation or effusion
- Nutritional or metabolic disturbances

- Osteoporosis or osteopenia
- Soft tissue abnormalities
- Tumor or neoplastic disease (osteogenic sarcoma, Paget's disease, myeloma)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and can produce unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging**

Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should

wear badges to record their level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
 - ▶ **Patient Teaching:** Inform the patient this procedure can assist in examining bone structure.
 - ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, or sedatives.
 - ▶ Obtain a history of the patient's musculoskeletal system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
 - ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
 - ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
 - ▶ Review the procedure with the patient. Explain that numerous x-rays may be taken depending on the bones or joint affected. Address concerns about pain and explain that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in the radiology department by an HCP, with support staff, and takes approximately 10 to 30 min.
- Pediatric Considerations**
Preparation of children for a bone radiography depends on the age of the child. Encourage parents to be truthful about what the child may experience during the procedure and to use words that they know their child will understand. Toddlers and preschool-age children have very short attention spans, so the

best time to talk about the test is right before the procedure. The child should be assured that he or she will be allowed to bring a favorite comfort item into the examination room, and if appropriate, that a parent will be with the child during the procedure. Provide older children with information about the test and allow them to participate in as many decisions as possible (e.g., choice of clothes to wear to the appointment) in order to reduce anxiety and encourage cooperation. If the child will be asked to maintain a certain position for the test, encourage the child to practice the required position, provide a CD that demonstrates the procedure, and teach strategies to remain calm, such as deep breathing, humming, or counting to himself or herself.

- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the image is taken. Warn the patient that the extremity's position during the procedure may be uncomfortable, but ask the patient to hold very still during the procedure because movement will produce unclear images.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed all external metallic objects from the area to be examined prior to the procedure.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Place patient in a standing, sitting, or recumbent position in front of the image receptor.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken.
- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still throughout the procedure because movement produces unreliable results.

POST-TEST:

- ▶ Inform the patient that a report of the examination will be sent to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to the perceived loss of daily function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org) or for the Arthritis Foundation (www.arthritis.org).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Explain the importance of adhering to the therapy regimen. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

▶ Related tests include antibodies anti-cyclic citrullinated peptide, ANA, arthrogram, arthroscopy, biopsy bone, BMD, bone scan, calcium, CBC, CRP, collagen cross-linked telopeptides, CT spine, ESR, MRI

musculoskeletal, osteocalcin, phosphorus, synovial fluid analysis, RF, vitamin D, and WBC scan.

▶ Refer to the Musculoskeletal System table at the end of the book for related tests by body system.

Red Blood Cell Cholinesterase

SYNONYM/ACRONYM: Acetylcholinesterase (AChE), erythrocyte cholinesterase, true cholinesterase.

COMMON USE: To assess for pesticide toxicity and screen for cholinesterase deficiency, which may contribute to unrecoverable apnea after surgical induction with succinylcholine.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Spectrophotometry, kinetic)

Test	Conventional Units
RBC cholinesterase	5,300–10,000 international units/L

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Increased in

- Hemolytic anemias (e.g., sickle cell anemia, thalassemias, spherocytosis, and acquired hemolytic anemias) (*increased in hemolytic anemias as AChE is released from the hemolyzed RBCs*)

Decreased in

- Insecticide exposure (*organic phosphate insecticides inhibit AChE activity*)
- Late pregnancy (*related to anemia of pregnancy*)
- Paroxysmal nocturnal hemoglobinuria (*related to lack of RBC production by bone marrow*)
- Relapse of megaloblastic anemia (*related to underproduction of normal RBCs containing AChE*)

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Refraction

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess the visual acuity of the eyes in patients of all ages, to evaluate visual acuity as required by driver licensing laws, and to assist in evaluating the eyes prior to therapeutic interventions such as eyeglasses, contact lenses, low vision aids, cataract surgery, or LASIK surgery.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A

DESCRIPTION: This noninvasive procedure tests the visual acuity (VA) of the eyes and determines abnormalities or refractive errors that need correction. Refractions are performed using a combination of different pieces of equipment. Refractive error can be quickly and accurately measured using computerized automatic refractors or manually with a viewing system consisting of an entire set of trial lenses mounted on a circular wheel (phoropter). A projector may also be used to display test letters and characters from Snellen eye charts for use in assessing VA. If the VA is worse than 20/20, the pinhole test may be used to quickly assess the best corrected vision. Refractive errors of the peripheral cornea and lens can be reduced or eliminated by having the patient look through a pinhole at the vision test. Patients with cataracts or visual field defects will not show improved results using the pinhole test. The retinoscope is probably the most valuable instrument that can be used to objectively assess VA. It is also the only objective means of assessing refractive error in

pediatric patients and patients who are unable to cooperate with other techniques of assessing refractive error due to illiteracy, senility, or inability to speak the same language as the examiner. Visual defects identified through refraction, such as hyperopia (farsightedness), in which the point of focus lies behind the retina; myopia (nearsightedness), in which the point of focus lies in front of the retina; and astigmatism, in which the refraction is unequal in different curvatures of the eyeball, can be corrected by glasses, contact lenses, or refractive surgery.

This procedure is contraindicated for

-  Patients with narrow-angle glaucoma if pupil dilation is performed; dilation can initiate a severe and sight-threatening open-angle attack.
-  Patients with allergies to mydriatics if pupil dilation using mydriatics is performed.

INDICATIONS

- Determine if an optical defect is present and if light rays entering

the eye focus correctly on the retina

- Determine the refractive error prior to refractive surgery such as radial keratotomy (RK), photorefractive keratotomy (PRK), laser-assisted in situ keratomileusis (LASIK), intracorneal rings (Intacs), limbal relaxing incisions (LRI), implantable contact lens (phakic intraocular lens [IOL]), clear lens replacement
- Determine the type of corrective lenses (e.g., biconvex or plus lenses for hyperopia, biconcave or minus lenses for myopia, compensatory lenses for astigmatism) needed for refractive errors
- Diagnose refractive errors in vision

POTENTIAL DIAGNOSIS

Visual Acuity Scale

Foot	Meter	Decimal
20/200	6/60	0.1
20/160	6/48	0.13
20/120	6/36	0.17
20/100	6/30	0.2
20/80	6/24	0.25
20/60	6/18	0.33
20/50	6/15	0.4
20/40	6/12	0.5
20/30	6/9	0.67
20/25	6/7.5	0.8
20/20	6/6	1
20/16	6/4.8	1.25
20/12	6/3.6	1.67
20/10	6/3	2

VA can be expressed fractionally in feet, fractionally in meters, or as a decimal where perfect vision of 20/20 feet or 6/6 meters is equal to 1. Comparing the fraction in feet or meters to the decimal helps demonstrate that acuity less than 20/20, or less than 1.0, is "worse" vision, and acuity greater than 20/20, or greater than 1.0, is "better." A patient who cannot achieve best corrected VA of 20/200 or above (greater than 0.1) in his or her better eye is considered legally blind in the United States.

Uncorrected Visual Acuity	Foot	Meter	Decimal
Mild vision loss	20/30–20/70	6/9–6/21	0.67–0.29
Moderate vision loss	20/80–20/160	6/24–6/48	0.25–0.13
Severe vision loss	20/200–20/400	6/60–6/120	0.1–0.05
Profound vision loss	20/500–20/1,000	6/150–6/300	0.04–0.02

Normal findings in

- Normal visual acuity; 20/20 (with corrective lenses if appropriate).

Abnormal findings in

- Refractive errors such as anisometropia, astigmatism, hyperopia, myopia and presbyopia.

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Improper pupil dilation may prevent adequate examination for refractive error.
- Inability of the patient to cooperate and remain still during the procedure because of age, significant pain, or mental status may interfere with the test results.
- Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing visual acuity.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially mydriatics if dilation is to be performed.
- ▶ Obtain a history of the patient's known or suspected vision loss; changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- ▶ Obtain a history of symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate.

Instruct the patient regarding the importance of keeping the eyes open for the test.

- ▶ Review the procedure with the patient. Address concerns about pain and explain that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye. Inform the patient that a health-care provider (HCP) performs the test, in a quiet, darkened room, and that to evaluate both eyes, the test can take up 30 min (including time for the pupils to dilate before the test is actually performed).
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.
- ▶ Instruct the patient to withhold eye medications (particularly miotic eye drops which may constrict the pupil preventing a clear view of the fundus and mydriatic eyedrops in order to avoid instigation of an acute open angle attack in patients with narrow angle glaucoma) for at least 1 day prior to the test.
- ▶ Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hours) after the test and has made arrangements to have someone else be responsible for transportation after the test.

INTRATEST:

Potential Complications:

- ▶ Dilation can initiate a severe and sight-threatening open-angle attack in patients with narrow-angle glaucoma.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with medication restrictions and

pretesting preparations; assure that eye medications, especially mydriatics, have been restricted for at least 1 day prior to the procedure.

- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- ▶ If dilation is to be performed, administer the ordered mydriatic to each eye and repeat in 5 to 15 min. Drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (gray, semitransparent area of the eyeball where the cornea and sclera meet). The dropper bottle should not touch the eyelashes.
- ▶ Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar. The examiner will sit about 2 ft away at eye level with the patient. The retinoscope light is held in front of the eyes and directed through the pupil. Each eye is also examined for the characteristics of the red reflex, the reflection of the light from the retinoscope, which normally moves in the same direction as the light.
- ▶ Request that the patient look straight ahead while the eyes are examined with the instrument and while different lenses are tried to provide the best corrective lenses to be prescribed. When optimal VA is obtained with the trial lenses in each eye, a prescription for corrective lenses is written.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available

to the requesting HCP, who will discuss the results with the patient.

- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to vision loss, anticipated loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for a general patient education Web site on the topic of eye care (e.g., www.allaboutvision.com).
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include color perception test, intraocular muscle function, intraocular pressure, Schirmer tear test, and slit-lamp biomicroscopy.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Renin

SYNONYM/ACRONYM: Plasma renin activity (PRA), angiotensinogenase.

COMMON USE: To assist in evaluating for a possible cause of hypertension.

SPECIMEN: Plasma (3 mL) collected in a lavender-top (EDTA) or pink-top (K₂EDTA) tube.

NORMAL FINDINGS: (Method: Radioimmunoassay)

Age and Position	Conventional Units	SI Units (Conventional Units × 1)
Newborn–12 mo Supine, normal sodium diet	2–35 ng/mL/hr	2–35 mcg/L/hr
1–3 yr	1.7–11.2 ng/mL/hr	1.7–11.2 mcg/L/hr
4–5 yr	1–6.5 ng/mL/hr	1.0–6.5 mcg/L/hr
6–10 yr	0.5–5.9 ng/mL/hr	0.5–5.9 mcg/L/hr
11–15 yr	0.5–3.3 ng/mL/hr	0.5–3.3 mcg/L/hr
Adult Upright, normal sodium diet	0.2–2.3 ng/mL/hr	0.2–2.3 mcg/L/hr
Adult–older adult	1.3–4 ng/mL/hr	1.3–4 mcg/L/hr

Values vary according to the laboratory performing the test, as well as the patient's age, gender, dietary pattern, state of hydration, posture, and physical activity.

DESCRIPTION: Renin is an enzymatic peptide hormone secreted by the granular cells of the juxtaglomerular apparatus in the kidney in response to sodium depletion and hypovolemia. Renin activates the renin-angiotensin system through the conversion of angiotensinogen to angiotensin I. Angiotensin I is converted to the biologically active angiotensin II by angiotensin-converting enzyme primarily within the capillaries of the lungs. Angiotensin II is a powerful vasoconstrictor that ultimately maintains the appropriate perfusion pressure in the kidneys. Angiotensin II stimulates

aldosterone production in the adrenal cortex, secretion of antidiuretic hormone from the pituitary, and stimulates the thirst reflex from the hypothalamus. The net effect is regulation of blood pressure by regulating arterial vasoconstriction and the movement of extracellular fluids such as plasma, lymphatic fluid, and interstitial fluid. Excessive amounts of angiotensin II cause renal hypertension. The random collection of specimens without prior dietary preparations does not provide clinically significant information. Values should also be evaluated along with

simultaneously collected aldosterone levels (see monographs titled “Aldosterone” and “Angiotensin-Converting Enzyme”).

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the identification of primary hyperaldosteronism resulting from aldosterone-secreting adrenal adenoma
- Assist in monitoring patients on mineralocorticoid therapy
- Assist in the screening of the origin of essential, renal, or renovascular hypertension

POTENTIAL DIAGNOSIS

Increased in

- Addison's disease (*related to hyponatremia, which stimulates production of renin*)
- Bartter's syndrome (*related to hereditary defect in loop of Henle that affects sodium resorption; hyponatremia stimulates renin production*)
- Cirrhosis (*related to fluid buildup, which dilutes sodium concentration; hyponatremia is a strong stimulus for production of renin*)
- Congestive heart failure (*related to fluid buildup, which dilutes sodium concentration; hyponatremia is a strong stimulus for production of renin*)
- Gastrointestinal disorders with electrolyte loss (*related to hyponatremia, which stimulates production of renin*)
- Hepatitis (*related to fluid buildup, which dilutes sodium concentration; hyponatremia is a strong stimulus for production of renin*)
- Hypokalemia (*related to decreased potassium levels, which stimulate renin production*)

- Malignant hypertension (*related to secondary hyperaldosteronism that constricts the blood vessels and results in hypertension*)
- Nephritis (*the kidneys can produce renin in response to inflammation or disease*)
- Nephropathies with sodium or potassium wasting (*related to hyponatremia, which stimulates production of renin*)
- Pheochromocytoma (*related to renin production in response to hypertension*)
- Pregnancy (*related to retention of fluid and hyponatremia that stimulates renin production; normal pregnancy is associated with changes in the balance between renin and angiotensin*)
- Renin-producing renal tumors
- Renovascular hypertension (*related to decreased renal blood flow, which stimulates release of renin*)

Decreased in

- Cushing's syndrome (*related to excessive production of glucocorticoids, which increase sodium levels and decrease potassium levels, inhibiting renin production*)
- Primary hyperaldosteronism (*related to aldosterone-secreting adrenal tumor; aldosterone inhibits renin production*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase renin levels include albuterol, amiloride, azosemide, benazepril, bendroflumethiazide, captopril, chlorthalidone, cilazapril, cromakalim, desmopressin, diazoxide, dihydralazine, doxazosin, enalapril, endralazine, felodipine, fenoldopam, fosinopril, furosemide, hydralazine, hydrochlorothiazide, laxatives, lisinopril, lithium,

methyclothiazide, metolazone, muzolimine, nifedipine, nifedipine, opiates, oral contraceptives, perindopril, ramipril, spironolactone, triamterene, and xipamide.

- Drugs and substances that may decrease renin levels include acetylsalicylic acid, angiotensin, angiotensin II, atenolol, bopindolol, bucindolol, carbenoxolone, carvedilol, clonidine, cyclosporin A, dexfenfluramine, glycyrrhiza, ibuprofen, indomethacin, levodopa, metoprolol, naproxen, nifedipine, NSAIDs, oral contraceptives, oxprenolol, propranolol, sulindax, and vasopressin.
- Upright body posture, stress, and strenuous exercise can increase renin levels.
- Recent radioactive scans or radiation can interfere with test results when radioimmunoassay is the test method.
- Diet can significantly affect results (e.g., low-sodium diets stimulate the release of renin).
- Hyperkalemia, acute increase in blood pressure, and increased blood volume may suppress renin secretion.
- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating for high blood pressure.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.

- ▶ Obtain a history of the patient's endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient or family member that the position required (supine or upright) must be maintained for 2 hr before specimen collection. Inform the patient that multiple specimens may be required. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ The patient should be on a normal sodium diet (1 to 2 g sodium per day) for 2 to 4 wk before the test. Protocols may vary among facilities.
- ▶ By medical direction, the patient should avoid diuretics, antihypertensive drugs, herbals, cyclic progestogens, and estrogens for 2 to 4 wk before the test.
- ▶ Prepare an ice slurry in a cup or plastic bag to have ready for immediate transport of the specimen to the laboratory.

INTRATEST:

Potential Complications: N/A

- ▶ Ensure that the patient has complied with diet and medication restrictions and pretesting dietary preparations; ensure that specific medications have been restricted for at least 2 to 4 wk prior to the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A.

Positively identify the patient, and label the appropriate tubes with the corresponding patient demographics, date, and time of collection. Specify patient position (upright or supine) and exact source of specimen (peripheral vs. arterial). Perform a venipuncture after the patient has been in the upright (sitting or standing) position for 2 hr. If a supine specimen is requested on an inpatient, the specimen should be collected early in the morning before the patient rises.

- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ The sample should be placed in an ice slurry immediately after collection. Information on the specimen label should be protected from water in the ice slurry by first placing the specimen in a protective plastic bag. Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ **Nutritional Considerations:** Instruct the patient to notify the requesting HCP of any signs and symptoms of dehydration or fluid overload related to abnormal renin levels or compromised sodium regulatory mechanisms. Fluid loss or dehydration is signaled by the thirst response. Decreased skin turgor, dry mouth, and multiple longitudinal furrows in the tongue are symptoms of dehydration. Fluid overload may be signaled by a loss of appetite and nausea. Excessive fluid also causes pitting edema: When firm pressure is placed on the skin over a bone (e.g., the ankle), the indentation will remain after 5 sec.
- ▶ **Nutritional Considerations:** Educate patients of the importance of proper water balance. In buildings with hard water, untreated tap water contains minerals such as calcium, magnesium, and iron. Water-softening systems replace these minerals with sodium,

and therefore patients on a low-sodium diet should avoid drinking treated tap water and drink bottled water instead.

- ▶ **Nutritional Considerations:** Renin levels affect the regulation of fluid balance and electrolytes. If appropriate, educate patients with low sodium levels that the major source of dietary sodium is found in table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through the consumption of processed foods. Patients on low-sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels. The requesting HCP or nutritionist should be consulted before the patient on a low-sodium diet begins using salt substitutes. Potassium is present in all plant and animal cells, making dietary replacement fairly simple to achieve.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, ALT, aldosterone, ACE, AST, ANP, BNP, bilirubin, biopsy kidney, BUN, calcium, chloride, cortisol, creatinine, DHEAS, fecal fat, GGT, glucose, GTT, magnesium, metanephrines, potassium, protein total and fractions, renogram, sodium, UA, and VMA.
- ▶ Refer to the Endocrine and Genitourinary systems tables at the end of the book for related tests by body system.

Renogram

SYNONYM/ACRONYM: Radioactive renogram, renocystography, renocystogram, renal scintigraphy.

COMMON USE: To assist in diagnosing renal disorders such as embolism, obstruction, infection, inflammation, trauma, stones, and bleeding.

AREA OF APPLICATION: Kidneys.

CONTRAST: IV radioactive material.

DESCRIPTION: A renogram is a nuclear medicine study performed to assist in diagnosing renal disorders, such as abnormal blood flow, collecting-system defects, and excretion dysfunction. Because renography uses noniodinated contrast medium, it is safe to use in patients who have iodine allergies or compromised renal function.

After IV administration of the radioisotope, information about the structures of the kidneys is obtained. The radioactive material is detected by a gamma camera, which can detect the gamma rays emitted by the radionuclide in the kidney. Renography simultaneously tracks the rate at which the radionuclide flows into (*vascular phase*), through (*tubular phase*), and out of (*excretory phase*) the kidneys. The times are plotted on a graph and compared to normal parameters of organ function. Differential estimates of left and right kidney contributions to glomerular filtration rate and effective renal plasma flow can be calculated. With the use of diuretic stimulation during the excretory phase, it is possible to differentiate between anatomic obstruction and nonobstructive residual

dilation from previous hydronephrosis. All information obtained is stored in a computer to be used for further interpretation and computations. Renal function can be monitored by serially repeating this test and comparing results.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.

INDICATIONS

- Aid in the diagnosis of renal artery embolism or renal infarction causing obstruction
- Aid in the diagnosis of renal artery stenosis resulting from renal dysplasia or atherosclerosis and causing arterial hypertension and reduced glomerular filtration rate
- Aid in the diagnosis of renal vein thrombosis resulting from dehydration in infants or obstruction of blood flow in the presence of renal tumors in adults
- Detect renal infectious or inflammatory diseases, such as acute or

chronic pyelonephritis, renal abscess, or nephritis

- Determine the presence and effects of renal trauma, such as arterial injury, renal contusion, hematoma, rupture, arteriovenous fistula, or urinary extravasation
- Determine the presence, location, and cause of obstructive uropathy, such as calculi, neoplasm, congenital disorders, scarring, or inflammation
- Evaluate acute and chronic renal failure
- Evaluate chronic urinary tract infections, especially in children
- Evaluate kidney transplant for acute or chronic rejection
- Evaluate obstruction caused by stones or tumor

POTENTIAL DIAGNOSIS

Normal findings in

- Normal shape, size, position, symmetry, vasculature, perfusion, and function of the kidneys
- Radionuclide material circulates bilaterally, symmetrically, and without interruption through the renal parenchyma, ureters, and urinary bladder, with 50% of the radionuclide excreted within the first 10 min

Abnormal findings in

- Acute tubular necrosis
- Congenital anomalies (e.g., absence of a kidney)
- Decreased renal function
- Diminished blood supply
- Infection or inflammation (pyelonephritis, glomerulonephritis)
- Masses
- Obstructive uropathy
- Renal failure, infarction, cyst, or abscess
- Renal vascular disease, including renal artery stenosis or renal vein thrombosis
- Trauma

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.
- Serum creatinine levels greater than or equal to 3 mg/dL (depending on the radionuclide used), which can decrease renal perfusion.
- Other nuclear medicine studies done within the previous 24 to 48 hr.
- Medications such as antihypertensives, angiotensin-converting enzyme (ACE) inhibitors, and β -blockers taken within 24 hr of the test.
- Dehydration, which can accentuate abnormalities, or overhydration, which can mask abnormalities.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization.

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray or radionuclide procedures. Personnel working in the

examination area should wear badges to record their level of radiation exposure.

- Inaccurate timing of imaging after the radionuclide injection can affect the results.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the renal system.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, sedatives, or radionuclides.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, and there may be moments of discomfort. Reassure the patient that radioactive material poses minimal radioactive hazard because of its short half-life and rarely produces side effects. Inform the patient that the procedure is performed in a nuclear medicine department by an HCP and usually takes approximately 60 to 90 min, and that delayed images are needed 2 to 24 hr later. The patient may leave the department and return later to undergo delayed imaging.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, radionuclides, medications used in the procedure, or emergency medications.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Inform the patient that he or she will be asked to drink several glasses of fluid before the study for hydration, unless the patient has a restricted fluid intake for other reasons.
- ▶ Note that there are no food or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Although it is rare, there is the possibility of allergic reaction to the radionuclide. Have emergency equipment and medications readily available. If the patient has a history of allergic reactions to any substance or drug, administer ordered prophylactic steroids or antihistamines before the procedure. Establishing an IV site and injecting radionuclides is an invasive procedure. Complications are rare but do include bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners;** hematoma **related to blood leakage into the tissue following needle insertion;** infection **that might occur if bacteria from the skin surface is introduced at the puncture site;** or nerve injury **that might occur if the needle strikes a nerve.**

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed external metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.

- ▶ Have emergency equipment readily available.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, anesthetics, sedatives, radionuclides, or emergency medications.
- ▶ Administer sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place the patient in a supine position on a flat table with foam wedges to help maintain position and immobilization.
- ▶ The radionuclide is administered IV, and the kidney area is scanned immediately with images taken every minute for 30 min.
- ▶ During the flow and static imaging, the diuretic furosemide (Lasix) or ACE inhibitor (captopril) can be administered IV and images obtained.
- ▶ Urine and blood laboratory studies are done after the renogram to correlate findings before diagnosis.
- ▶ If a study for vesicoureteral reflux is done, the patient is asked to void, and a catheter is inserted into the bladder. The radionuclide is instilled into the bladder, and multiple images are obtained during bladder filling. The patient is then requested to void, with the catheter in place or after catheter removal, depending on department policy. Imaging is continued during and after voiding. Reflux is determined by calculating the urine volume and counts obtained by imaging.
- ▶ Gloves should be worn during the radionuclide administration and while handling the patient's urine.
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Unless contraindicated, advise patient to drink increased amounts of fluids for

24 hr to eliminate the radionuclide from the body. Inform the patient that radionuclide is eliminated from the body within 6 to 24 hr.

- ▶ Instruct the patient to immediately flush the toilet and to meticulously wash hands with soap and water after each voiding for 24 hr after the procedure.
- ▶ Instruct all caregivers to wear gloves when discarding urine for 24 hr after the procedure. Wash gloved hands with soap and water before removing gloves. Then wash ungloved hands after the gloves are removed.
- ▶ Observe/assess the needle/catheter site for bleeding, hematoma formation, and inflammation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical importance of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography renal, antibodies anti-glomerular basement membrane, biopsy kidney, bladder cancer markers, BUN, calculus kidney stone panel, C4, CT abdomen, CT pelvis, CT renal, creatinine, creatinine clearance, cystoscopy, IVP, KUB studies, MRA, MRI abdomen, retrograde ureteropyelography, strep group A, US abdomen, US kidney, and UA.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Reticulocyte Count

SYNONYM/ACRONYM: Retic count.

COMMON USE: To assess reticulocyte count in relation to bone marrow activity toward diagnosing anemias such as pernicious iron deficiency, and hemolytic; to monitor response of therapeutic interventions.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method:Automated analyzer or microscopic examination of specially stained peripheral blood smear)

Age	Reticulocyte Count %
Newborn	2%–4.8%
7–30 days	0.4%–2.8%
31–60 days	0.9%–3.8%
3 mo–18 yr	0.8%–2.1%
Adult–older adult	0.8%–2.5%
Reticulocyte Count (absolute number)	
Birth–older adult	0.02–0.10 (10^6 cells/microL)
Immature Reticulocyte Fraction %	
Birth	2.5%–6.5%
Newborn–older adult	2.5%–17%
Reticulocyte Hemoglobin	
Birth	22–32 pg/cell
Newborn–18 yr	23–34 pg/cell
Adult–older adult	30–35 pg/cell

DESCRIPTION: Normally, as it matures, the red blood cell (RBC) loses its nucleus. The remaining ribonucleic acid (RNA) produces a characteristic color when special stains are used, making these cells easy to identify and enumerate. Some automated cell counters have the ability to provide a reticulocyte panel, which includes the enumeration of circulating reticulocytes as an absolute count and as a percentage of total RBCs; the immature reticulocyte fraction

(IRF), which reflects the number of reticulocytes released into the circulation within the past 24 to 48 hours; and the reticulocyte hemoglobin (Ret-He) content, which reflects the amount of iron incorporated into the maturing RBCs. The presence of reticulocytes is an indication of the level of erythropoietic activity in the bone marrow. The information provided by the reticulocyte panel is useful in the evaluation of anemias, bone marrow response to

therapy, degree of bone marrow engraftment following transplant, and the effectiveness of altitude training in high-performance athletes. In abnormal conditions, reticulocytes are prematurely released into circulation. (See monographs titled “Complete Blood Count, RBC Count” and “Complete Blood Count, RBC Morphology and Inclusions.”)

This procedure is contraindicated for: N/A

INDICATIONS

- Evaluate erythropoietic activity
- Monitor response to therapy for anemias

POTENTIAL DIAGNOSIS

The reticulocyte production index (RPI) is a good estimate of RBC production. The calculation corrects the count for anemia and for the premature release of reticulocytes into the peripheral blood during periods of hemolysis or significant bleeding. The RPI also takes into consideration the maturation time of large polychromatophilic cells or nucleated RBCs seen on the peripheral smear:

$$\text{RPI} = \% \text{ reticulocytes} \times \left[\frac{\text{patient hematocrit (Hct)}}{\text{normal Hct}} \right] \times (1 / \text{maturation time})$$

As the formula shows, the RPI is inversely proportional to Hct, as follows:

Hematocrit (%)	Maturation Time (days)
45	1
35	1.5
25	2
15	2.5

Increased in

Conditions that result in excessive RBC loss or destruction stimulate a

compensatory bone marrow response by increasing production of RBCs.

- Blood loss
- Hemolytic anemias
- Iron-deficiency anemia
- Megaloblastic anemia

Decreased in

- Alcoholism (*decreased production related to nutritional deficit*)
- Anemia of chronic disease
- Aplastic anemia (*related to overall lack of RBC*)
- Bone marrow replacement (*new marrow fails to produce RBCs until it engrafts*)
- Endocrine disease (*hypometabolism related to hypothyroidism is reflected by decreased bone marrow activity*)
- RBC aplasia (*related to overall lack of RBCs*)
- Renal disease (*diseased kidneys cannot produce erythropoietin, which stimulates the bone marrow to produce RBCs*)
- Sideroblastic anemia (*RBCs are produced but are abnormal in that they cannot incorporate iron into hemoglobin, resulting in anemia*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase reticulocyte counts include acetanilid, acetylsalicylic acid, amyl nitrate, antimalarials, antipyretics, antipyrine, arsenicals, corticotropin, dimercaprol, etretinate, furaltadone, furazolidone, levodopa, methyl dopa, nitrofurans, penicillin, procainamide, and sulfones.
- Drugs that may decrease reticulocyte counts include azathioprine, dactinomycin, hydroxyurea, methotrexate, and zidovudine.
- Reticulocyte count may be falsely increased by the presence of RBC inclusions (Howell-Jolly bodies, Heinz bodies, and Pappenheimer bodies) that stain with methylene blue.

- Reticulocyte count may be falsely decreased as a result of the dilutional effect after a recent blood transfusion.
- Specimens that are clotted or hemolyzed should be rejected for analysis.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in assessing for anemia.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the

patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, complement, CBC, CBC hematocrit, CBC hemoglobin, CBC RBC count, CBC RBC indices, CBC RBC morphology, Coomb's antiglobulin direct and indirect, erythropoietin, iron/TIBC, ferritin, folate, G6PD, Ham's test, Hgb electrophoresis, lead, osmotic fragility, PK, sickle cell screen, and vitamin B₁₂.
- ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Retrograde Ureteropyelography

SYNONYM/ACRONYM: Retrograde.

COMMON USE: To assess the urinary tract for trauma, obstruction, stones, infection, and abscess that can interfere with function.

AREA OF APPLICATION: Renal calyces, ureter.

CONTRAST: Radiopaque iodine-based contrast medium.

DESCRIPTION: Retrograde ureteropyelography uses a contrast medium introduced through a ureteral catheter during cystography and radiographic visualization to view the renal collecting system (calyces, renal pelvis, and urethra). During a cystoscopic examination, a catheter is advanced through the ureters and into the kidney and contrast medium is injected through the catheter into the kidney. This procedure is primarily used in patients who are known to be hypersensitive to IV injected iodine-based contrast medium and when excretory ureterography does not adequately reveal the renal collecting system. The incidence of allergic reaction to the contrast medium is reduced because there is less systemic absorption of the contrast medium when injected into the kidney than when injected IV. Retrograde ureteropyelography sometimes provides more information about the anatomy of the different parts of the collecting system than can be obtained by excretory ureteropyelography. Computed tomography (CT) and ultrasound studies are replacing retrograde pyelography because they are less invasive and the quality of the technology has significantly improved.

This procedure is contraindicated for

- ◆ Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
- ◆ Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of non-ionic contrast or an alternative non-contrast imaging study, if available, may be considered for patients who have severe asthma or who have experienced moderate to severe reactions to ionic contrast medium.

- ◆ Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) because iodinated contrast is nephrotoxic.
- ◆ Elderly and compromised patients who are chronically dehydrated before the test, because of their risk of contrast-induced renal failure.
- ◆ Patients with bleeding disorders because the puncture site may not stop bleeding.

INDICATIONS

- Evaluate the effects of urinary system trauma
- Evaluate known or suspected ureteral obstruction
- Evaluate placement of a ureteral stent or catheter
- Evaluate the presence of calculi in the kidneys, ureters, or bladder
- Evaluate the renal collecting system when excretory urography is unsuccessful
- Evaluate space-occupying lesions or congenital anomalies of the urinary system
- Evaluate the structure and integrity of the renal collecting system

POTENTIAL DIAGNOSIS

Normal findings in

- Normal outline and opacification of renal pelvis and calyces
- Normal size and uniform filling of the ureters
- Symmetrical and bilateral outline of structures

Abnormal findings in

- Congenital renal or urinary tract abnormalities
- Hydronephrosis
- Neoplasms
- Obstruction as a result of tumor, blood clot, stricture, or calculi

- Obstruction of ureteropelvic junction
- Perinephric abscess
- Perinephric inflammation or suppuration
- Polycystic kidney disease
- Prostatic enlargement
- Tumor of the kidneys or the collecting system

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Gas or feces in the gastrointestinal tract resulting from inadequate cleansing or failure to restrict food intake before the study.
- Retained barium from a previous radiological procedure.
- Metallic objects (e.g., jewelry, body rings) within the examination field, which may inhibit organ visualization and cause unclear images.
- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Consultation with a health-care provider (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating.

Pediatric & Geriatric Imaging

Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a

protective lead apron, stand behind a shield or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

- Failure to follow dietary restrictions and other pretesting preparations may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing the urinary tract.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's genitourinary system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results, including examinations using barium.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function,

and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin.**

- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain may be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in a special department, usually in a radiology or vascular suite, by an HCP, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Inform the patient that he or she may receive a laxative the night before the test and an enema or a cathartic the morning of the test, as ordered.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications. Explain that the contrast medium will be injected, by catheter, at a separate site from the IV line.
- ▶ Inform the patient that if a local anesthetic is used, the patient may feel (1) some pressure in the kidney area as the catheter is introduced and contrast medium injected and (2) the urgency to void.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area to be examined prior to the procedure.
- ▶ Instruct the patient to fast and restrict fluids for 8 hr prior to the procedure. Instruct the patient to avoid taking anti-coagulant medication or to reduce dosage as ordered prior to the procedure. Protocols may vary among facilities.
- ▶ This procedure may be terminated if chest pain, severe cardiac arrhythmias, or signs of a cerebrovascular accident occur.

Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.

INTRATEST:

Potential Complications:

Establishing an IV site and injecting contrast medium by catheter are invasive procedures. Complications are rare but do include risk for allergic reaction **related to contrast reaction**; bleeding from the puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; hematoma **related to blood leakage into the tissue following needle insertion**; infection **that might occur if bacteria from the skin surface is introduced at the puncture site**; UTI **related to insertion of cystoscope or catheter**; hematuria **related to insertion of cystoscope**; and sepsis **related to bacterial contamination from infected urine**.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with dietary, fluid, and medication restrictions for 8 hr prior to the procedure.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to void prior to the procedure and to change into the gown, robe, and foot coverings provided.
- ▶ Instruct the patient to cooperate fully and to follow directions.

Instruct the patient to remain still throughout the procedure because movement produces unreliable results.

- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Administer an antianxiety agent, as ordered, if the patient has claustrophobia. Administer a sedative to a child or to an uncooperative adult, as ordered.
- ▶ Place electrocardiographic electrodes on the patient for cardiac monitoring. Establish baseline rhythm; determine if the patient has ventricular arrhythmias.
- ▶ Place patient supine on the table in the lithotomy position.
- ▶ A kidney, ureter, and bladder (KUB) or plain image is taken to ensure that no barium or stool will obscure visualization of the urinary system. The patient may be asked to hold his or her breath to facilitate visualization.
- ▶ The patient is given a local anesthetic, and a cystoscopic examination is performed and the bladder is inspected.
- ▶ A catheter is inserted, and the renal pelvis is emptied by gravity. Contrast medium is introduced into the catheter. Inform the patient that the contrast medium may cause a temporary flushing of the face, a feeling of warmth, or nausea.
- ▶ X-ray images are made and the results processed. Inform the patient that additional images may be necessary to visualize the area in question.
- ▶ Additional contrast medium is injected through the catheter to outline the ureters as the catheter is withdrawn.
- ▶ The catheter may be kept in place and attached to a gravity drainage unit until urinary flow has returned or is corrected.
- ▶ Additional x-ray images are taken 10 to 15 min after the catheter is removed to evaluate retention of the contrast medium, indicating urinary stasis.

- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP. Renal function should be assessed before metformin is resumed.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Monitor for signs of sepsis and severe pain in the kidney area.

- ▶ Maintain the patient on adequate hydration after the procedure. Encourage the patient to drink lots of fluids to prevent stasis and to prevent the buildup of bacteria.
- ▶ Recognize anxiety related to test results, and be supportive of perceived loss of independent function. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include angiography renal, BUN, calculus kidney stone panel, CT abdomen, creatinine, cystoscopy, IVP, KUB, MRI abdomen, PT/INR, PSA, renogram, US kidney, UA, and voiding cystourethrography.
- ▶ Refer to the Genitourinary System table at the end of the book for related tests by body system.

Rheumatoid Factor

SYNONYM/ACRONYM: RF, RA.

COMMON USE: To primarily assist in diagnosing rheumatoid arthritis.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube.

NORMAL FINDINGS: (Method: Immunoturbidimetric) Less than 14 international units/mL. Elevated values may be detected in healthy adults 60 yr and older.

DESCRIPTION: Rheumatoid arthritis (RA) is a chronic, systemic autoimmune disease that damages the synovium or membrane surrounding the joints. Collagen, the main fibrous protein in tendons, bone, and other types of connective tissue, is gradually destroyed, narrowing the joint space. As the disease progresses, a pannus or growth of thickened synovial tissue forms and permeates the bone and cartilage, leading to permanent damage and joint deformity. Inflammation caused by autoimmune responses can affect other organs and body systems. The American Academy of Rheumatology's current criteria focuses on earlier diagnosis of newly presenting patients who have at least one swollen joint unrelated to another condition. The criteria includes four determinants: joint involvement (number and size of joints involved), serological test results (rheumatoid factor [RF] and/or anticitrullinated protein antibody [ACPA]), indications of acute inflammation (C-reactive protein [CRP] and/or erythrocyte sedimentation rate [ESR]), and duration of symptoms. A score of 6 or greater defines

the presence of RA. Patients with longstanding RA, whose condition is inactive, or whose prior history would have satisfied the previous classification criteria by having four of seven findings—morning stiffness, arthritis of three or more joint areas, arthritis of hand joints, symmetric arthritis, rheumatoid nodules, abnormal amounts of rheumatoid factor, and radiographic changes—should remain classified as having RA. The study of RA is complex, and it is believed that multiple genes may be involved in the manifestation of RA. Individuals with RA harbor a macroglobulin-type antibody called *rheumatoid factor* in their blood. Patients with other diseases (e.g., systemic lupus erythematosus [SLE] and occasionally tuberculosis, chronic hepatitis, infectious mononucleosis, and subacute bacterial endocarditis) may also test positive for RF. RF antibodies are usually immunoglobulin (Ig) M but may also be IgG or IgA. Women are two to three times more likely to develop RA than men. While RA is most likely to affect people aged 35 to 50, it can affect all ages.

This procedure is contraindicated for: N/A

INDICATIONS

Assist in the diagnosis of rheumatoid arthritis, especially when clinical diagnosis is difficult

POTENTIAL DIAGNOSIS

Increased in

Pathophysiology is unclear, but RF is present in numerous conditions, including rheumatoid arthritis.

- Chronic hepatitis
- Chronic viral infections
- Cirrhosis
- Dermatomyositis
- Infectious mononucleosis
- Leishmaniasis
- Leprosy
- Malaria
- Rheumatoid arthritis

- Sarcoidosis
- Scleroderma
- Sjögren's syndrome
- SLE
- Syphilis
- Tuberculosis
- Waldenström's macroglobulinemia

Decreased in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Older healthy patients may have higher values.
- Recent blood transfusion, multiple vaccinations or transfusions, or an inadequately activated complement may affect results.
- Serum with cryoglobulin or high lipid levels may cause a false-positive test and may require that the test be repeated after a fat-restriction diet.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Self-care <i>(Related to immune system dysfunction)</i>	Joint stiffness; joint swelling; joint stiffness; joint pain; self-reports of difficulty in completing activities of daily living (ADLs); limited range of motion	Assess range of motion; administer prescribed anti-inflammatory drugs; teach exercises that will increase joint mobility and increase ability to participate in ADLs; teach the patient to take analgesics prior to activity to decrease pain and facilitate self-care
Mobility <i>(Related to deformed joints secondary to immune system dysfunction; fatigue; pain)</i>	Unsteady gait; lack of coordination; difficult purposeful movement; inadequate range of motion	Assess gait; assess muscle strength; assess weakness and coordination; assess physical endurance and level of fatigue; assess ability to perform independent ADLs; assess ability for safe independent movement; identify need for assistive device; encourage safe self-care; administer prescribed steroids

Problem	Signs & Symptoms	Interventions
Body image (<i>Related to deformed joints secondary to immune system dysfunction</i>)	Negative self remarks; expressions of feelings or concerns over visual physical changes; fear of rejection by others due to appearance	Assess feelings related to body image changes (refusal to discuss changes, participate in care, withdraw from social situations); encourage participation in support groups; emphasize strengths; determine the patient's expectations regarding appearance; identify the influence of the patient's culture, religion, race, and gender on body image perceptions; monitor verbalization of self-criticism
Fatigue (<i>Related to chronic illness; discomfort; immobility; psychological stress; pain</i>)	Disturbed sleep pattern; chronic pain; verbal report of fatigue	Suggest bedtime routine that will promote rest (warm bath, warm milk); pace activities balancing them with rest periods; assess the level of psychological stress and suggest assistive coping strategies; facilitate use of assistive devices

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing arthritic disorders.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and musculoskeletal systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that

specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results, and be supportive of impaired activity related to anticipated chronic pain resulting from joint inflammation, impairment in mobility, musculoskeletal deformity, and loss of independence. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding access to counseling services, as appropriate. Provide contact information, if desired, for the American College of Rheumatology (www.rheumatology.org) or for the Arthritis Foundation (www.arthritis.org).
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Anemia is a common complication of RA. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Advise the patient, as appropriate, that additional studies may be undertaken to determine treatment regimen or to determine the possible causes of symptoms if the test is negative for RA.
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that taking anti-inflammatory medication prior to activity may improve mobility
- ▶ States understanding of the risks and benefits of steroid use

Skills

- ▶ Demonstrates positive coping strategies and seeks support as appropriate
- ▶ Demonstrates the proficient use of assistive devices to support mobility and decrease fatigue

Attitude

- ▶ Complies with the request to attend a rheumatoid arthritis support group
- ▶ Complies with the request to minimize exposure to sick individuals when immunocompromised

RELATED MONOGRAPHS:

- ▶ Related laboratory tests include antibodies anticyclic citrullinated peptide, ANA, arthrogram, arthroscopy, biopsy bone, BMD, bone scan, calcium, collagen cross-linked telopeptides, CBC, CT spine, CRP, ESR, MRI musculoskeletal, osteocalcin, phosphorus, radiography bone, synovial fluid analysis, uric acid, vitamin D, and WBC scan.
- ▶ Refer to the Immune and Musculoskeletal systems tables at the end of the book for related tests by body system.

Rubella Antibodies, IgG and IgM

SYNONYM/ACRONYM: German measles serology.

COMMON USE: To assess for antibodies related to rubella immunity or for presence of rubella infection.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Chemiluminescent immunoassay)

	IgM	Interpretation	IgG	Interpretation
Negative	0.9 index or less	No significant level of detectable antibody	Less than 8 U/mL	No significant level of detectable antibody; indicative of nonimmunity
Indeterminate	0.91–1.09 index	Equivocal results; retest in 10–14 d	8–12 U/mL	Equivocal results; retest in 10–14 d
Positive	1.1 index or greater	Antibody detected; indicative of recent immunization, current or recent infection	Greater than 12 U/mL	Antibody detected; indicative of immunization, current or past infection

DESCRIPTION: Rubella, commonly known as German measles, is a communicable viral disease transmitted by contact with respiratory secretions and aerosolized droplets of the secretions. The incubation period is 14 to 21 days. This disease produces a pink, macular rash that disappears in 2 to 3 days. Rubella infection induces immunoglobulin (Ig) G and IgM antibody production. This test can determine current infection or immunity from past infection. Rubella serology is part of the TORCH (toxoplasmosis, other [congenital syphilis and viruses], rubella, cytomegalovirus, and herpes simplex type 2) panel routinely performed

on pregnant women. Fetal infection during the first trimester can affect all organs in the developing fetus and cause spontaneous abortion, fetal demise, or congenital defects. Up to 90% of infants born to mothers infected during the first trimester will develop a pattern of birth defects called congenital rubella syndrome (CRS). The rate of CRS decreases when infection occurs later in the gestational period. Ideally, the immune status of women of childbearing age should be ascertained before pregnancy, when vaccination can be administered to provide lifelong immunity. The presence of IgM antibodies indicates acute

infection. The presence of IgG antibodies indicates current or past infection. Susceptibility to rubella is indicated by a negative reaction. Many laboratories use a qualitative assay that detects the presence of both IgM and IgG rubella antibodies. IgM- and IgG-specific enzyme immunoassays are also available to help distinguish acute infection from immune status. Either the rubella-combined or IgG-specific assay should be used in routine prenatal testing of maternal serum.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of rubella infection
- Determine presence of rubella antibodies
- Determine susceptibility to rubella, particularly in pregnant women
- Perform as part of routine prenatal serological testing

POTENTIAL DIAGNOSIS

Positive findings in

- Rubella infection (past or present)

CRITICAL FINDINGS

A nonimmune status in pregnant patients may present significant health

consequences for the developing fetus if the mother is exposed to an infected individual.

Note and immediately report to the health-care provider (HCP) pregnant patients with rubella non-immune status.

It is essential that a critical finding be communicated immediately to the requesting HCP. A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Knowledge (<i>Related to new condition or diagnosis; lack of familiarity with or understanding</i>)	Lack of interest or questions; multiple questions; anxiety in relation to disease process and management	Teach the patient or parents that this is a disease that is accompanied by a rash and fever that will last for 2 to 3 days; explain to the patient and parents that the disease can be spread to others through

Problem	Signs & Symptoms	Interventions
<i>of disease and treatment)</i>		coughing and sneezing of the infected person; explain that MMR vaccination is recommended
Infection (<i>Related to exposure to viral organism from an infected individual)</i>	Fever and rash lasting 2 to 3 days; runny nose; headache; malaise	Explain that those infected can expose others to the virus from 1 week before the rash is present up to 2 weeks after the rash is gone; administer prescribed acetaminophen for headache and fever; discuss the fetal risk associated with infection during pregnancy (miscarriage, stillbirth); teach good hygiene
Grief (<i>Related to loss of potential child; loss secondary to rubella viral infection)</i>	Crying; report of grief; expression of emotional shock; psychological distress; disturbed sleep; loss of appetite; detachment; withdrawal; anger; blame; despair	Monitor for manifestation of grief (crying, loud grief vocalization); assess for the stage of grief; assess for the effectiveness of coping strategies; consider the cultural norm for grief expression; encourage sharing feelings; recommend grief support group; recommend psychosocial counseling as appropriate; administer prescribed medication to offset the emotional impact of grief (as appropriate); recognize the need to relive the loss

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can indicate rubella infection or immunity.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of exposure to rubella.
- ▶ Obtain a history of the patient's immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.

- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in detectable level of antibody. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is

important in providing psychological support before, during, and after the procedure.

- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Vaccination Considerations:** Record the date of the last menstrual period and determine the possibility of pregnancy prior to administration of rubella vaccine to female rubella-nonimmune patients. Instruct patient not to become pregnant for 1 mo after being vaccinated with the rubella vaccine to protect any fetus from contracting the disease and having serious birth defects. Instruct the patient on birth control methods to prevent pregnancy, if appropriate.

Delay rubella vaccination in pregnancy until after childbirth, and give immediately prior to discharge from the hospital.

- ▶ Recognize anxiety related to test results, and provide emotional support if results are positive and the patient is pregnant. Encourage the family to seek counseling if concerned with pregnancy termination. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Decisions regarding elective abortion should take place in the presence of both parents. Provide a nonjudgmental, nonthreatening atmosphere for discussing the risks and difficulties of delivering and raising a developmentally challenged infant as well as for exploring other options (e.g., termination of pregnancy or adoption). Educate the patient regarding access to counseling services, as appropriate.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Instruct the patient in isolation precautions during time of communicability or contagion.
- ▶ Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days.
- ▶ Provide information regarding vaccine-preventable diseases where indicated (e.g., rubella).
- ▶ Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac).
- ▶ Answer any questions or address any concerns voiced by the patient or family.

Expected Patient Outcomes:**Knowledge**

- States understanding about the stages of grief that may be experienced with a loss.
- Accurately describes the dose and frequency of acetaminophen to treat fever and headache.

Skills

- Demonstrates proficient hand washing—both family and patient
- Accurately describes precautions that should be taken to prevent the exposure of others to the infecting pathogen

Attitude

- Complies with the recommendation to provide a secondary blood sample up to 14 days after diagnosis
- Agrees to seek grief counseling to assist in coping with the loss of a potential child

RELATED MONOGRAPHS:

- Related tests include culture viral, CMV, rubeola, *Toxoplasma*, and varicella antibody.
- Refer to the Immune and Reproductive systems tables at the end of the book for related tests by body system.

Rubeola Antibodies

SYNONYM/ACRONYM: Measles serology.

COMMON USE: To assess for a rubeola infection or immunity.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Place separated serum into a standard transport tube within 2 hr of collection.

NORMAL FINDINGS: (Method: Enzyme immunoassay)

	IgM	Interpretation	IgG	Interpretation
Negative	0.79 AU or less	No significant level of detectable antibody	0.89 index or less	No significant level of detectable antibody; indicative of nonimmunity
Indeterminate	0.8–1.2 AU	Equivocal results; retest in 10–14 d	0.9–1.0 index	Equivocal results; retest in 10–14 d
Positive	1.3 AU or greater	Antibody detected; indicative of recent immunization, current or recent infection	1.1 index or greater	Antibody detected; indicative of immunization, current or past infection

DESCRIPTION: Measles is caused by a single-stranded ribonucleic acid (RNA) paramyxovirus that invades the respiratory tract and lymphoreticular tissues. It is transmitted by respiratory secretions and aerosolized droplets of the secretions. The incubation period is 10 to 11 days. Symptoms initially include conjunctivitis, cough, and fever. Koplik's spots develop 4 to 5 days later, followed by papular eruptions, body rash, and lymphadenopathy. The presence of immunoglobulin (Ig) M antibodies indicates acute infection. The presence of IgG antibodies indicates current or past infection. Susceptibility to measles is indicated by a negative reaction. Many laboratories use a qualitative assay that detects the presence of both IgM and IgG rubeola antibodies. IgM- and IgG-specific enzyme immunoassays are also available to help distinguish acute infection from immune status.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine resistance to or protection against measles virus
- Differential diagnosis of viral infection, especially in pregnant women with a history of exposure to measles

POTENTIAL DIAGNOSIS

Positive findings in

- Measles infection

CRITICAL FINDINGS: N/A

INTERFERING FACTORS: N/A

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test is to assess for measles.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of exposure to measles.
- ▶ Obtain a history of the patient's immune system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that several tests may be necessary to confirm the diagnosis. Any individual positive result should be repeated in 7 to 14 days to monitor a change in detectable levels of antibody. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions, unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ **Vaccination Considerations:** Record the date of the last menstrual period and determine the possibility of pregnancy prior to administration of rubeola vaccine to female rubeola-nonimmune patients. Instruct patient not to become pregnant for 1 mo after being vaccinated with the rubeola vaccine to protect any fetus from contracting the disease. The danger of contracting measles while pregnant include the possibilities of miscarriage, stillbirth, or

preterm delivery. Instruct the patient on birth control methods to prevent pregnancy, if appropriate. Delay rubella vaccination in pregnancy until after childbirth, and give immediately prior to discharge from the hospital.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Instruct the patient in isolation precautions during time of communicability or contagion. Emphasize the need to return to have a convalescent blood sample taken in 7 to 14 days. Provide information regarding vaccine-preventable diseases where indicated (e.g., measles). Provide contact information, if desired, for the Centers for Disease Control and Prevention (www.cdc.gov/vaccines/vpd-vac). Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include culture viral, rubella, and varicella.
- ▶ Refer to the Immune System table at the end of the book for related tests by body system.

Schirmer Tear Test

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess tear duct function.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: The tear film, secreted by the lacrimal, Krause, and Wolfring glands, covers the surface of the eye. Blinking spreads tears over the eye and moves them toward an opening in the lower eyelid known as the punctum. Tears drain through the punctum into the nasolacrimal duct and into the nose. The Schirmer tear test simultaneously tests both eyes to assess lacrimal gland function by determining the amount of moisture accumulated on standardized filter paper or strips held against the conjunctival sac of each eye. The Schirmer test measures both reflex and basic secretion of tears. The Schirmer II test measures basic tear secretion and is used to evaluate the accessory glands of Krause and Wolfring. The Schirmer test is performed by instilling a topical anesthetic before insertion of filter paper. The topical anesthetic inhibits reflex tearing of major lacrimal glands by the filter paper, allowing testing of the accessory glands. The Schirmer II test is performed by irritating the nostril with a cotton swab to stimulate tear production.

This procedure is contraindicated for: N/A

INDICATIONS

- Assess adequacy of tearing for contact lens comfort and for successful LASIK surgery
- Assess suspected tearing deficiency

POTENTIAL DIAGNOSIS

Normal findings in

- 10 mm of moisture on test strip after 5 min. It may be slightly less than 10 mm in elderly patients.

Abnormal findings in

- Tearing deficiency related to aging, dry eye syndrome, or Sjögren's syndrome
- Tearing deficiency secondary to leukemia, lupus erythematosus, lymphoma, rheumatoid arthritis, or scleroderma

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair the results of the examination

- Inability of the patient to remain still and cooperative during the test may interfere with the test results.
- Rubbing or squeezing the eyes may affect results.
- Clinical conditions such as pregnancy may temporarily result in dry eye due to hormonal fluctuations.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating tear duct function.
- ▶ Obtain a history of the patient's complaints, including a list of known

allergens, especially topical anesthetic eye drops.

- ▶ Obtain a history of the patient's known or suspected vision loss; changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- ▶ Obtain a history of the patient's symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate. Instruct the patient regarding the importance of keeping the eyes open for the test.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that no pain will be experienced during the test, but there may be moments of discomfort. Explain to the patient that some discomfort may be experienced after the test when the numbness wears off from anesthetic drops administered prior to the test. Inform the patient that the test is performed by a health-care provider (HCP) and takes about 15 min to complete.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications:

Corneal abrasion caused by patient rubbing the eye before topical anesthetic has worn off.

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.

- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Seat the patient comfortably. Instruct the patient to look straight ahead, keeping the eyes open and unblinking.
- ▶ Instill topical anesthetic in each eye, as ordered, and provide time for it to work. Topical anesthetic drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (gray, semitransparent area of the eyeball where the cornea and sclera meet). Neither the dropper nor the bottle should touch the eyelashes. Insert a test strip in each eye. The strip should be folded over the midportion of both lower eyelids. Instruct the patient to gently close both eyes for approximately 5 minutes then remove the strips and measure the amount of moisture on the strips.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Assess for corneal abrasion caused by patient rubbing the eye before topical anesthetic has worn off.
- ▶ Instruct the patient to avoid rubbing the eyes for 30 min after the procedure.
- ▶ If appropriate, instruct the patient not to reinsert contact lenses for 2 hr.
- ▶ Recognize anxiety related to test results, and be supportive of pain related to decreased lacrimation or inflammation. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Provide contact information, if desired, for a general patient education Web site on the topic of eye care (e.g., www.allaboutvision.com).
- ▶ Reinforce information given by the patient's HCP regarding further testing,

treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.

- ▶ Instruct the patient in the use of any ordered medications. Explain the importance of adhering to the therapy regimen. As appropriate, instruct the patient in significant side effects and systemic reactions associated with the prescribed medication. Encourage him or her to review corresponding literature provided by a pharmacist.
- ▶ Depending on the results of this procedure, additional testing may be

performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antibodies ANA, refraction, rheumatoid factor, and slit-lamp biomicroscopy.
- ▶ Refer to the Ocular System table at the end of the book for related tests by body system.

Semen Analysis

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess for male infertility related to disorders such as obstruction, testicular failure, and atrophy.

SPECIMEN: Semen from ejaculate specimen collected in a clean, dry, glass container known to be free of detergent. The specimen container should be kept at body temperature (37°C) during transportation.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination)

Test	Normal Result
Volume	2–5 mL
Color	White or opaque
Appearance	Viscous (pours in droplets, not clumps or strings)
Clotting and liquefaction	Complete in 15–20 min, rarely over 60 min
pH	7.2–8
Sperm count	Greater than 15 million/mL
Total sperm count	Greater than 39 million/ejaculate
Motility	At least 40% at 60 min
Vitality (membrane intact)	At least 58%
Morphology	Greater than 25–30% normal oval-headed forms

The number of normal sperm is calculated by multiplying the total sperm count by the percentage of normal forms.

DESCRIPTION: Semen analysis is a valid measure of overall male fertility. Semen contains a combination of elements produced by various parts of the male reproductive system. Spermatozoa are produced in the testes and account for only a small volume of seminal fluid. Fructose and other nutrients are provided by fluid produced in the seminal vesicles. The prostate gland provides acid phosphatase and other enzymes required for coagulation and liquefaction of semen. Sperm motility depends on the presence of a sufficient level of ionized calcium. If the specimen has an abnormal appearance (e.g., bloody, oddly colored, turbid), the patient may have an infection. Specimens can be tested with a leukocyte esterase strip to detect the presence of white blood cells.

This procedure is contraindicated for: N/A

INDICATIONS

- Assist in the diagnosis of azoospermia and oligospermia
- Evaluate infertility
- Evaluate effectiveness of vasectomy
- Evaluate the effectiveness of vasectomy reversal
- Support or disprove sterility in paternity suit

POTENTIAL DIAGNOSIS

There is marked intraindividual variation in sperm count. Indications of suboptimal fertility should be investigated by serial analysis of two to three samples collected over several months. If abnormal results are obtained, additional testing may be requested.

Abnormality	Test Ordered	Normal Result
Decreased count	Fructose	Present (greater than 150 mg/dL)
Decreased motility with clumping	Male antisperm antibodies	Absent
Normal semen analysis with infertility	Female antisperm antibodies	Absent

Increased in: N/A

Decreased in

- Hyperpyrexia (**unusual and abnormal elevation in body temperature may result in insufficient sperm production**)
- Infertility (**related to insufficient production of sperm**)
- Obstruction of ejaculatory system
- Orchitis (**insufficient sperm production usually related to viral infection, rarely bacterial infection**)

- Postvasectomy period (**related to obstruction of the vas deferens**)
- Primary and secondary testicular failure (**congenital, as in Klinefelter's syndrome, or acquired via infection**)
- Testicular atrophy (e.g., recovery from mumps)
- Varicocele (**abnormal enlargement of the blood vessels in the scrotal area eventually damages testicular tissue and affects sperm production**)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs and substances that may decrease sperm count include arsenic, azathioprine, cannabis, cimetidine, cocaine, cyclophosphamide, estrogens, fluoxymesterone, ketoconazole, lead, methotrexate, methyltestosterone, nitrofurantoin, nitrogen mustard, procarbazine, sulfa-salazine, and vincristine.
- Testicular radiation may decrease sperm counts.
- Cigarette smoking is associated with decreased production of semen.
- Caffeine consumption is associated with increased sperm density and number of abnormal forms.
- Delays in transporting the specimen and failure to keep the specimen warm during transportation are the most common reasons for specimen rejection.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assess for infertility.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's immune and reproductive systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Review the procedure with the patient. Instruct the patient to refrain from any sexual activity for 3 days before

specimen collection. Instruct the patient to bring the specimen to the laboratory within 30 to 60 min of collection and to keep the specimen warm (close to body temperature) during transportation. The requesting health-care provider (HCP) usually provides the patient with instructions for specimen collection. Address concerns about pain and explain that there should be no discomfort during the procedure.

- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

Ejaculated Specimen

- ▶ Ideally, the specimen is obtained by masturbation in a private location close to the laboratory. In cases in which the patient expresses psychological or religious concerns about masturbation, the specimen can be obtained during coitus interruptus, through the use of a condom, or through postcoital collection of samples from the cervical canal and vagina of the patient's sexual partner. The patient should be warned about the possible loss of the sperm-rich portion of the sample if coitus interruptus is the collection approach. If a condom is used, the patient must be instructed to carefully wash and dry the condom completely before use to prevent contamination of the specimen with spermicides.

Cervical Vaginal Specimen

- ▶ Assist the patient's partner to the lithotomy position on the examination

table. A speculum is inserted, and the specimen is obtained by direct smear or aspiration of saline lavage.

Specimens Collected From Skin or Clothing

- ▶ Dried semen may be collected by sponging the skin with a gauze soaked in saline or by soaking the material in a saline solution.

General

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Recognize anxiety related to test results. Provide a supportive, nonjudgmental environment when assisting a patient through the process of fertility testing. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.

Encourage the patient or family to seek counseling and other support services if concerned with infertility.

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include antisperm antibodies, cancer antigens, Chlamydia group antibodies, estradiol, FSH, hysterosalpingography, laparoscopy gynecologic, LH, testosterone, and US scrotal.
- ▶ Refer to the Immune and Reproductive systems tables at the end of the book for related tests by body system.

Sialography

SYNONYM/ACRONYM: Salivary gland studies.

COMMON USE: To assess parotid, submaxillary, sublingual, and submandibular ducts for structure, tumors, and inflammation related to pain, swelling, and tenderness.

AREA OF APPLICATION: Base of the tongue, mandible, parotid gland, submandibular gland, sublingual gland.

CONTRAST: Water-soluble iodinated contrast medium.

DESCRIPTION: Sialography is the radiographic visualization of the salivary glands and ducts. These glands secrete saliva into the mouth, and there are three pairs

of salivary glands: the parotid, the submandibular, and the sublingual. Sialography involves the introduction of a water-soluble contrast agent into the orifices of the

salivary gland ducts with a small cannula, followed by a series of radiographic images. The evaluation of the salivary glands is usually done with computed tomography or magnetic resonance imaging; however, sialography is the method of choice when a definite diagnosis is required for pathology such as sialadenitis (inflammation of the salivary glands) or if the oral component of Sjögren's syndrome is a concern.

This procedure is contraindicated for

-  Patients who are pregnant or suspected of being pregnant, unless the potential benefits of a procedure using radiation far outweigh the risk of radiation exposure to the fetus and mother.
-  Patients with conditions associated with adverse reactions to contrast medium (e.g., asthma, food allergies, or allergy to contrast medium).

Although patients are still asked specifically if they have a known allergy to iodine or shellfish, it has been well established that the reaction is not to iodine, in fact an actual iodine allergy would be very problematic because iodine is required for the production of thyroid hormones. In the case of shellfish, the reaction is to a muscle protein called tropomyosin; in the case of iodinated contrast medium, the reaction is to the noniodinated part of the contrast molecule. Patients with a known hypersensitivity to the medium may benefit from premedication with corticosteroids and diphenhydramine; the use of nonionic contrast or an alternative noncontrast imaging study, if available, may be considered for patients who have severe

asthma or who have experienced moderate to severe reactions to ionic contrast medium.

-  Patients with conditions associated with preexisting renal insufficiency (e.g., renal failure, single kidney transplant, nephrectomy, diabetes, multiple myeloma, treatment with aminoglycosides and NSAIDs) ***because iodinated contrast is nephrotoxic.***
-  Elderly and compromised patients who are chronically dehydrated before the test ***because of their risk of contrast-induced renal failure.***
-  Patients with bleeding disorders ***because the puncture site may not stop bleeding.***

INDICATIONS

- Evaluate the presence of calculi in the salivary glands
- Evaluate the presence of tumors in the salivary glands
- Evaluate narrowing of the salivary ducts

POTENTIAL DIAGNOSIS

Normal findings in

- Normal salivary ducts with no indication of gland abnormalities

Abnormal findings in

- Calculi
- Fistulas
- Mixed parotid tumors
- Sialectasia (dilation of a duct)
- Strictures of the ducts

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Inability of the patient to cooperate or remain still during the test because of age, significant pain, or mental status may interfere with the test results.

Other considerations

- Consultation with an HCP should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size. **Pediatric Imaging** Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).
- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record the level of radiation exposure.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient that this procedure can assist in assessing duct glands in the neck and mouth.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex, anesthetics, contrast medium, or sedatives.
- ▶ Obtain a history of the patient's endocrine system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Record the date of last menstrual period and determine the possibility of pregnancy in perimenopausal women.

- ▶ Obtain a list of the patient's current medications, including anticoagulants, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ If iodinated contrast medium is scheduled to be used in patients receiving metformin (Glucophage) for non-insulin-dependent (type 2) diabetes, the drug should be discontinued on the day of the test and continue to be withheld for 48 hr after the test. Iodinated contrast can temporarily impair kidney function, and failure to withhold metformin may indirectly result in drug-induced lactic acidosis, a dangerous and sometimes fatal side effect of metformin **related to renal impairment that does not support sufficient excretion of metformin**.
- ▶ Instruct the patient to remove dentures or removable bridgework prior to examination.
- ▶ Review the procedure with the patient. Inform the patient that the procedure is usually done with the patient awake and laying on a table. Address concerns about pain and explain that the patient may be asked to suck on a lemon slice to dilate the salivary orifice, and a local anesthetic spray or liquid may be applied to the throat to ease with insertion of the cannula. Inform the patient that the procedure is performed in a radiology department by a health-care provider (HCP) specializing in this procedure, with support staff, and takes approximately 15 to 30 min.
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.
- ▶ **Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.**

INTRATEST:

Potential Complications:

Complications are rare but do include risk for allergic reaction **related to contrast reaction** or bleeding from the

puncture site **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners.**

- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has removed dentures and removable bridgework prior to the procedure.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of severe allergic reactions to any substance or drug. Use nonionic contrast medium for the procedure.
- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Place the patient in the supine position on an examination table. Instill ordered topical anesthetic in the throat, as ordered, and allow time for it to work.
- ▶ The salivary duct is located and dilated. Following insertion of the cannula, the contrast medium is injected, and a series of images is taken. Delayed images may be taken to examine the ducts in cases of ductal obstruction.
- ▶ Ask the patient to inhale deeply and hold his or her breath while the x-ray images are taken, and then to exhale after the images are taken.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or cannula.
- ▶ Observe/assess the needle/cannula insertion site for bleeding or inflammation.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the

requesting HCP, who will discuss the results with the patient.

- ▶ Instruct the patient to wait until the numbness in the throat wears off before attempting to eat or drink following the procedure.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the needle/cannula insertion site for bleeding or inflammation.
- ▶ Instruct the patient in the care and assessment of the site.
- ▶ Instruct the patient to apply cold compresses to the puncture site as needed to reduce discomfort or edema.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be needed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include CT brain, MRI brain, and radiography bone.
- ▶ Refer to the Endocrine System table at the end of the book for related tests by body system.

Sickle Cell Screen

SYNONYM/ACRONYM: Sickle cell test.

COMMON USE: To assess for hemoglobin S to assist in diagnosing sickle cell anemia.

SPECIMEN: Whole blood (1 mL) collected in a lavender-top (EDTA) tube.

NORMAL FINDINGS: (Method: Hemoglobin high-salt solubility) Negative.

DESCRIPTION: The sickle cell screen is one of several screening tests for a group of hereditary hemoglobinopathies. The test is positive in the presence of rare sickling hemoglobin (Hgb) variants such as Hgb S and Hgb C Harlem. Electrophoresis and high-performance liquid chromatography as well as molecular genetics testing for beta-globin mutations can also be used to identify Hgb S. Hgb S results from an amino acid substitution during Hgb synthesis whereby valine replaces glutamic acid. Hemoglobin C Harlem results from the substitution of lysine for glutamic acid. Individuals with sickle cell disease have chronic anemia because the abnormal Hgb is unable to carry oxygen. The red blood cells of affected individuals are also abnormal in shape, resembling a crescent or sickle rather than the normal disk shape. This abnormality, combined with cell-wall rigidity, prevents the cells from passing through smaller blood vessels. Blockages in blood vessels result in hypoxia, damage, and pain. Individuals with the sickle cell trait do not have the clinical manifestations of the disease but may pass the disease on to children if the other parent has the trait (or the disease) as well.

This procedure is contraindicated for: N/A

INDICATIONS

- Detect sickled red blood cells
- Evaluate hemolytic anemias

POTENTIAL DIAGNOSIS

Positive findings in Deoxygenated Hgb S is insoluble in the presence of a high-salt solution and will form a cloudy turbid suspension when present.

- Combination of Hgb S with other hemoglobinopathies
- Hgb C Harlem anemia
- Sickle cell anemia
- Sickle cell trait
- Thalassemias

Negative findings in: N/A

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase sickle cells in vitro include prostaglandins.
- A positive test does not distinguish between the sickle trait and sickle cell anemia; to make this determination, follow-up testing by Hgb electrophoresis should be performed.
- False-negative results may occur in children younger than 3 mo of age.
- False-negative results may occur in patients who have received a

recent blood transfusion before specimen collection, as a result of the dilutional effect.

- False-positive results may occur in patients without the trait or disease who have received a blood transfusion from a sickle cell–positive donor; this effect can last for 4 mo after the transfusion.
- Test results are unreliable if the patient has pernicious anemia or polycythemia.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in diagnosing anemia.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's hematopoietic system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.
- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.
- ▶ Advise the patient with sickle cell disease to avoid situations in which hypoxia may occur, such as strenuous exercise, staying at high altitudes, or traveling in an unpressurized aircraft. Obstetric and surgical patients with sickle cell anemia are at risk for hypoxia and therefore require close observation: Obstetric patients are at risk for hypoxia during the stress of labor and delivery, and surgical patients may become hypoxic while under general anesthesia.
- ▶ Recognize anxiety related to test results, and offer support, as appropriate. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate. Educate the patient regarding

access to counseling services (www.sicklecelldisease.org).

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that further testing may be indicated if results are positive. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in

therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include biopsy bone marrow, CBC, CBC RBC morphology, CBC RBC indices, ESR, Hgb electrophoresis, hemosiderin, LAP, MRI musculoskeletal, newborn screening, RBC cholinesterase, and US spleen.
- ▶ Refer to the Hematopoietic System table at the end of the book for related tests by body system.

Slit-Lamp Biomicroscopy

SYNONYM/ACRONYM: Slit-lamp examination.

COMMON USE: To detect abnormalities in the external and anterior eye structures to assist in diagnosing disorders such as corneal injury, hemorrhage, ulcers, and abrasion.

AREA OF APPLICATION: Eyes.

CONTRAST: N/A.

DESCRIPTION: This noninvasive procedure is used to visualize the anterior portion of the eye and its parts, including the eyelids and eyelashes, sclera, conjunctiva, cornea, iris, lens, and anterior chamber, and to detect pathology of any of these areas of the eyes. The slit lamp has a binocular microscope and light source that can be adjusted to examine the fluid, tissues, and structures of the eyes. For example, slit lamp ophthalmoscopy can be performed using the microscope part of the slit lamp and a special lens placed close to the eye to examine the retina, optic disc, choroid, and

blood vessels in the back or fundus of the eye. Ophthalmoscopy is helpful in the identification of retinal detachment, diseases such as glaucoma that affect the movement of eye fluid, or diseases that affect the blood vessels in the eyes such as hypertension and diabetes. Special attachments to the slit lamp are used for special studies and more detailed views of specific areas. Dilating drops or mydriatics may be used to enlarge the pupil in order to allow the examiner to see the eye in greater detail. Mydriatics work either by temporarily paralyzing the muscle that makes the pupil smaller or

by stimulating the iris dilator muscle. Blue or hazel eyes dilate faster than brown eyes.

This procedure is contraindicated for

-  Patients with narrow-angle glaucoma if pupil dilation is performed; dilation can initiate a severe and sight-threatening open-angle attack.
-  Patients with allergies to mydriatics if pupil dilation using mydriatics is performed.

INDICATIONS

- Detect conjunctival and corneal injuries by foreign bodies and determine if ocular penetration or anterior chamber hemorrhage is present
- Detect corneal abrasions, ulcers, or abnormal curvatures (keratoconus)
- Detect deficiency in tear formation indicative of lacrimal dysfunction causing dry eye disease that can lead to corneal erosions or infection
- Detect lens opacities indicative of cataract formation
- Determine the presence of blepharitis, conjunctivitis, hordeolum, entropion, ectropion, trachoma, scleritis, and iritis
- Evaluate the fit of contact lenses

POTENTIAL DIAGNOSIS

Normal findings in

- Normal anterior tissues and structures of the eyes

Abnormal findings in

- Blepharitis
- Conjunctivitis
- Corneal abrasions
- Corneal foreign bodies
- Corneal ulcers
- Diabetes
- Entropion

- Entropion
- Glaucoma
- Hordeolum
- Iritis
- Keratoconus (abnormal curvatures)
- Lens opacities
- Scleritis
- Trachoma

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Inability of the patient to cooperate and remain still during the procedure because of age, significant pain, or mental status may interfere with the test results.
- Failure to follow medication restrictions before the procedure may cause the procedure to be canceled or repeated.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this procedure can assist in evaluating the structures of the eye.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially mydriatics if dilation is to be performed.
- ▶ Obtain a history of the patient's known or suspected vision loss, changes in visual acuity, including type and cause; use of glasses or contact lenses; eye conditions with treatment regimens; eye surgery; and other tests and procedures to assess and diagnose visual deficit.
- ▶ Obtain a history of the patient's symptoms and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).

- ▶ Instruct the patient to remove contact lenses or glasses, as appropriate, unless the study is being done to check the fit and effectiveness of the contact lenses. Instruct the patient regarding the importance of keeping the eyes open for the test.
- ▶ Review the procedure with the patient. Address concerns about pain and explain that mydriatics, if used, may cause blurred vision and sensitivity to light. There may also be a brief stinging sensation when the drop is put in the eye. Inform the patient that a health-care provider (HCP) performs the test in a quiet, darkened room, and that to evaluate both eyes, the test can take up 30 min (including time for the pupils to dilate before the test is actually performed).
- ▶ **Sensitivity to social and cultural issues**, as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food or fluid restrictions unless by medical direction.
- ▶ Instruct the patient to withhold eye medications (particularly miotic eye drops which may constrict the pupil preventing a clear view of the fundus and mydriatic eyedrops in order to avoid instigation of an acute open angle attack in patients with narrow angle glaucoma) for at least 1 day prior to the procedure.
- ▶ Ensure that the patient understands that he or she must refrain from driving until the pupils return to normal (about 4 hr) after the test and has made arrangements to have someone else be responsible for transportation after the test.

INTRATEST:

Potential Complications:

- ▶ Dilation can initiate a severe and sight-threatening open-angle attack in patients with narrow-angle glaucoma.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient.
- ▶ Ensure that the patient has complied with medication restrictions and pre-testing preparations; assure that eye

medications, especially mydriatics, have been restricted for at least 1 day prior to the procedure.

- ▶ Instruct the patient to cooperate fully and to follow directions. Ask the patient to remain still during the procedure because movement produces unreliable results.
- ▶ Seat the patient comfortably. If dilation is to be performed, administer the ordered mydriatic to each eye and repeat in 5 to 15 min. Drops are placed in the eye with the patient looking up and the solution directed at the six o'clock position of the sclera (white of the eye) near the limbus (gray, semitransparent area of the eyeball where the cornea and sclera meet). Neither dropper nor bottle should touch the eyelashes.
- ▶ Ask the patient to place the chin in the chin rest and gently press the forehead against the support bar.
- ▶ The HCP places the slit lamp in front of the patient's eyes in line with the examiner's eyes. The external structures of the eyes are inspected with the special bright light and microscope of the slit lamp. The light is then directed into the patient's eyes to inspect the anterior fluids and structures and is adjusted for shape, intensity, and depth needed to visualize these areas. Magnification of the microscope is also adjusted to optimize visualization of the eye structures.
- ▶ Special attachments and procedures can also be used to obtain further diagnostic information about the eyes. These may include, for example, a camera to photograph specific parts, gonioscopy to determine anterior chamber closure, and a cobalt-blue filter to detect minute corneal scratches, breaks, and abrasions with corneal staining.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual medications, as directed by the HCP.
- ▶ Recognize anxiety related to test results, and encourage the family to recognize and be supportive of impaired

activity related to vision loss, anticipated loss of driving privileges, or the possibility of requiring corrective lenses (self-image). Discuss the implications of the abnormal test results on the patient's lifestyle. Provide contact information, if desired, for a general patient education Web site on the topic of eye care (e.g., www.allaboutvision.com).

- Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Inform the patient that visual acuity and responses to light may change. Suggest that the patient wear dark glasses after the test until the pupils return to normal size. Answer any questions or address any concerns voiced by the patient or family.

Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- Related tests include color perception test, fluorescein angiography, gonioscopy, intraocular muscle function, intraocular pressure, nerve fiber analysis, refraction, Schirmer tear test, and visual field testing.
- Refer to the Ocular System table at the end of the book for related tests by body system.

Sodium, Blood

SYNONYM/ACRONYM: Serum Na⁺.

COMMON USE: To assess electrolyte balance related to hydration levels and disorders such as diarrhea and vomiting and to monitor the effect of diuretic use.

SPECIMEN: Serum (1 mL) collected in a gold-, red-, or red/gray-top tube. Plasma (1 mL) collected in a green-top (heparin) tube is also acceptable.

NORMAL FINDINGS: (Method: Ion-selective electrode)

Age	Conventional & SI Units
Cord	126–166 mEq/L or mmol/L
1–12 hr	124–156 mEq/L or mmol/L
12–24 hr	132–159 mEq/L or mmol/L
24–48 hr	134–160 mEq/L or mmol/L
48–72 hr	139–162 mEq/L or mmol/L
Newborn	135–145 mEq/L or mmol/L
7 d–1 mo	134–144 mEq/L or mmol/L
2 mo–5 mo	134–142 mEq/L or mmol/L
6 mo–1 yr	133–142 mEq/L or mmol/L
Child-Adult–older adult	135–145 mEq/L or mmol/L

Note: Older adults are at increased risk for both hypernatremia and hyponatremia. Diminished thirst, illness, and lack of mobility are common causes for hypernatremia in older adults. There are multiple causes of hyponatremia in older adults, but the most common factor may be related to the use of thiazide diuretics.

DESCRIPTION: Electrolytes dissociate into electrically charged ions when dissolved. Cations, including sodium, carry a positive charge. Body fluids contain approximately equal numbers of anions and cations, although the nature of the ions and their mobility differs between the intracellular and extracellular compartments. Both types of ions affect the electrical and osmolar functions of the body. Electrolyte quantities and the balance among them are controlled by oxygen and carbon dioxide exchange in the lungs; absorption, secretion, and excretion of many substances by the kidneys; and secretion of regulatory hormones by the endocrine glands. Sodium is the most abundant extracellular cation that together with chloride and bicarbonate participate in a number of essential functions to include maintaining the osmotic pressure of extracellular fluid, regulating renal retention and excretion of water, maintaining acid-base balance, regulating potassium levels, stimulating neuromuscular reactions, and maintaining systemic blood pressure. *Hypernatremia* (elevated sodium level) occurs when there is excessive water loss or abnormal retention of sodium. *Hyponatremia* (low sodium level) occurs when there is inadequate sodium retention or inadequate intake.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine whole-body stores of sodium, because the ion is predominantly extracellular

- Monitor the effectiveness of drug therapy, especially diuretics, on serum sodium levels

POTENTIAL DIAGNOSIS

Increased in

- Azotemia (*related to increased renal retention*)
- Burns (*hemoconcentration related to excessive loss of free water*)
- Cushing's disease
- Dehydration
- Diabetes (*dehydration related to frequent urination*)
- Diarrhea (*related to water loss in excess of salt loss*)
- Excessive intake
- Excessive saline therapy (*related to administration of IV fluids*)
- Excessive sweating (*related to loss of free water, which can cause hemoconcentration*)
- Fever (*related to loss of free water through sweating*)
- Hyperaldosteronism (*related to excessive production of aldosterone, which increases renal absorption of sodium and increases blood levels*)
- Lactic acidosis (*related to diabetes*)
- Nasogastric feeding with inadequate fluid (*related to dehydration and hemoconcentration*)
- Vomiting (*related to dehydration*)

Decreased in

- Central nervous system disease
- Congestive heart failure (*diminished renal blood flow due to reduced cardiac capacity decreases urinary excretion and increases blood sodium levels*)
- Cystic fibrosis (*related to loss from chronic diarrhea; poor intestinal absorption*)
- Excessive antidiuretic hormone production (*related to excessive loss through renal excretion*)

- Excessive use of diuretics (*related to excessive loss through renal excretion; renal absorption is blocked*)
- Hepatic failure (*hemodilution related to fluid retention*)
- Hypoproteinemia (*related to fluid retention*)
- Insufficient intake
- IV glucose infusion (*hypertonic glucose draws water into extracellular fluid and sodium is diluted*)
- Mineralocorticoid deficiency (Addison's disease) (*related to inadequate production of aldosterone, which results in decreased absorption by the kidneys*)
- Nephrotic syndrome (*related to decreased ability of renal tubules to reabsorb sodium*)

CRITICAL FINDINGS

- **Hyponatremia:** Less than 120 mEq/L or mmol/L (SI: Less than 120 mmol/L)
- **Hypernatremia:** Greater than 160 mEq/L or mmol/L (SI: Greater than 160 mmol/L)

Consideration may be given to verifying the critical findings before action is taken. Policies vary among facilities and may include requesting immediate recollection and retesting by the laboratory or retesting using a rapid Point of Care instrument at the bedside.

Note and immediately report to the health-care provider (HCP) any critically increased or decreased values and related symptoms especially fluid imbalance.

It is essential that a critical finding be communicated immediately to the requesting health-care provider (HCP). A listing of these findings varies among facilities.

Timely notification of a critical finding for lab or diagnostic studies is a role expectation of the professional nurse. Notification processes will vary

among facilities. Upon receipt of the critical value the information should be read back to the caller to verify accuracy. Most policies require immediate notification of the primary HCP, Hospitalist, or on-call HCP. Reported information includes the patient's name, unique identifiers, critical value, name of the person giving the report, and name of the person receiving the report. Documentation of notification should be made in the medical record with the name of the HCP notified, time and date of notification, and any orders received. Any delay in a timely report of a critical finding may require completion of a notification form with review by Risk Management.

Signs and symptoms of hyponatremia include confusion, irritability, convulsions, tachycardia, nausea, vomiting, and loss of consciousness. Possible interventions include maintenance of airway, monitoring for convulsions, fluid restriction, and performance of hourly neurological checks. Administration of saline for replacement requires close attention to serum and urine osmolality.

Signs and symptoms of hypernatremia include restlessness, intense thirst, weakness, swollen tongue, seizures, and coma. Possible interventions include treatment of the underlying cause of water loss or sodium excess, which includes sodium restriction and administration of diuretics combined with IV solutions of 5% dextrose in water (D₅W).

INTERFERING FACTORS

- Drugs that may increase serum sodium levels include anabolic steroids, angiotensin, bicarbonate, carbenoxolone, cisplatin, corticotropin, cortisone, gamma globulin, and mannitol.
- Drugs that may decrease serum sodium levels include amphotericin B, bicarbonate, cathartics (excessive use), chlorpropamide,

chlorthalidone, diuretics, ethacrynic acid, fluoxetine, furosemide, laxatives (excessive use), methyclothiazide, metolazone, nifedipine, quinethazone, theophylline (IV infusion), thiazides, and triamterene.

- Specimens should never be collected above an IV line because of the

potential for dilution when the specimen and the IV solution combine in the collection container, falsely decreasing the result. There is also the potential of contaminating the sample with the substance of interest, if it is present in the IV solution, falsely increasing the result.

NURSING IMPLICATIONS AND PROCEDURE

Potential Nursing Problems:

Problem	Signs & Symptoms	Interventions
Fluid volume <i>(Related to an excess or deficit of sodium associated with electrolyte disturbance and associated disease process)</i>	Deficient: decreased urinary output, fatigue, sunken eyes, dark urine, decreased blood pressure, increased heart rate, and altered mental status. Overload: edema, shortness of breath, increased weight, ascites, rales, rhonchi, and diluted laboratory values	Record daily weight and monitor trends; record accurate intake and output; collaborate with physician with administration of IV fluids to support hydration; monitor laboratory values that reflect alterations in fluid status (potassium, blood urea nitrogen, creatinine, calcium, hemoglobin, and hematocrit, sodium); manage underlying cause of fluid alteration; monitor urine characteristics and respiratory status; establish baseline assessment data; collaborate with physician to adjust oral and IV fluids to provide optimal hydration status; administer replacement electrolytes as ordered; adjust diuretics as appropriate
Electrolyte imbalance: Excess <i>(Related to excess fluid loss, watery diarrhea; inability to take oral fluids; excess perspiration;</i>	Excess: furrowed tongue; dry mouth; headache; dry skin; seizures; coma; tachycardia; hypotension; vascular collapse; restlessness; increased urine; output; weight gain;	Correlate sodium imbalance with disease process, nutritional intake, renal function, medications; monitor ECG status; monitor for respiratory changes; minimize metabolic complications; provide a safe environment to prevent injury; collaborate with the

(table continues on page 1400)

Problem	Signs & Symptoms	Interventions
<p>large area burns; excess sodium intake)</p> <p>Deficit (<i>Related to excess sodium loss through kidneys; diuretic use; adrenal insufficiency with altered cortisol and aldosterone production; vomiting and diarrhea; heart failure; renal failure; cirrhosis</i>)</p>	<p>altered mental status. Deficit: muscle cramps; weakness; fatigue; confusion; anorexia; nausea; vomiting; abdominal cramps; diarrhea; headache; depression; personality changes; irritability; muscle twitching; coma; anxiety</p>	<p>pharmacist and HCP for appropriate pharmacologic interventions; adjust medication dosage to compensate for renal impairment; collaborate with dietician for dietary modifications; use renal dialysis as necessary; reduce or increase intake of high-sodium foods and salts; if deficit avoid thiazide diuretics; if excess use diuretics to increase sodium excretion; if excess use IV fluids to remedy dehydration; if excess use IV NACL infusion as prescribed</p>
<p>Diarrhea (<i>Related to gastric irritation from diet or disease; stress; drug side effect; laxative abuse; malabsorption; alcohol abuse; chemotherapy; enteric infections</i>)</p>	<p>Abdominal pain; cramping; frequent stools that exceed three per day; watery stools; gastrointestinal urgency; hyperactive bowel sounds</p>	<p>Assess bowel sounds; send stool for culture as ordered; assess for food intolerances that can irritate the gastrointestinal tract; review tolerance to dairy products; check for a history of gastrointestinal disease or surgery; ask about foreign travel; administer prescribed antidiarrheal; evaluate and replace lost fluids; consider dietary bulk</p>
<p>Confusion (<i>Related to sodium excess or deficit secondary to metabolic alterations, disease process, or burns</i>)</p>	<p>Disorganized thinking, restlessness, irritability, altered concentration and attention span, changeable mental function over the day, hallucinations</p>	<p>Treat the medical condition; correlate confusion with the need to reverse altered electrolytes; evaluate medications; prevent falls and injury through appropriate use of postural support, bed alarm, or the restraints; consider pharmacological interventions; record accurate intake and output to assess fluid status</p>

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating electrolyte balance.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's cardiovascular, endocrine, and genitourinary systems; symptoms; and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Inform the patient that specimen collection takes approximately 5 to 10 min. Address concerns about pain and explain that there may be some discomfort during the venipuncture.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:**Potential Complications:** N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions. Direct the patient to breathe normally and to avoid unnecessary movement.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection. Perform a venipuncture.
- ▶ Remove the needle and apply direct pressure with dry gauze to stop bleeding. Observe/assess venipuncture site for bleeding or hematoma formation and secure gauze with adhesive bandage.

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ **Nutritional Considerations:** Evaluate the patient for signs and symptoms of dehydration. Decreased skin turgor, dry mouth, and multiple longitudinal furrows in the tongue are symptoms of dehydration. Dehydration is a significant and common finding in geriatric and other patients in whom renal function has deteriorated.
- ▶ **Nutritional Considerations:** If appropriate, educate patients with low sodium levels that the major source of dietary sodium is found in table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through the consumption of processed foods. Patients on low-sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

Patient Education:

- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP.
- ▶ Recognize anxiety related to test results and answer any questions or address any concerns voiced by the patient or family.
- ▶ Educate the patient regarding access to nutritional counseling services.

- ▶ Provide contact information, if desired, for the Institute of Medicine of the National Academies (www.iom.edu).
- ▶ Teach the patient and family to recognize symptoms of both an excess and deficit of sodium.
- ▶ Teach the importance of fluid replacement with multiple diarrhea episodes.

Expected Patient Outcomes:

Knowledge

- ▶ States understanding that an altered sodium level can have a significant impact on cognitive function
- ▶ States understanding that excessive watery stools can result in an altered sodium level

Skills

- ▶ Identifies foods to select that will support a healthy sodium level
- ▶ Selects dietary supplements to what is required to support a healthy sodium level

Attitude

- ▶ Complies with the recommendation to monitor diarrhea and report excessive stools to the HCP
- ▶ Complies with the recommendation to increase oral fluid intake to replace lost fluids that can affect sodium levels

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, aldosterone, anion gap, ANP, BNP, blood gases, BUN, calculus kidney stone panel, BUN, calcium, carbon dioxide, chloride, chloride sweat, cortisol, creatinine, DHEAS, echocardiography, glucose, insulin, ketones, lactic acid, lung perfusion scan, magnesium, osmolality, potassium, renin, US abdomen, urine sodium, and UA.
- ▶ Refer to the Cardiovascular, Endocrine, and Genitourinary systems tables at the end of the book for related tests by body system.

Sodium, Urine

SYNONYM/ACRONYM: Urine Na⁺.

COMMON USE: To assist in evaluating for acute renal failure, acute oliguria, and to assist in the differential diagnosis of hyponatremia.

SPECIMEN: Urine (5 mL) from an unpreserved random or timed specimen collected in a clean plastic collection container.

NORMAL FINDINGS: (Method: Ion-selective electrode)

Age	Conventional Units	SI Units (Conventional Units × 1)
6–10 yr		
Male	41–115 mEq/24 hr or mmol/24 hr	41–115 mmol/24 hr
Female	20–69 mEq/24 hr or mmol/24 hr	20–69 mmol/24 hr
10–14 yr		
Male	63–177 mEq/24 hr or mmol/24 hr	63–177 mmol/24 hr
Female	48–168 mEq/24 hr or mmol/24 hr	48–168 mmol/24 hr
Adult–older adult	27–287 mEq/24 hr or mmol/24 hr	27–287 mmol/24 hr

Values vary markedly depending on dietary intake and hydration state.

DESCRIPTION: Sodium balance is dependent on a number of influences in addition to dietary intake, including aldosterone, renin, and atrial natriuretic hormone levels. Regulating electrolyte balance is a major function of the kidneys. In normally functioning kidneys, urine sodium levels increase when serum levels are high and decrease when serum levels are low to maintain homeostasis. Analyzing these urinary levels can provide important clues to the functioning of the kidneys and other major organs. There is diurnal variation in excretion of sodium, with values lower at night. Urine sodium tests usually involve timed urine collections over a 12- or 24-hr period. Measurement of random specimens may also be requested.

This procedure is contraindicated for: N/A

INDICATIONS

- Determine potential cause of renal calculi
- Evaluate known or suspected endocrine disorder
- Evaluate known or suspected renal disease
- Evaluate malabsorption disorders

POTENTIAL DIAGNOSIS

Increased in

- Adrenal failure (*inadequate production of aldosterone results in decreased renal sodium absorption*)
- Dehydration (*related to decreased water excretion, which results in higher concentration of the urine constituents*)
- Diabetes (*increased glucose levels result in hypertonic extracellular fluid; dehydration from excessive urination can cause hemoconcentration*)

- Diuretic therapy (*medication causes sodium to be lost by the kidneys*)
- Excessive intake
- Renal tubular acidosis (*related to diabetes*)
- Salt-losing nephritis (*related to diminished capacity of the kidneys to reabsorb sodium*)
- Syndrome of inappropriate antidiuretic hormone secretion (*related to increased reabsorption of water by the kidneys, which results in higher concentration of the urine constituents*)

Decreased in

- Adrenal hyperfunction, such as Cushing's disease and hyperaldosteronism (*overproduction of aldosterone and other corticosteroids stimulate renal absorption of sodium decreasing urine sodium levels*)
- Congestive heart failure (*decreased renal blood flow related to diminished cardiac output*)
- Diarrhea (*related to decreased intestinal absorption; a decrease in blood levels will cause sodium to be retained by the kidneys and will lower urine sodium levels*)
- Excessive sweating (*excessive loss of sodium through sweat; sodium will be retained by the kidneys*)
- Extrarenal sodium loss with adequate hydration
- Insufficient intake
- Postoperative period (first 24 to 48 hr)
- Prerenal azotemia
- Sodium retention (*premenstrual*)

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

- Drugs that may increase urine sodium levels include acetazolamide, acetylsalicylic acid, amiloride, ammonium chloride, azosemide, benzthiazide, bumetanide, calcitonin, chlorothiazide, clopamide,

cyclothiazide, diapamide, dopamine, ethacrynic acid, furosemide, hydrocortisone, hydroflumethiazide, isosorbide, levodopa, mercurial diuretics, methyclothiazide, metolazone, polythiazide, quinethazone, spironolactone, sulfates, tetracycline, thiazides, torasemide, triamterene, trichlormethiazide, triflocin, verapamil, and vincristine.

- Drugs that may decrease urine sodium levels include aldosterone, anesthetics, angiotensin, corticosteroids, cortisone, etodolac, indomethacin, levarterenol, lithium, and propranolol.
- Sodium levels are subject to diurnal variation (output being lowest at night), which is why 24-hr collections are recommended.

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.
- ▶ **Patient Teaching:** Inform the patient this test can assist in evaluating kidney function.
- ▶ Obtain a history of the patient's complaints, including a list of known allergens, especially allergies or sensitivities to latex.
- ▶ Obtain a history of the patient's endocrine and genitourinary systems, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Obtain a list of the patient's current medications, including herbs, nutritional supplements, and nutraceuticals (see Appendix H online at DavisPlus).
- ▶ Review the procedure with the patient. Provide a nonmetallic urinal, bedpan, or toilet-mounted collection device. Address concerns about pain and explain that there should be no discomfort during the procedure.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.

- ▶ Usually a 24-hr time frame for urine collection is ordered. Inform the patient that all urine must be saved during that 24-hr period. Instruct the patient not to void directly into the laboratory collection container. Instruct the patient to avoid defecating in the collection device and to keep toilet tissue out of the collection device to prevent contamination of the specimen. Place a sign in the bathroom to remind the patient to save all urine.
- ▶ Instruct the patient to void all urine into the collection device and then to pour the urine into the laboratory collection container. Alternatively, the specimen can be left in the collection device for a health care staff member to add to the laboratory collection container.
- ▶ Note that there are no food, fluid, or medication restrictions unless by medical direction.

INTRATEST:

Potential Complications: N/A

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Instruct the patient to cooperate fully and to follow directions.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen container with the corresponding patient demographics, initials of the person collecting the specimen, date, and time of collection.

Random Specimen (Collect in Early Morning)

Clean-Catch Specimen

- ▶ Instruct the male patient to (1) thoroughly wash his hands, (2) cleanse the meatus, (3) void a small amount into the toilet, and (4) void directly into the specimen container.
- ▶ Instruct the female patient to (1) thoroughly wash her hands; (2) cleanse the labia from front to back; (3) while keeping the labia separated, void a small amount into the toilet; and (4) without interrupting the urine stream, void directly into the specimen container.

Indwelling Catheter

- ▶ Put on gloves. Empty drainage tube of urine. It may be necessary to clamp off

the catheter for 15 to 30 min before specimen collection. Cleanse specimen port with antiseptic swab, and then aspirate 5 mL of urine with a 21- to 25-gauge needle and syringe. Transfer urine to a sterile container.

Timed Specimen

- ▶ Obtain a clean 3 L urine specimen container, toilet-mounted collection device, and plastic bag (for transport of the specimen container). The specimen must be refrigerated or kept on ice throughout the entire collection period. If an indwelling urinary catheter is in place, the drainage bag must be kept on ice.
- ▶ Begin the test between 6 and 8 a.m., if possible. Collect first voiding and discard. Record the time the specimen was discarded as the beginning of the timed collection period. The next morning, ask the patient to void at the same time the collection was started and add this last voiding to the container. Urinary output should be recorded throughout the collection time.
- ▶ If an indwelling catheter is in place, replace the tubing and container system at the start of the collection time. Keep the container system on ice during the collection period, or empty the urine into a larger container periodically during the collection period; monitor to ensure continued drainage, and conclude the test the next morning at the same hour the collection was begun.
- ▶ At the conclusion of the test, compare the quantity of urine with the urinary output record for the collection; if the specimen contains less than what was recorded as output, some urine may have been discarded, invalidating the test.
- ▶ Include on the collection container's label the amount of urine, test start and stop times, and any foods or medications that can affect test results.

General

- ▶ Promptly transport the specimen to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting health-care provider (HCP), who will discuss the results with the patient.

- ▶ Instruct the patient to resume usual diet, fluids, medications, and activity, as directed by the HCP.
- ▶ **Nutritional Considerations:** If appropriate, educate patients with low sodium levels that the major source of dietary sodium is found in table salt. Many foods, such as milk and other dairy products, are also good sources of dietary sodium. Most other dietary sodium is available through the consumption of processed foods. Patients on low-sodium diets should be advised to avoid beverages such as colas, ginger ale, sports drinks, lemon-lime sodas, and root beer. Many over-the-counter medications, including antacids, laxatives, analgesics, sedatives, and antitussives, contain significant amounts of sodium. The best advice is to emphasize the importance of reading all food, beverage, and medicine labels.
- ▶ Recognize anxiety related to test results. Discuss the implications of abnormal test results on the patient's lifestyle. Provide teaching and information regarding the clinical implications of the test results, as appropriate.
- ▶ Reinforce information given by the patient's HCP regarding further testing, treatment, or referral to another HCP. Answer any questions or address any concerns voiced by the patient or family.
- ▶ Depending on the results of this procedure, additional testing may be performed to evaluate or monitor progression of the disease process and determine the need for a change in therapy. Evaluate test results in relation to the patient's symptoms and other tests performed.

RELATED MONOGRAPHS:

- ▶ Related tests include ACTH, aldosterone, anion gap, ANP, BNP, blood gases, BUN, calcium, calculus kidney stone panel, carbon dioxide, chloride, chloride sweat, cortisol, creatinine, DHEAS, echocardiography, glucose, insulin, ketones, lactic acid, lung perfusion scan, magnesium, osmolality, potassium, renin, sodium, and UA.
- ▶ Refer to the Endocrine and Genitourinary system tables at the end of the book for related tests by body system.

Spondee Speech Recognition Threshold

SYNONYM/ACRONYM: SRT, speech reception threshold, speech recognition threshold.

COMMON USE: To evaluate for hearing loss related to speech discrepancies.

AREA OF APPLICATION: Ears.

CONTRAST: N/A.

This procedure is contraindicated for: N/A

POTENTIAL DIAGNOSIS

Normal findings in

- Normal spondee threshold of about 6 to 10 dB (decibels) of the normal pure tone threshold with 50% of the words presented being correctly repeated at the appropriate intensity (see monograph titled “Audiometry, Hearing Loss”)
- Normal speech recognition with 90% to 100% of the words presented being correctly repeated at an appropriate intensity

Abnormal findings in

- Conductive hearing loss
- Impacted cerumen
- Obstruction of external ear canal (*related to presence of a foreign body*)
- Otitis externa (*related to infection in ear canal*)
- Otitis media (*related to poor eustachian tube function or infection*)
- Otitis media serus (*related to fluid in middle ear due to allergies or a cold*)
- Otosclerosis
- High-frequency hearing loss (*normal hearing range is 20 Hz to*

20,000 Hz; high-frequency range begins at 4,000 Hz)

- Presbycusis (*related to gradual hearing loss experienced in advancing age, which occurs in the high-frequency range*)
- Noise induced (*related to exposure over long periods of time*)
- Sensorineural hearing loss (acoustic nerve impairment)
- Congenital damage or malformations of the inner ear
- Ménière's disease
- Ototoxic drugs (*aminoglycosides, e.g., gentamicin or tobramycin; salicylates, e.g., aspirin*)
- Presbycusis (*related to gradual hearing loss experienced in advancing age*)
- Serious infections (*meningitis, measles, mumps, other viral infections, syphilis*)
- Trauma to the inner ear (*related to exposure to noise in excess of 90 dB or as a result of physical trauma*)
- Tumor (*e.g., acoustic neuroma, cerebellopontine angle tumor, meningioma*)
- Vascular disorders

CRITICAL FINDINGS: N/A

Find and print out the full monograph at DavisPlus (<http://davisplus.fadavis.com>, keyword Van Leeuwen).

Stereotactic Biopsy, Breast

SYNONYM/ACRONYM: N/A.

COMMON USE: To assess suspicious breast tissue for cancer.

SPECIMEN: Breast tissue or cells.

NORMAL FINDINGS: (Method: Macroscopic and microscopic examination of tissue) No abnormal cells or tissue.

DESCRIPTION: A stereotactic breast biopsy is helpful when a mammogram or ultrasound examination shows a mass, a cluster of microcalcifications (tiny calcium deposits that are closely grouped together), or an area of abnormal tissue change, usually with no lump being felt on a careful breast examination. A number of biopsy instruments and methods are utilized with x-ray guidance. They include large-core needle biopsy (LCNB) that is used to remove a generous portion of breast tissue for examination, fine-needle aspiration biopsy (FNAB), or a vacuum-assisted needle biopsy device. An initial x-ray locates the abnormality, and two stereo views are obtained, each angled 15° to either side of the initial image. The computer calculates how much the area of interest has changed with each image and determines the exact site in three-dimensional space. The sample of breast tissue is obtained and can indicate whether the breast mass is cancerous. A pathologist examines the tissue that was removed and makes a final diagnosis to allow for effective treatment.

This procedure is contraindicated for

- ◆ Patients undergoing biopsy who have bleeding disorders because the site may not stop bleeding.

INDICATIONS

- A mammogram showing a suspicious cluster of small calcium deposits
- A mammogram showing a suspicious solid mass that cannot be felt on breast examination
- Evidence of breast lesion by palpation, mammography, or ultrasound
- New mass or area of calcium deposits present at a previous surgery site
- Observable breast changes such as “peau d’orange” skin, scaly skin of the areola, drainage from the nipple, or ulceration of the skin
- Patient preference for a nonsurgical method of lesion assessment
- Structure of the breast tissue is distorted

POTENTIAL DIAGNOSIS

- Positive findings in carcinoma of the breast

CRITICAL FINDINGS: N/A

INTERFERING FACTORS

Factors that may impair clear imaging

- Metallic objects (e.g., jewelry, body rings, dental amalgams) within the

examination field, which may inhibit organ visualization and cause unclear images.

- Inability of the patient to cooperate or remain still during the procedure because of age, significant pain, or mental status.

Other considerations

- Failure to follow dietary restrictions before the procedure may cause the procedure to be canceled or repeated.

- Consultation with a health-care practitioner (HCP) should occur before the procedure for radiation safety concerns regarding younger patients or patients who are lactating. **Pediatric & Geriatric Imaging** Children and geriatric patients are at risk for receiving a higher radiation dose than necessary if settings are not adjusted for their small size.

Pediatric Imaging Information on the Image Gently Campaign can be found at the Alliance for Radiation Safety in Pediatric Imaging (www.pedrad.org/associations/5364/ig/).

- Risks associated with radiation overexposure can result from frequent x-ray procedures. Personnel in the room with the patient should wear a protective lead apron, stand behind a shield, or leave the area while the examination is being done. Personnel working in the examination area should wear badges to record their level of radiation exposure.

- ▶ **Patient Teaching:** Inform the patient this procedure can assist in assessing breast health.
- ▶ Obtain a history of the patient's complaints or clinical symptoms, including a list of known allergens, especially allergies or sensitivities to latex or anesthetics, or sedatives.
- ▶ Obtain a history of the patient's reproductive system, symptoms, and results of previously performed laboratory tests and diagnostic and surgical procedures.
- ▶ Note any recent procedures that can interfere with test results.
- ▶ Record the date of the last menstrual period and determine the possibility of pregnancy in perimenopausal women.
- ▶ Obtain a list of the patient's current medications, including anticoagulant therapy, aspirin and other salicylates, herbs, nutritional supplements, and nutraceuticals, especially those known to affect coagulation (see Appendix H online at DavisPlus). It is recommended that use be discontinued 14 days before surgical procedures. The requesting HCP and laboratory should be advised if the patient regularly uses these products so that their effects can be taken into consideration when reviewing results.
- ▶ Review the procedure with the patient. Address concerns about pain related to the procedure and explain that some pain will be experienced during the test, or there may be moments of discomfort. Inform the patient that the procedure is performed in a special room, usually a mammography suite, by an HCP specializing in this procedure, with support staff, and takes approximately 30 to 60 min.
- ▶ **Sensitivity to social and cultural issues,** as well as concern for modesty, is important in providing psychological support before, during, and after the procedure.
- ▶ Explain that an IV line may be inserted to allow infusion of IV fluids such as normal saline, anesthetics, sedatives, or emergency medications.
- ▶ Instruct the patient to remove jewelry and other metallic objects from the area of the procedure.
- ▶ Instruct the patient to avoid taking anti-coagulant medication or to reduce

NURSING IMPLICATIONS AND PROCEDURE

PRETEST:

- ▶ Positively identify the patient using at least two unique identifiers before providing care, treatment, or services.

dosage as ordered prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant.

- ▶ Instruct the patient that, to reduce the risk of nausea and vomiting, solid food and milk or milk products have been restricted for at least 8 hr, and clear liquids have been restricted for at least 2 hr prior to general anesthesia, regional anesthesia, or sedation/analgesia (monitored anesthesia). The American Society of Anesthesiologists has fasting guidelines for risk levels according to patient status. More information can be located at www.asahq.org. Patients on beta blockers before the surgical procedure should be instructed to take their medication as ordered during the perioperative period. Protocols may vary among facilities.
- ▶ *Make sure a written and informed consent has been signed prior to the procedure and before administering any medications.*
- ▶ The procedure may be terminated if chest pain or severe cardiac arrhythmias occur.

INTRATEST:

Potential Complications:

Complications include cardiac arrhythmias; bleeding **related to a bleeding disorder, or the effects of natural products and medications known to act as blood thinners**; infection **that might occur if bacteria from the skin surface is introduced at the IV needle insertion site**; or seeding of the biopsy tract.

- ▶ Ensure that the patient has complied with dietary and medication restrictions.
- ▶ Ensure that anticoagulant therapy has been withheld for the appropriate number of days prior to the procedure. Number of days to withhold medication is dependent on the type of anticoagulant. Notify the HCP if patient anticoagulant therapy has not been withheld.
- ▶ Ensure the patient has removed all external metallic objects from the area to be examined prior to the procedure.

- ▶ Avoid the use of equipment containing latex if the patient has a history of allergic reaction to latex.
- ▶ Have emergency equipment readily available.
- ▶ Administer ordered prophylactic steroids or antihistamines before the procedure if the patient has a history of severe allergic reactions to any substance or drug.
- ▶ Instruct the patient to void and change into the gown, robe, and foot coverings provided.
- ▶ Observe standard precautions, and follow the general guidelines in Appendix A. Positively identify the patient, and label the appropriate specimen containers with the corresponding patient demographics, date and time of collection, and site location (left or right breast).
- ▶ Instruct the patient to cooperate fully and to follow directions. Instruct the patient to remain still throughout the procedure because movement produces unreliable results.
- ▶ Record baseline vital signs and assess neurological status. Protocols may vary among facilities.
- ▶ Establish an IV fluid line for the injection of saline, sedatives, or emergency medications.
- ▶ Place the patient in the prone or sitting position on an examination table. Cleanse the selected area, and cover with a sterile drape.
- ▶ A local anesthetic is injected at the site, and a small incision is made or a needle inserted.
- ▶ Instruct the patient to inhale deeply and hold his or her breath while the images are taken, and then to exhale after the images are taken.
- ▶ Instruct the patient to take slow, deep breaths if nausea occurs during the procedure. Monitor and administer an antiemetic agent if ordered. Ready an emesis basin for use.
- ▶ Monitor the patient for complications related to the procedure (e.g., allergic reaction, anaphylaxis, bronchospasm).
- ▶ Remove the needle or catheter and apply a pressure dressing over the puncture site.

- ▶ Observe/assess the needle/catheter insertion site for bleeding, inflammation, or hematoma formation.
- ▶ Place tissue samples in properly labeled specimen containers, and promptly transport the specimens to the laboratory for processing and analysis.

POST-TEST:

- ▶ Inform the patient that a report of the results will be made available to the requesting HCP, who will discuss the results with the patient.
- ▶ Instruct the patient to resume usual diet and medications, as directed by the HCP.
- ▶ Monitor vital signs and neurological status every 15 min for 1 hr, then every 2 hr for 4 hr, and then as ordered by the HCP. Take temperature every 4 hr for 24 hr. Monitor intake and output at least every 8 hr. Compare with baseline values. Notify the HCP if temperature is elevated. Protocols may vary among facilities.
- ▶ Observe for delayed allergic reactions, such as rash, urticaria, tachycardia, hyperpnea, hypertension, palpitations, nausea, or vomiting.
- ▶ Instruct the patient to immediately report symptoms such as fast heart rate, difficulty breathing, skin rash, itching, chest pain, persistent right shoulder pain, or abdominal pain. Immediately report symptoms to the appropriate HCP.
- ▶ Observe/assess the biopsy site for bleeding, inflammation, or hematoma formation.
- ▶ Instruct the patient in the care and assessment of the site.
